It may be of interest at this time to describe some of the more prominent of the new lines of 1898, using as a guide our weekly railway construction news columns, about one-half of the items in which are edited from official communications, and are, therefore, quite certainly accurate. It is not our intention to discuss the numerous more or less doubtful projects or such lines as have advanced no further than the surveys or grading. A number of these projected lines will doubtless be built, some of them, perhaps, before the close of another year, but this will depend entirely upon the financial backing which their promoters may succeed in securing.

One of the largest and most important pieces of work on this year's list of new construction is the Allegheny & Western Ry., which is to be an extension of the Buffalo, Rochester & Pittsburg R. R. From the old terminus of the main line at Punxsutawney, the new line will run to New Castle, via Adrian and Butler, Pa., a distance of 98 miles. Work is now well under way between Punxsutawney and Butler, and its farther extension to New Castle is projected in time to run trains over the entire route by next June. On this first section to Butler, a tunnel 2,317 ft. in length has just been finished, having taken five months to complete; track-laying has been commenced, and good progress is being made on the bridge, with a total length of 1,500 ft., which is to be built across the Allegheny River at Mosgrove. Excavation is progressing on a deep cut at Lyons farm, containing over 250,000 cu. yds. of material, and grading is active all along the stretch of six miles, from this cut to the Allegheny River, which is said to be one of the heaviest pieces of railway work in this country. Two steel viaducts will be built within 1½ miles of Adrian, one having a maximum height of 95 ft., and the other of 102 ft. At the "Devil's Gulch," one mile east of Adrian, there will be a steel culvert with a fall of more than 40 ft.; over this culvert there is an embankment 100 ft. high. In constructing this line the maximum grade employed is 1 per cent., compensated for curvature, and the rails used weigh 100 lbs. to the yard. The tunnel excavation and much of the grading and trackwork are being done by the Pennsylvania Construction Co., of Curwensville, Pa., under the supervision of Mr. J. M. Floesch, of Kittanning, Pa., as chief engineer.

Closely connected with the new Allegheny & Western R. R. is the Cleveland & New Castle extension of the Lake Erie & Western R. R., from Cuyahoga Falls to Youngstown, O., and thence to New Castle, Pa., a distance of about 80 miles. Contracts for the construction of this road were let in August in two sections, to Streeter & Co., of Chicago, for the portion between Akron and Niles, and to Ryan & McDonald, of New York, for the portion between Niles and New Castle. By means of the Allegheny & Western and this extension, the Brice system proposes to establish a new trunk line between Chicago and New York. The chief engineer of the Cleveland & New Castle extension is Mr. J. H. Pirkey, of Youngstown, O.

The Washington County R. R., in Maine, is also a project of considerable magnitude. This is an entirely independent line which, when completed, will connect Ellsworth and Calais, via Machias, Me., a distance of 116 miles. The work is being carried on in two sections, one of which, from Ellsworth to East Machias, a distance of 60 miles, has been mostly ballasted, while the other, extending to Calais, is being graded. Construction began about a year ago, and it was expected to open the first section for operation by Nov. 1, 1898. The company has acquired the St. Croix & Penobscot R. R., a short line running out of Calais, and it will also build a new branch from a point near Calais to Eastport. Besides opening up a new timber section in Maine, the line will make important connections with the Maine Central R. R. at Ellsworth, and with the Canadian Pacific Ry. and other Canadian railways at Calais. The promoters of the enterprise are Mr. George A. Curran, of Calais; and Mr. J. P. McDonald, of Knoxville, Tenn.; while Washington county assisted to the extent of $200,000 in bonds. Mr. William Barclay Parsons, of New York, was the chief engineer.

Two large railway extensions that have been completed this year are the Fosston branch of the Great Northern Ry., and the Kulm branch of the Minneapolis, St. Paul & Sault Ste. Marie Ry. The former line extends from Fosston to Deer River, Minn., and is 98 miles in length, and by means of the Duluth, Superior & Western Ry., which has recently been purchased, and another extension of 28 miles from Cloquet to the Nemadji River Bridge, this branch will gain an entrance into Duluth for the Great Northern Ry. and provide a continuouos line through northern Minnesota. Work was completed about the first of September. The Kulm branch, which was opened for traffic on October 17, runs from Kulm, in Le Moure county, to Hebard, Emmons county, N. Dak., a distance of 77 miles, where a junction will be made with the old grade of the Aberdeen, Bismarck & Northwestern Ry., which was partly graded in 1887 from Aberdeen, S. Dak., to Bismarck, N. Dak. The prime object of these two extensions is to accommodate the grain traffic from the Northwest to the Great Lake ports and the eastern seaboard.

In the southwest, one of the longest extensions is the St. Louis & Oklahoma City branch of the St. Louis & San Francisco Ry. The route is from Sapulpa, Ind. Ter., to Oklahoma City, via Stroud, Chandler and Wellston, a distance of 103½ miles. The contract to construct the line was let last February to Messrs. Johnston Bros. & Faught, of St. Elmo., Ill., who in turn sub-let the work to about a dozen contractors. On Aug. 1 our official reports showed that most of the grading has been completed, and about 75 miles of track laid. Mr. J. F. Hinckley, of Sapulpa, Ind. Ter., is the Chief Engineer.

The El Paso & Northeastern Ry. is another southwestern project well advanced towards completion. Starting from El Paso, Tex., on the Southern Pacific Ry., the line takes a northeasterly direction through a thinly settled region of New Mexico to White Oaks, at which place a junction is expected to be made with a projected extension of the Pecos Valley R. R. from Roswell. Of the entire distance of 165 miles, 86 miles are now ready for operation; work on the main line has stopped temporarily, it is stated, pending the construction of a 16-mile branch to timber lands across the route. Messrs. George S. Good & Co., of Lock Haven, Pa., received the contract for the work last December. The financiering of the project had not been entirely settled on October 1. The New Mexico Railway & Coal Co., of New York, which owns extensive coal mines in Arizona, is chiefly interested in this railway. Mr. H. A. Sumner, of El Paso, is chief engineer.

In California the most important work of the year is, doubtless, the final completion of arrangements which will insure the entrance of a new trans-continental railway into San Francisco, which city, notwithstanding the competition of its younger rivals in Southern California, and in Oregon and Washington, still remains the chief distributing center for the Pacific coast. All classes in California have long been restive under the monopoly of rail transportation in the state which the Southern Pacific Co. has long held, and the outcome was the building of the San Francisco & San Joaquin Valley Ry. in 1895, '6 and '7, extending from Stockton, on the Sacramento River, where steamer communication with San Francisco exists, southward about 235 miles through the most fertile farming section of California. During the present year the extension of the line from Stockton to San Francisco has been undertaken, and is now nearing completion, and arrangements have been completed by which the Atchison, Topeka & Santa Fe Co. acquires control of the road, and thus secures the entrance to San Francisco which it has for some time desired. To connect its present line with the new road, the Atchison will have to build an extension from its present terminus at Mojave to Bakersfield, or else secure trackage rights from the Southern Pacific for the use of its road between the two places.

The heaviest work on the Stockton-San Francisco extension is the "Franklin" tunnel, over a mile in length, now being driven through the Contra Costa Hills, 30 miles from San Francisco. Work is being carried on from both ends through a hard indurated clay, somewhat approaching slate, and considerable timbering is required throughout. Foley Bros. & Muir, of St. Paul, Minn., were awarded the contract in last February, and it was estimated that about 17 months would be required to complete the work.

The most important new line constructed in Canada is without doubt the extension of the Canadian Pacific Ry., by the construction of the Crow's Nest Pass and the Columbia & Western (Eng. News, March 10, 1898). Most of the track has now been laid on the Crow's Nest Pass line, from Lethbridge, N. W. Ter., to Nelson, B. C., at Kootenay Lake, a total distance of 287 miles. From Nelson to Midway a line is now in operation which will connect the new line with the Columbia & Western, now being built westward 105 miles. The completion of this latter line, and of a proposed branch from Midway to Penticton, and thence to Hope, will provide another transcontinental route much shorter than the present main line, which makes a long detour to the north.

The construction in this locality is of an extremely varied nature. The first 80 miles of the Crow's Nest Pass runs through what is called a prairie country, but it requires some heavy grading and much bridge work. On the next 25 miles the line reaches the summit of the Rockies, and there is considerable rock work. From the summit westward for 16 miles the work is also heavy, and includes two tunnels and a half-dozen bridges. The next 37 miles consists of earth and rock work, with a great deal of heavy clearing, and two 100-ft. bridges. Elk River is crossed by a three-span bridge, each span being 150 ft. long, and from here to the East Kootenay River and Wardner, about 23½ miles, the earthwork is again heavy, and three more bridges are required. From Wardner to Cranbrook, 23½ miles, the line passes through a park-like country, with the exception of five miles through the Isidores Canyon, where heavy rock excavation is again required. Thence to Moyie Lake, and along its east shore more difficulties are met with, requiring another 500-ft. tunnel, and then, after crossing the Moyie River and following the valleys for about 24 miles, another 35-mile section is reached requiring considerable excavation and trestle working. In this work the maximum grades are only 1%, and the maximum curvature, 12°. The manager of construction has been Mr. M. J. Haney, of Toronto, with headquarters at MacLeod, Alberta, N. W. Ter.

Turning now to a somewhat more general consideration of the geographical distribution of new railway construction, we find in the New England and the Middle Atlantic states a noticeable dearth of new work, other than that of the Washington County and the Allegheny & Western lines, already described. About 15 miles of new track have been laid in New York from Moira to the St. Lawrence River, by the New York & Ottawa Ry. This same company, however, has about 53 miles of new line on the Ontario side of the river, between Cornwall and Ottawa. In Pennsylvania several new branches and short extensions have been built to coal and timber districts. Such a line is the so-called Clearfield Southern, from Belsena Mills to Clearfield Bridge.

In the South Atlantic States, there are 40 miles of new work on the Richmond, Petersburg & Carolina Ry., and 22 miles on the Norfolk, Virginia Beach & Southern, in Virginia. The contract for constructing the Little Coal River Ry., a coal line 50 miles in length to be built in West Virginia, has been awarded, and in North Carolina, there has been about 125 miles of new track actually laid, with more to follow, on the Cape Fear & Northern, the Raleigh & Cape Fear, the North Carolina Midland, the Aberdeen & Ashboro, and the Carolina & Northwestern Rys. Extensions have also been built by the Carolina Midland Ry., in South Carolina; the Southern Ry., in Georgia, and to the Atlantic, Valdosta & Western Ry., in Florida.

In the Central Northern states most of the work has been in Ohio and Michigan on the Detroit & Lima Northern Ry., and its feeders. The building in the Gulf and Mississippi states has been more active. About 150 miles of track has thus far been laid in Alabama alone, with good prospects of more to follow before the close of the year. Among other lines being extended are the Alabama & Tombigbee, the Mobile, Jacksonville & Kansas City, and the Mobile & Ohio railways, which latter has completed its important connection between Jackson, Miss., and Birmingham, Ala., a distance of 167 miles, although most of the work of construction was carried on in 1897. The Yazoo Delta Ry., in Mississippi, has also been extended about 35 miles, and over 100 miles of track has been laid in Louisiana on the Louisiana & Northwestern, the Louisiana & Arkansas, the Southern Pacific and other lines.

In the southwest some of the railways which have added new mileage are the Kansas City, Osceola & Southern, from Osceola to Bolivia, 38 miles, in Missouri; the Arkansas, Louisiana & Southern, the Little River Valley and the Mississippi, Hamburg & Western Rys., in Arkansas, and the Colorado Valley, Chicago, Rock Island & Texas, and the Guadaloupe Valley railways, in Texas, which built in all about 150 miles. In Kansas extensions were built to the Kansas & Southeast, and the Hutchinson & Southern; in Colorado, to the Denver & Rio Grande and to the Golden Circle; in New Mexico, to the Pecos Valley, and in Oklahoma, to the Choctaw, Oklahoma & Gulf and other railways.

Of the Northwestern States, Minnesota has the greatest mileage of new track to its credit, viz., 175 miles, most of which is on the Great Northern Ry. In the other states of this section, extensions have been built to the Duluth, Mississippi River & Northern, the Muscatine, North and South, the Brainerd & Northern Minnesota, the Duluth & Northern Minnesota, the Gaylord & Ruby Valley branch of the Northern Pacific, and the Wyoming & Missouri River lines.

The work in the Pacific States, other than that on the San Francisco & San Joaquin Valley, which is most worthy of notice, is the 58-mile extension of the Gila Valley, Globe & Northern, from Geronimo to Globe, Ariz., a 17-mile extension of the Columbia Southern Ry., in Oregon, and the Union, Cove & Valley Ry., in Oregon. In Canada the only other company than the Canadian Pacific which has had important new extensions built is the Coast Ry., of Nova Scotia, which is being extended from Yarmouth towards Halifax.

In Mexico much important work has recently been done. President Diaz, in his annual message, delivered in the last part of September, states that since April the Mexican railway systems have increased by more than 314 kilometers (195 miles), of which 60 kilometers belong to the Mexican, Cuernavaca & Pacific; 60 to the Mexican Central, between Jiminez and Parral, which was later on completed for the whole distance of 89 kilometers on October 9; 40 to the Mexican National; 25 to the Mexican International on its branch between Reata and Monterey; and the remainder to other lines. Since this report, ten miles of track have also been laid on the proposed Chihuahua & Pacific Ry., which is being built by New York capitalists from Chihuahua to the Pacific coast, via Guerrero, a distance of 600 kilometers (372.6 miles).

LETTERS TO THE EDITOR.

The Advantages of Blower Systems for Drying Materials.

Sir: The letter of Mr. E. L. Ballard, in your issue of Nov. 3, regarding the use of blowing fans instead of steam pipes for drying tobacco, attracted our attention, and as your comment on it seemed to imply that heat was necessary the same with as without the fan, and the subject is one that should interest every one who has to do with drying brick, lumber, starch, leather, tobacco, etc., we wish to add to the remarks already made.

The drying of any substance is simply the absorption from it of a portion of its moisture by means of a dryer surrounding medium. The natural method of drying is by placing the substance in the air and allowing the moisture to be absorbed by the air. The proportion of moisture absorbed will depend either on the amount of moisture already in the air or on the quantity of air present. Now, the amount of moisture that the air is capable of absorbing increases with its temperature, and the quantity of air depends on the size of the room relative to the amount of moisture in the article to be dried or on the current of air that passes by, absorbing and carrying off moisture as it goes.

Man soon learned that drying was facilitated by heat, and until within a few years the commonly recognized method of hastening drying has been by heating the air by steam pipes or otherwise, and thus increasing the capacity of a given volume of air to absorb moisture. A blowing fan accomplishes the same object by increasing the volume of air passing by the article to be dried and at the same time allows of better regulation.

Any drying, to be successful, must begin slowly and be hastened only when the inside of the article has become partly dry, in order to prevent cracking the surface or staining it by the coloring matter in the water dried out of it. If the surface of the article is made dryer than the normal air in which it is to be used, it becomes "dead" and brittle and will never regain its natural elastic condition. Overdrying is much more apt to occur if done by heat than by a fan with air at normal temperature. Some thick articles like brick or lumber may require a certain degree of heat to start the moisture from the inside toward the surface, but thinner articles, like leather or tobacco, keep their elastic qualities better if dried at a low temperature, and this can only be done in all conditions of the atmosphere without moulding by a fan.

The secret of successful drying lies in the ability of the man who does it, not in the method. Some form of hygrometer is almost a necessity in the beginning, as the whole process of successful drying depends on the relative humidity of the air, or its substitute, regulation of quantity. In commercial drying, where the quantity of material to be dried is always placed in a comparatively small room, it is necessary to use heat or a fan to prevent moulding, but the principal consideration is time, and the intelligent use of a fan will do the drying in about half the time that would be needed with heat only, and leave the material in better condition.

Yours truly,
Given & Aldrich,
Civil and Mechanical Engineers.
Birmingham, Ala., Nov. 8, 1898.

Automatic Couplers for Air Brake Hose.

Sir: In your issue of Oct. 27, in discussing the merits of automatic air hose couplers, you say that "automatic car couplers were introduced largely to illiminate the danger to life and limb incident to coupling moving cars by hand, but the brake hose cannot be coupled until the cars are already coupled, and are very rarely coupled up while the cars are in motion in the yard." As a man having experience, I will endeavor to show you wherein you err, and that automatic hose couplers are not as unimportant as your article would indicate. To make a coupling with the old link and pin coupler was not much of a feat for an experienced man. In fact, good railway men would prefer them to the present mixture of types. Of course, when we get automatic car couplers universally introduced, this feature will be overcome. The facts are that the "protection of life and limb" is only incidentally an issue in the introduction of the automatic car coupler. Every trainman, however, looks forward with joy to the time when automatic car couplers will be the only couplers in use, and they also appreciate the fact that the danger of car coupling will be greatly eliminated when that time arrives, and do not so very much care what the motive may be for the improvement. However, to return to the air hose coupler, it may be imagined by those not actively engaged in the train service that air hose are not coupled or uncoupled while cars are moving. This, however, is a mistake, and I will endeavor to show you the necessity of improvement along this line, if the lives of human beings are worth an effort to save.

It is a fact that many lives are lost yearly by trainmen in making hose couplings, and any automatic arrangement that can be utilized will be hailed with delight by the writer. Five trainmen make a trip when cars are coupled and uncoupled without coupling and uncoupling hose when cars are moving. I have in my mind now two co-employees who were killed outright, one in coupling and the other in uncoupling hose. The one killed while coupling was doing so while the train was being made up in the yard, and in order to have the "air" ready to inspect when the train was "thumbs up." While making the coupling a "cut" of cars struck and caught him, drew him under and killed him. The other was uncoupling hose while the train was moving, and was caught by the wheel on the truck of the following car, drawn under and killed. Trainmen follow this practice to expedite the work, and as a rule they are the men who worked at railroading before air brakes came into use, consequently it seems to take so long and to consume so much unnecessary time to wait for cars to come to a stop before coupling and uncoupling hose, when compared with previous work when the automatic brakeman was unknown. For instance, you are switching a train, hose all coupled and train pipe charged, and you want to cut off one or more cars. You swing in with a foot on each brake beam, shut off the angle cocks, and reach down and lift up on the hose until it becomes uncoupled. Then all you have to do is to pull the pin and there you are, i. e., if you don't slip and fall under, then, there you are any way. You may say that this is unnecessary risk, but when the chief dispatcher is asking, "what is delaying you?" or "why don't you get out? You are laying out No. 150," or some other question familiar to "old timers," all kinds of schemes are resorted to in order to hasten the work and avoid a "jacking up," which is not pleasant. And this coupling and uncoupling of air hose is one of the schemes most commonly resorted to. So "all hail" to the automatic hose coupler. "Sivart."

Grand Junction, Colo, Nov. 5, 1898.

The Engineers' Work in the Santiago Campaign.

Sir: I was gratified to find in the Oct. 13 number of the Engineering News a valuable article by Mr. Chibas relative to the work of the engineers in the Santiago Campaign, accompanied by a well-done and useful map reduced from the official information showing the position of the troops in the vicinity of Santiago. I also note with satisfaction your editorial comment. As a matter of fact, much injustice has been done by some newspaper writers and others in commenting upon the practical work of the Santiago campaign, for the reason that the actual situation was hardly at all understood by others than those of the military authorities more immediately responsible for the execution of the military plans.

The Santiago campaign was a particularly rough, and, in a sense, hazardous enterprise, in a tropical region, meagerly known as to topographic details, at the sickly season, and with troops which, while they possessed mental and physical attributes of a high order and an admirable discipline, were ill prepared to meet the special difficulties of locality and climate. It was practically a race between the physical endurance and military spirit of the men and the destructive malarial influences that were lying in wait for them. It resolved itself into a question of time. Had full preparations for landing and movement, such as wharf and railroad, wagon road and bridge construction, been practicable, as in fact it was not, it would still have been entirely inexpedient to lose time on them. The work indicated would have taken at least a month under the most favorable circumstances, and the immediate consequence of this delay in completing the military enterprise would have been that the army would have been on its back prior to the surrender instead of after, and in all probability we should not have accomplished our results at all. In fact, the disembarkation of the troops was accomplished within 48 hours; and sufficient horses and mules to serve the immediate purpose, together with three days' rations, were put on shore in another day; and this included the transfer and disembarkation of 3,000 Cubans in addition to our own forces It will be admitted, I presume, after looking at the matter broadly, that the results sought in the campaign were in every sense thoroughly attained, and this after all is the main object of a military enterprise, and minor matters must be waived in the presence of an urgent military exigency.

For the comparatively rough engineering that was required, General Shafter had at his disposition his Corps Engineer, Colonel Derby, regularly assigned to him, and two companies of engineers in addition, including eight engineer officers with several others detailed at various headquarters, and these gentlemen performed in the fullest measure all the engineering work that was practicable or expedient, including the multiplied reconnoissance work, which, to great extent, was conducted under maximum topographical difficulties, and often under fire in the immediate presence of the enemy.

My own direct connection with this work, involving these minor details, was therefore unnecessary, and I was given command of a brigade at the front, where General Shafter believed that I could be of greater service to him. This enabled me to give personal attention to the military engineering proper, namely, the laying out and construction of the investing trenches, by which, in fact, the ultimate surrender of the Spanish army was finally compelled.

I state this in view of the paragraph below the middle of the third column on page 227 of Mr. Chibas' interesting and valuable article, in which he states that the trenches in the Santiago campaign were not laid out by the engineers, but were constructed by the troops of the line, under the direction of their own officers. While this is perfectly correct, it might lead to a misapprehension, because it so happened that my brigade held the extreme right, and I was specially charged by the division commander, General Lawton, with the designing and construction of the entrenchments.

I enclose you a copy of your map, which I have been glad to use as a matter of official record, a duplicate having been sent to the Adjutant-General and to the Chief of Engineers. On this map I have made certain corrections and additions.

First: Adding the position on the left of my line at Caney of the 2d Battalion of the 22d Infantry, one of the regiments in my brigade, occupying an extremely important point where it was enabled to completely cut off the retreat of the Spaniards by commanding the only possible means of exit by road.

Second: By adding the position occupied by General Sanchez's troops on the west side of the bay, across the Cobre Road. General Sanchez was under my orders and stationed in connection with my brigade.

Third: Showing the several positions (4 in number) occupied and entrenched by my brigade. A portion of the entrenchments between positions 1 and 2, and all of the entrenchments between positions 3 and 4, were also prescribed by me, and, to a considerable extent, executed by Cubans under my direction.

These matters are of interest to yourselves and to others as matters of engineering history and record, for which reason I have taken the liberty of communicating with you on the subject, and sending you the corrected chart, which is enclosed. Yours very truly,

William Ludlow,
Major-General, U. S. A.

Army Building, New York, Nov. 4, 1898.

(As it is practically impossible to reproduce and correct the maps published in our issue of Oct 13, we here attempt to verbally indicate the corrections and additions made by Gen. Ludlow, reference being made to the maps as published: In the first map, showing conditions on July 1, the position of the 2nd Bat., 22nd Infantry, at Caney, is changed to a point on the road leading from Caney to San Miguel. The camp of the 1st Brigade, 2nd Division, on June 30, is also shown on the Siboney road, at the south tributary to the Rio Seco, just east of La Reconda. On the map of July 14, the following additions are made: The headquarters of the Cuban General Sanchez are shown at Dos Caminos, on the Cobre Road, leading out of Santiago, and his troops occupied the point on this road marked "cemetery." Gen. Ludlow also indicates the four successive positions occupied by the 1st Brigade, 2d Division, on the dates named, as follows: (1) July 2 and 3, at San Juan Hill; (2) July 4 to 7, near position on map, marked by " Light U. S. Battery, 4 guns, Col. Theaker"; (3) July 8 to 10, at position marked or 12 I, field battery 71,"; (4) July 11 and Aug. 13, northwest of Santiago, with right wing resting on the "cemetery," and left wing extending to and including the 2d Mass. Regt.—Ed.)

Notes and Queries.

Apropos of the recent discussion in these columns of the relative resistance to corrosion of iron and steel, a correspondent writes that plumbers prefer iron to steel for underground or enclosed work, and states that iron stovepipes outlast those of steel by several years.

In publishing an abstract of the paper of Mr. A. L. Adams, M. Am. Soc. C. E., on "Wood Stave-Pipe," in our issue of Oct. 27, an error in numbering figures 1 and 2, in the paper as it appeared in the Transactions of the American Society of Civil Engineers, was reproduced in this journal. These figures should be transposed, and Fig. 1 should be Fig. 2, and Fig. 2 should be Fig. 1.

CONCRETE AND STEEL FLOORS FOR THE PETIT PALAIS DES BEAUX ARTS; PARIS EXPOSITION.

In the article with the above caption printed on p. 302 of our last issue, the illustration of the beam system of construction (Fig. 2) was accidentally omitted. We therefore insert it here and refer our readers to the second column of p. 302 in our preceding issue for a description of the construction. It may also be noted here that in the fourth paragraph of the article as printed, in stating the requirements of the test, it should have read that the "deflection" must not exceed 1-800th of the span, instead of the "rise."

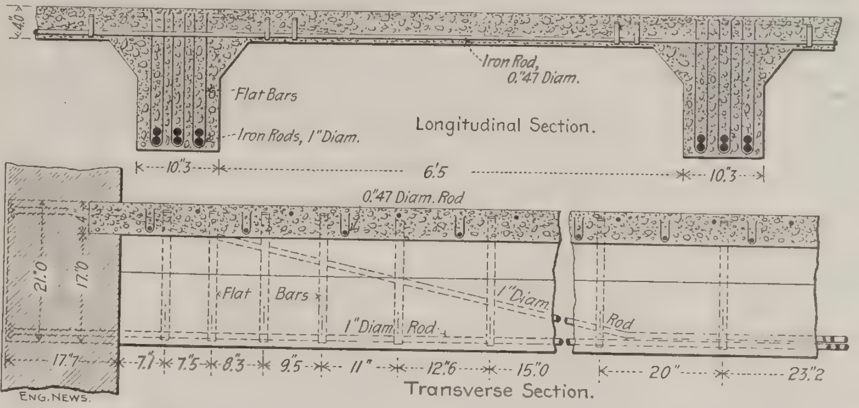

FIG. 2.—HENNEBICQUE BEAM SYSTEM OF STEEL AND CONCRETE FLOOR CONSTRUCTION FOR THE PETIT PALAIS DES BEAUX-ARTS FOR THE PARIS EXPOSITION OF 1900.

NOTES FROM THE ENGINEERING SCHOOLS.

University of Illinois.—A visit to the Engineering Department of the University was made on Nov. 11 by a large number of the members of the Western Society of Engineers and other visitors, including several of the trustees of the University. The party came by a special train on the Illinois Central R. R., arriving at 1 p. m., and leaving again at 6.30 p. m. At the engineering building the visitors were received by President Draper and the staff of professors, and luncheon was served in the physics laboratory.

The party was conducted through the building and then through the woodworking shops, machine shops, electrical and mechanical engineering laboratories, laboratory of applied mechanics, the new central boiler-house for the heating plant, and finally to the new library building, which was designed by Prof. Ricker, Dean of the College of Engineering, and one of the earliest graduates of the university.

The party was conducted by President Draper, assisted by Professors Baker, Breckenridge, Pence and others. After a tour of inspection, the party assembled in the physics lecture room, and brief speeches were made by the President, and by Messrs. L. P. Morehouse, Richard Price Morgan, R. W. Hunt, Isham Randolph, H. W. Parkhurst and Prof. I. O. Baker.

Massachusetts Institute of Technology.—The new building just erected for the use of the Institute will be called the Pierce Building, in honor of the late Hon. Henry L. Pierce. Mr. Pierce was a member of the Corporation from 1885 until the time of his death. He was a leader in a line of business making large demands on science; and he always expressed a keen interest in the Institute, its ideas and work, as shown by visits and suggestions, and by his frequent and liberal gifts. His various benefactions amount to $770,000 to Oct. 31, 1898.

The circular of the Lowell Free Courses in the Institute of Technology is now ready for circulation. Among the timely courses given are: "The Structure and Strength of Ships," by Prof. Peabody; "The Computation of Earth Work," by Prof. Allen; "Sanitary Science and the Public Health," by Prof. Sedgwick; "Mechanism and Gearing," by Prof. Merrill; "English Composition," by Prof. Bates; and the usual mathematical courses and electrical testing laboratory exercises by Prof. Laws.

University of Nebraska.—The north wing of a new building, known as "Mechanic Arts Hall," has been dedicated with appropriate exercises, including addresses by President Chaplain and by Morgan Brooks, the recently-appointed professor of electrical engineering. The building is of brick, plain, but substantial, and cost a little over $30,000. It will require at least $60,000 more to complete it as planned.

Prof. O. V. P. Stout, head of the civil engineering department, who has been engaged throughout the summer and fall in constructing a flume and power station for the Ingold Placer Mining Co., of Boulder, Colo., is now at his place in the University. Adjunct-Prof. Geo. R. Chatburn has had charge of the department during his absence.

THE NEW U. S. BATTLESHIP "MAINE."

(With two-page plate.)

At the annual meeting of the Society of Naval Architects and Marine Engineers, held in New York last week, a paper was presented by Commodore Philip Hichborn, Chief of the Bureau of Construction and Repair, U. S. N., on "Designs of the New Vessels for the U. S. Navy." We reprint that portion of it relating to the three new battleships, recently placed under contract, in full below, and have reproduced upon our inset sheet the drawing of the new "Maine," which accompanied Commodore Hichborn's paper:

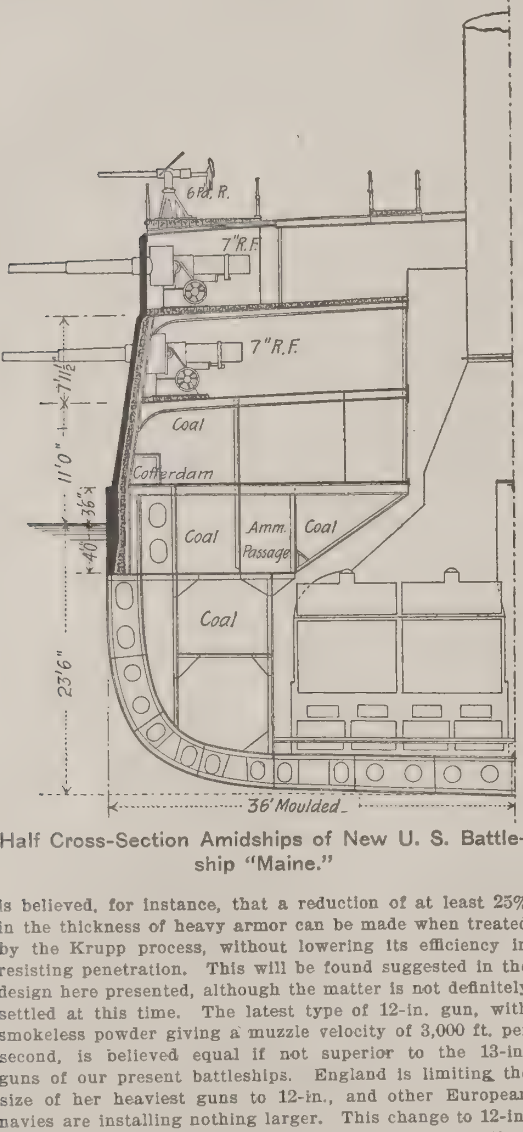
Believing that the "Alabama" class represented an efficient type, the Department, in issuing circulars and plans for the three battleships appropriated for, concluded practically to duplicate that class as regards size, speed, armament, etc. It was decided, however, to invite bidders to submit their own designs, offering preference—other things being equal—to bids guaranteeing the highest rate of speed and greatest coal endurance, without exceeding the total weight of engines, boilers and coal, or the space allowed therefor, as provided in the Department's plans and specifications.

The result was highly satisfactory. The designs submitted, after some revision, provided, in effect, an 18-knot vessel 20 ft. longer and of 1,000 tons greater displacement, but in other respects conforming to the original plans and specifications, excepting, of course, the changes in design of boilers and engines to meet the additional requirements of power on the weight allowed.

The preliminary acceptance of these propositions had to be followed by a revision of plans and specifications before any contract could be drawn. At the time of preparing my paper this work was still in the hands of the builders, and I regret having been therefore unable to obtain plans and particulars as complete as I should have liked. General plans of the "Maine," intended to accompany the contract, were received in time to allow their utilization in illustrating the paper, and will be found appended. While there will probably be some variation from these plans in the other vessels, as regards the type of boilers and engines, they may be considered as fairly representing the class, and an examination will show that, in general, the vessels will be enlarged and speedier types of the "Alabama."

General dimensions and particulars of this design are tabulated below. As remarked in the introduction, however, very little of this information can be considered as absolutely accurate or fixed, as a great deal of it is the result of only the preliminary design and calculations. The machinery details, it must be remembered, are for one of the three designs only.

A clause in the contract provides suitably for the making of certain changes in armor and armament, within six months, such changes being suggested by recent developments in the manufacture of armor and guns. It is believed, for instance, that a reduction of at least 25% in the thickness of heavy armor can be made when treated by the Krupp process, without lowering its efficiency in resisting penetration. This will be found suggested in the design here presented, although the matter is not definitely settled at this time. The latest type of 12-in. gun, with smokeless powder giving a muzzle velocity of 3,000 ft. per second, is believed equal if not superior to the 13-in. guns of our present battleships. England is limiting the size of her heaviest guns to 12-in., and other European navies are installing nothing larger. This change to 12-in. guns is therefore to be expected in the designs in question, and the number of 6-in. guns will, of course, be increased as a consequence—probably to 16. The secondary battery provided in the "Maine" design has been increased over that of the "Alabama" class, on account of increase in the length of the vessel. The number of 6-pdr. guns stated may also be changed somewhat.



Half Cross-Section Amidships of New U. S. Battleship "Maine."

One very important improvement in the new battleships will be the installation of under-water torpedo tubes. There will be two of these submerged tubes in a single compartment fitted up for the storage of eight 17-ft. torpedoes and appliances for handling and operating the same. The war heads will be conveniently stowed in a separate compartment. We have been rather tardy in adopting the submerged discharge for torpedoes, but the matter has been made the subject of considerable study and some experiment, so that it is to be hoped that our first attempt at this difficult installation will be more successful than some of the early efforts of European designers in this connection.

It is interesting to note, under the schedule of weights given below, which represents the vessel in trial condition, in which she is to attain a speed of 18 knots, the relatively large amount of coal, ammunition and stores to be carried on trial. The total coal bunker capacity is also very large, it being fixed at 2,000 tons. This, of course, involves the closest possible stowage, and the figures cannot therefore be compared with those based on loose stowage, as given out for our previous battleships. It will also be seen by comparison between the estimated collective I. HP. and the total heating surface of the boilers, that the number of square feet of heating surface per horse-power is over 3.6. These figures, of course, are only estimates as yet.

Considered as a whole, however, the "new designs" for battleships—with the slightly lengthened hull and general arrangement of the "Alabama" class, with the immense addition in engine power, and with the improved armor and armament likely to be fitted—certainly embody the very best features known to naval science. It is of special importance that the improvements in design have been accomplished with practically no sacrifice in draft, in which respect these ships will have an advantage of from 18 ins. to 2 ft. over vessels of their same class and size in Europe. The fact that the contract price for hull and machinery for the "Maine" class will exceed by less than 10% that of the "Alabama" class speaks well indeed for the progress of the shipbuilding art in this country. The contract time, furthermore, has been reduced.

Dimensions and Particulars.

Hull.

Length on load water-line	388 ft.
Length over all	393 " 9 ins.
Breadth, molded....72 ft.; extreme	72 " 2½ "
Freeboard, forward	20 "
Freeboard, aft..13 ft. 3 ins.; amidship	20 " 3½ "
Mean draft, with 1,000 tons coal and all stores and ammunition	23 " 10¼ "
Corresponding displacement (trial)	12,500 tons.
Speed per hour in knots	18
Area amidship section	1,637 sq. ft.
Area load water plane	21,000 " "
Tons per inch immersion	52
Moment to alter trim 1 in	1,050 ft. tons.
Wetted surface	35,572 sq. ft.
Mean draft, with all provisions, stores, ammunition, and 2,000 tons of coal on board	25 ft. 6 ins.
Corresponding displacement	13,500 tons.
Metacentric height (at 25 ft. 6 in. draft)	4.20 ft.
Range of stability at same	68°
Maximum righting arm	2 ft. 5 ins.
Maximum righting moment	32,535 ft. tons.
Angle of maximum righting arm	36°

Armament.

Main battery	4 13-in. B. L. R., 14 6-in. R. F.
Secondary battery— 20 6-pdr. R. F., 6 1-pdr. R. F., 4 Gatlings, 1 field gun.	
Height of guns above 23 ft. 10¼ in. L. W. L.:	
Axis of forward 13-in. guns	26 ft. 1½ ins.
Axis of after 13-in. guns	18 " 7½ "
Axis of 6-in. guns, main deck	15 "
Axis of 6-in. guns, upper deck	22 " 4½ ins.

Thickness of Armor.

Water-line belt, amidships:	
To 1 ft. below 23 ft. 6 in. L. W. L.	12 ins.
Bottom	8½ "
Height above 23 ft. 6 in. load line	3 ft. 6 "
Total depth of belt	7 " 6 "
Side armor above main belt	5½ "
Superstructure armor	6 "
Turret armor (13-in. gun)	17 and 15 "
Barbette armor	15 " 10 "
Protective deck armor	2¾ to 4 "
Conning tower armor	10 "

General Schedule of Weights.

Hull and fittings	4,836 tons.
Armor and bolts	2,933 "
Protective deck armor	600 "
Armament and ammunition	1,058 "
Machinery, with water	1,396 "
Equipment	199 "
Outfit and stores	478 "
Coal	1,000 "
Total	12,500 tons.

Machinery.

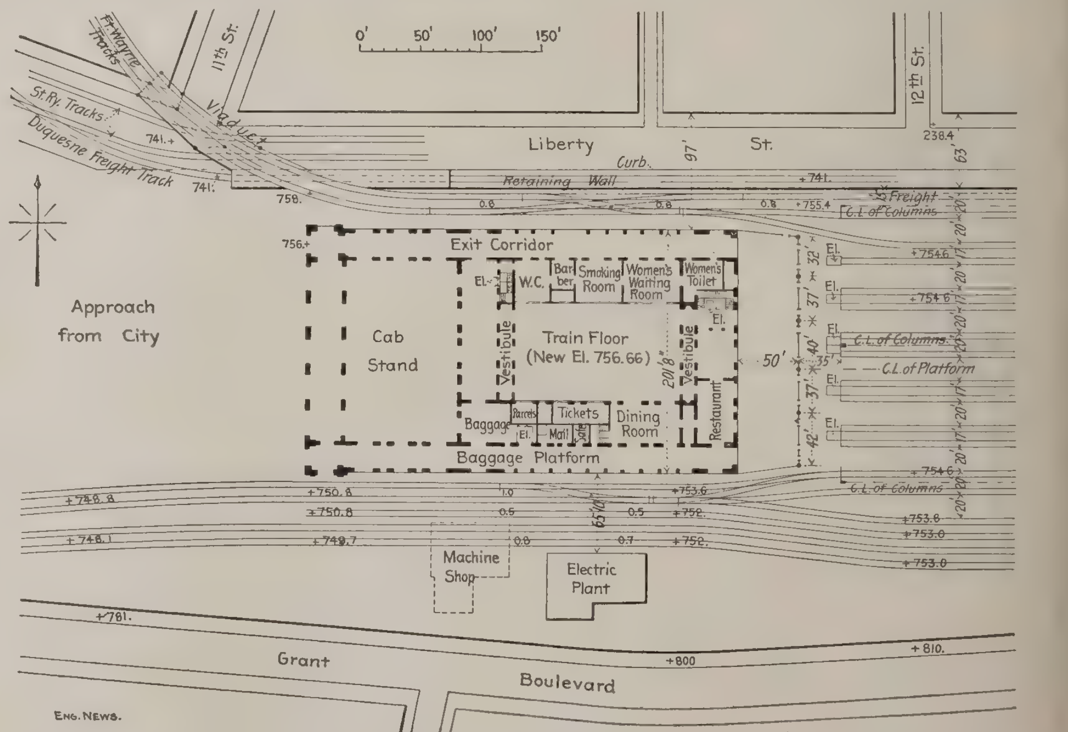
Vertical, inverted cylinder, direct-acting, triple expansion engines, in two water-tight compartments:	
Collective I. HP. of propelling, air-pump, and circulating-pump engines.	16,000
No. of revolutions at this power	126
Cylinder diams., ins	38½, 59 and 92
Length of stroke, ins	42
Cooling surface, main condenser	9,600 sq. ft.
Cooling surface, auxiliary condenser	800 " "

Boilers.—24 Niclausse water-tube type, in three groups of 8 boilers each. Each group is subdivided by the center line bulkhead. Each boiler will have 15 elements of 24 tubes, the whole number of elements being 360 and the number of the tubes 8,640.

Total heating surface	58,104 sq. ft.
Total grate surface	1,353 " "
Working pressure (gage) lbs. per. sq. in.	250

NEW STATION OF THE PENNSYLVANIA R. R. AT PITTSBURG, PA.

The Pennsylvania R. R. has for several years past been expending vast sums of money upon the improvement of its road and its terminals, and is now about to undertake the reconstruction of its Pittsburg terminals at a cost of probably over $1,500,000. This work will include the elevation of its tracks through the city, and the construction of a handsome new station on the site of the present station. We show a general plan of the new arrangement, from which it will be seen that there are to be both through and stub tracks, the station building having tracks on three sides, with the street approach on the other side. The main floor of the new station will be about 12 ft. above that of the present structure, and the elevations of the different tracks, etc., are marked upon the plan. The Pennsylvania R. R. proper comes in at the east end of the station. The Pittsburg, Fort Wayne & Chicago Ry. comes in from the northwest, crossing the Allegheny River. The Pittsburg, Cincinnati, Chicago & St. Louis Ry. comes in from the southwest, crossing the Monongahela River.



GENERAL PLAN OF NEW TERMINAL AND STATION FOR THE PENNSYLVANIA R. R. AT PITTSBURG, PA.

Wm. H. Brown, M. Am. Soc. C. E., Chief Engineer D. H. Burnham, Architect.

On the Liberty St. side will be two through tracks of the Pittsburg, Fort Wayne & Chicago Ry., brought in on a curve from 10th St. and the Allegheny River bridge. These tracks cross Liberty St. by a viaduct. One of them will be a freight track, outside the trainshed. The other will run through the trainshed, and will also connect with another passenger track. A double crossover will facilitate train movements. There will be a retaining wall along Liberty St., the street level being 14.4 ft. below that of the tracks. The Duquesne freight track will remain at the street level, being separated from the roadway by a curve, and will cross the tracks of the street railway just beyond the station.

On the Grant Boulevard side of the station will be four through tracks, two of which will be entirely independent of the station tracks, while the other two will connect with two of the station tracks by means of crossovers. This side of the station is against the slope of the hill, Grant Boulevard being from 30 to 55 ft. above the tracks. On this side of the building will be the electric power station.

The trainshed will be 550 ft. long and 225 ft. wide c. to c., of the outer lines of columns. It will cover twelve tracks, and six platforms, each of the latter being 20 ft. wide. There will be three through tracks and nine stub tracks in the trainshed, with baggage elevators at the ends of the latter. A transverse platform 85 ft. wide extends from the headhouse to the ends of the tracks, for the full width of the building, and at 50 ft. from the headhouse is an iron fence with gates. This forms a 50-ft. concourse to effect a distribution of the crowds and serve as an auxiliary to the waiting room.

The station proper or main building, will be about 360 ft. long and 201 ft. 8 ins. wide, with a height of four stories in the main portion, 235 × 155 ft. At the city approach, and extending the full width of the building, will be a covered way about 25 ft. wide, opening into a carriage concourse, 90 × 150 ft., beyond which is a vestibule containing entrances to the main waiting hall and to the baggage room. In the center of the main building will be a grand hall or waiting room, 135 × 80 ft., with a vestibule at each end, one opening upon the street entrance and the other upon the main platform or concourse. On one side of this hall will be the railway and sleeping-car ticket offices, parcel room, dining room, restaurant, mail room and baggage room. Beyond these will be a covered baggage platform about 20 ft. wide. On the other side of the main hall will be the smoking-room, women's room, toilet rooms and barber shop, outside of which will be a corridor 20 ft. wide for passengers going from the trains to the street. In each side of the building will be stairways and elevators communicating with the several floors.

While this general interior arrangement is a very common one, it seems to us to be open to serious objection in that it makes the waiting room the main thoroughfare to the trains and the principal place for the transaction of business. Passengers who are waiting for trains are, therefore, continually disturbed by the noise and bustle, and while there is a separate waiting room for women, there will be apparently no place where men who are sick, weak or weary can rest in quiet. It seems to us that it would have been better to make this great hall narrower, with ticket, parcel and news rooms opening upon it, and with waiting rooms separate from it. This general arrangement has been adopted in some stations, notably in the Park Square station at Boston, much to the comfort and convenience of the traveling public.

The approach will be a broad space paved with asphalt, and it is proposed to run branch tracks from the street railway on Liberty St. up to one side of the station.

The entire planning of the new terminal system, with its station and track elevation, has been done under the direction of Mr. Wm. H. Brown, M. Am. Soc. C. E., Chief Engineer of the Pennsylvania R. R., to whom we are indebted for the plan and the view of the building. The architectural design was prepared by Mr. D. H. Burnham, of Chicago.

The stations and trainsheds of the Pennsylvania R. R. at Jersey City and Philadelphia have been described and illustrated in our issues of Dec. 27, 1890; Sept. 26, and Oct. 3, 1891; Oct. 6 and 13, 1892, and June 1 and 8, 1893.

A CHAIR OF MUNICIPAL ENGINEERING and a lectureship of municipal hygiene has been established at University College, London, under provisions made by that eminent sanitarian, the late Sir Edwin Chadwick. Prof. Osbert Chadwick, M. Inst. C. E., son of the founder, remarked during the exercises accompanying the ceremony, that the title of sanitary engineer has been appropriated by the plumber and glazier, making the title, municipal engineer, necessary as a substitute.

◆

THE CIVIL SERVICE EXAMINATION to select two electrical engineers, announced on page 289 of our last issue, has been cancelled by the Civil Service Commission. Hereafter the subject of electrical engineering will be optional in junior civil engineer examinations for the Engineer Department at Large (War Department), so that persons qualified as electrical engineers may have an opportunity to have their qualifications tested. The junior civil engineer examination will be given next spring. Applications and information in regard thereto may be obtained after Jan. 15, 1899..

◆

THE LAKE SUPERIOR & MICHIGAN CANAL CO. is being incorporated at Lansing, Mich., and surveys are being made. The chief promoters are Messrs. D. C. Dennison, A. H. Parker and C. W. Parker, all of Chicago. They hope to utilize a glacial valley occupied by a series of swamps, and estimate the cost of the canal at about $4,000,000. But Mr. L. E. Cooley says that the best topographical maps show a divide between the two lakes about 300 ft. high; and it would not pay to lock over this divide, even if water were available—which he doubts.

◆

THE TENNESSEE RIVER IMPROVEMENT ASSOCIATION will hold its annual meeting at Chattanooga, on Nov. 23; General Joseph Wheeler is President, and will preside.

◆

TWO CAST-IRON LIGHT-HOUSES are to be erected on the Norwegian coast, at Okso and Utvar. Each will be 85.28 ft. high and 27.22 ft. in largest outside diameter, tapering to 14.76 ft. at the top. Besides a basement ring, each will be made of 16 sectional rings of cast-iron bolted together; the plates will be 30 mm., or 1⅓ ins. thick at the bottom, and for other courses 1.1 ins. The rings have inside flanges, 12 plates to the circle.

◆

NEW OCEAN STEAMER TRACKS, for North Atlantic vessels, have been adopted by the steamship managers, as the result of a recent conference in London. Two, instead of three tracks, as at present, were decided upon. From Jan. 15 to Aug. 14 the west-bound track will be from Fastnet, or Bishop's Rock, on the great circle course, to the crossing of meridian 47° W., in latitude 42° N.; thence, by either rhumb line or great circle, to a position southward of Nantucket lightship; thence to Fire Island, when bound for New York; or to the Five Fathom Bank South lightship when bound for Philadelphia. From Aug. 15 to Jan. 14, the westward course would cross meridian 49° W., in latitude 43° N. The eastward course, at all seasons of the year, would cross meridian 70° W., at latitude 40° 10′ N. From this crossing, from Jan. 15 to Aug. 23, the course would cross meridian 47° W., in latitude 41° N., to Fastnet, or to Bishop's Rock. From Aug. 24 to Jan. 14, the latter course would cross meridian 60° W., in latitude 42° N.; thence by rhumb line to cross meridian 45° W., in latitude 46° 30′ N.; thence to Fastnet or to Bishop's Rock, as the course lies for the Irish or the English Channel. All of the steamship lines agree to this arrangement.

MEETING OF THE SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS.

The 6th annual meeting of this society was held Nov. 10-11, at the House of the American Society of Mechanical Engineers, in New York city.

At 10.30 a. m. President Clement A. Griscom called the meeting to order, and Secretary Francis T. Bowles read his report, which also included the financial status of the society. He stated that 50 applications for membership had been received, and that there was a balance of $7,000 in the society's treasury. The list of candidates presented by the Council was passed upon by acclamation, after which the officers for the past year were re-elected, Mr. G. W. Dickie, of the Union Iron Works, being substituted for the late John F. Parkhurst, as member of the Council. Following this, Mr. Griscom, the president, read a brief address, in the course of which he said:

> The past year has been one of exceptional interest to the members of the society. The laurels won on the decks of the warships built in the shipyards of the United States have electrified the world, and the marvelous victories gained reflect credit which can well be shared by our gallant naval officers with the designers and builders of the ships, which they commanded.
>
> The demands made by the government in the war with Spain for colliers, water boats, troopships, hospital ships, supply vessels, guard boats, blockading vessels, scout and cruisers largely exceeded the supply found in our merchant marine. The navy purchased about 110 vessels of various classes, and the War Department chartered and purchased about 100 important steamships, and these 200 vessels, ranging in size from yachts to ocean liners, were fitted for war purposes with incredible despatch, and upon the whole in a most effective manner.
>
> An enormous public interest has been awakened in the performance of this so-called "Auxiliary Navy," and the practical lesson the country has received from the late war leads me to repeat what I had the honor of saying to you in 1894.
>
> It should be understood that a modern naval force, with all its multitude of equipment, arms, munitions and accessories, cannot be produced on the spur of the moment, but is the product of naval architects, steel makers, and a host of others whose skill can only be obtained by experience. It must not be overlooked that the personal element in warfare as in peace is an all-powerful one, sometimes predominating, sometimes secondary, but always of the greatest importance, and, therefore, an adequate navy is necessary, not only for the actual representation of power and force, but also to secure to our officers and men that superior nautical training only to be obtained by such continued experience at sea as made heroes of Hull, Decatur and Farragut.
>
> The full development of a naval force, however, is not possible unless the growth of the merchant marine has kept pace with the naval development. The words of Sir Nathaniel Barnaby, "No nation can maintain an efficient navy without a prosperous commercial marine to support it," has still the force of an axiom. It should not be overlooked that, in time of war, the conversion of fast mail steamers into armed cruisers is generally recognized among all maritime nations as a most formidable means of offence or defence for any country so fortunate as to possess them; moreover, to provide for the expansion of naval personnel rendered necessary in time of war, there must be a well-trained merchant marine to draw upon, and those nations which have not encouraged shipbuilding and shipowning in times of peace must inevitably suffer from their shortsighted and narrow policy when confronted with a powerful hostile fleet.
>
> It is not too hopeful to predict that one of the results of the war, resulting in the acquisition of distant insular territory, will exercise a marked effect upon our shipbuilding industry; indeed, it may be the turning point from which this nation may commence to regain its once proud position as a shipbuilding, shipowning and seafaring people; and it is very happy testimony to your skill as naval architects and marine engineers that several orders have already come from foreign nations for warships of the first class, and it is well known that foreign shipbuilders and capitalists have commenced seriously to examine with interest the advantages of this country for shipbuilding.

The reading of papers began with one by Mr. Arthur B. Cassidy, entitled, "The Standard Navy Boats." This paper briefly reviewed the various types of small boats, such as dories, whale boats, surf boats and the like, and then described the several types of steam launches and boats now adopted by the United States Navy Department as standard for use on all naval vessels.

In the design of these boats the four essentials in order of importance are: Safety, weight, comfort and speed. Just how these requirements are met was fully explained, as were also a number of constructional details. Two tables were included; one, giving the maximum number of men, weight of provisions and water and freeboard, when loaded, of the standard described; and the other giving the sail area, area of load water line, etc., for the same boats. These figures range from 64 men, 640 lbs. of provisions and 505 sq. ft. of sail for the 33-ft. launches, to 10 men, 100 lbs. of provisions, and 126 sq. ft. of sail for the 18-ft. dinghies. The statement was also made that at present there were in use in the navy 1,000 boats of all classes, the life of any one of which would not average more than 10 years. Accompanying the paper were 21 plates giving the constructional details of a number of designs of each type of boat mentioned, and 16 full-page half tones, taken from actual boats.

The discussion was introduced by Mr. H. De B. Parsons, who asked what the author's experience with folding boats had been. Such boats were used by foreign navies, and also by the merchant marine. Mr. W. P. Stephens remarked that the area of sail provided appeared small, and it seemed to him could be increased with material advantage.

Capt. J. W. Miller also considered an increased sailing power desirable, and he suggested the use of a centerboard with suitable stiffening. His experience with 12 boats used in connection with the New York naval militia convinced him that the boats now used were not good sailers.

Col. E. A. Stevens asked if metal boats had been tried by the navy. He also understood that cypress planking was at one time used, but that it had been abandoned, and wanted to know why.

Lieut. W. P. White mentioned a report of a board appointed to investigate the question of small boats which was published in the "Proceedings of the Naval Institute." He considered that the rig of these boats needed attention. It was unnecessary to adopt small sails for safety since safety depended largely upon the handling and not upon sail area.

Mr. John G. Tawresey said that there were so many conflicting elements to be provided for in the design of these boats that it was difficult to suit all. Injuries in stowage, hoisting and lowering, and the blast of guns all tended to shorten the life of boats. At present he had charge of the largest boat shop in the navy, and he was therefore in a position to appreciate the excellence of the present type. Metal boats had been tried in the navy and abandoned. Centerboards were not used because of the additional weight and the infrequent need of sailing close to the wind. It must be remembered that these boats are not intended for sailing craft. The present designs suited three out of four officers.

Secretary Bowles said the present boats were the outcome of an enormous amount of experience and were a compromise between the builder and the user, whose ideas were naturally somewhat antagonistic.

The second paper, by Assistant Naval Constructor Lawrence Spear, U. S. N., entitled "Bilge Keels and Rolling Experiments, U. S. S. 'Oregon,' " was then read by Prof. W. F. Durand. It is abstracted separately on another page of this issue. The discussion was opened by Mr. J. G. Tawresey, who said that the arguments advanced for abandoning the bilge keel did not meet the approval of practical men. That the reduction of rolling was due to wave making by the bilge keels there could be little doubt, and it is well known that the best method of creating model waves was by oscillating a plane. He considered that the bilge keels did not disturb to any extent the natural wave lines of the vessel.

Prof. W. F. Durand read a discussion of the paper, calling attention to the difference in results obtained by the use of present formulas and the actual values obtained by the test described. The bilge keel was not a plane, and the formulae at present in use were very unsatisfactory.

Secretary Bowles stated that a few years ago bilge keels were placed on all of the large vessels of the navy. Recently, for various reasons, several battleships had been built and launched without these keels, with the result that these vessels were not really safe, and it was necessary that keels be put upon them. He ventured to say that in the future no battleships would be built without bilge keels.

Asst. Naval Constructor R. M. Watt mentioned that the "Massachusetts," was keeled in 16½ working days at the Brooklyn Navy Yard, under Mr. Bowles.

The next paper, "Portable Pneumatic Riveters in Shipbuilding," was then read by its author, Mr. W. I. Babcock, President of the Chicago Shipbuilding Co. This paper is abstracted elsewhere in this issue.

Mr. T. F. Newman said he had used pneumatic percussion riveters in connection with the construction of vessels for the revenue marine service, and the government inspectors passed such work readily. Where it was necessary to mill rivets, as in the case of shell riveting, he had found the saving only about 25%.

Mr. John Platt called attention to the methods of hydraulic riveting used in England, and remarked that he was surprised to find people still using blows instead of steady pressure here. He thought that large rivets could not be driven by purcussion riveters. The Holland & Wolff works use an immense crane which spans the vessel. Pendant from this crane are six 40 to 50-ton riveters, which are used to rivet framing, etc. In England and Ireland hydraulic riveters are extensively employed. To prevent freezing crude glycerine was used in proportions of ⅓ glycerine to ⅔ water. He had no doubt, however, but that for small work percussion riveting was satisfactory.

Mr. Tawresey believed percussion riveters could do all sorts of riveting in a rapid and satisfactory manner. The noise was, of course, disagreeable and had a bad effect on all concerned, possibly increasing costs slightly.

Mr. L. R. Pomeroy asked what were the limitations of percussion riveting. He knew several locomotive builders had tried pneumatic riveters and had later given them up because they could not get steam tight joints with them.

Mr. Babcock, in answering the various statements and questions, said that he had closed 1-in. rivets, but he knew of several cases where rivets up to 1¼ ins. had been set with the same style of hammer that he used. This need not be the limit, however, as it was simply a question of sizes of hammers. The air-pressure at the end of the hose should not be less than 100 lbs., and they were now putting in machinery which would give 125 lbs. He preferred pneumatic to hydraulic riveting, because of its simplicity and general applicability. The Harlan & Wolff traveling crane is very heavy, and only of use for only certain kinds of work. He admitted that the noise of percussion riveters was objectionable, but said that there was practically no limit to their use, it being almost as easy to operate a 10-ft. gap as a 4-ft. one.

In one vessel recently riveted up by hand 51,306 shell rivets were used, each costing 3.99 cts. In another instance 74,493 shell rivets were placed by the percussion riveter, mounted upon the frame described in the paper, and cost 2.96 cts. per rivet. In response to a question, he stated that as far as he could see there was no reason why long rivets could not be driven in this way.

Afternoon Session.

Immediately after calling the meeting to order, the President introduced Capt. Wm. H. Jaques, who presented a series of stereopticon views of foreign submarine boats, and the American boat "Holland."

The regular programme was resumed by Secretary Bowles reading a paper by G. W. Dickie, entitled, "Torpedo Boat Destroyers for Sea Service, with Special Reference to the Conditions that Prevail on the Pacific." In this the author said:

> A torpedo-boat destroyer must possess other qualities than those necessary for the destruction of torpedo boats. The destroyer must be a sea-going vessel, able to remain at sea with the fleet to which she is attached or to make independent voyages.
>
> The work of the torpedo-boat destroyer is to prevent the torpedo-boat attack, and is, therefore, performed in open water. She must keep the sea with the attacking fleet, watching every place of refuge for a torpedo-boat. She must, therefore, possess speed equal to that of the torpedo boat; a battery powerful enough to destroy her; sea-going qualities to enable her to keep a watch in spite of weather. She should be able to cover long distances at a high rate of speed and in stormy weather. The fleet to which she is attached should not be delayed and hampered by guarding her from harm; she ought, instead, to be able in all kinds of weather to act as a scout in advance of the fleet, keeping tho larger vessels informed as to the whereabouts of a possible enemy. Such would be an ideal torpedo-boat destroyer.
>
> It cannot be said that the present type of torpedo-boat destroyer comes near meeting these requirements. Quite a large number of destroyers now meet the requirements in the matter of speed, if required for a short time only, in smooth water, and if she is in good order; but the one quality of speed has been made paramount to all other qualities to such an extent that the full speed can only be reached when the conditions are such that the sea-going qualities can be neglected.
>
> The great distance between harbors on the Pacific Coast and the almost universal condition of rough water along the coast from Point Conception in the south to Cape Flattery on the north, with only one place of refuge, renders it necessary that any vessel for practical service outside the harbor of San Francisco or the smooth waters of Puget Sound must have good sea-going qualities and be able to remain outside in all conditions of weather.
>
> The qualities necessary for this service are not possessed in any degree by the present type of torpedo-boat destroyer. While they have made voyages of considerable length at sea, they have done so usually under the care of a larger vessel. They have needed extra care, both in watching the weather, taking advantage of every shelter that lies in the way.
>
> The 420-ton destroyers lately ordered by our government are a decided improvement in this class of vessel, but we do not think they are fitted even yet to meet the special conditions of service on the Pacific.
>
> The annexation of the Hawaiian Islands requires a much greater radius of action for such a vessel, and, we think, a different treatment. In fact, we maintain that if 30 knots or over is aimed at as the supreme speed, a sufficiently staunch sea-going vessel cannot be produced in the present state of the art, and that the present so-called 30-knot torpedo-boat destroyers have not, in fact, the speed with which they are credited as being available when required.
>
> If these boats and their machinery were made more substantial, so that their full power could be exerted at any time and without risk, and the hull stand a moderate sea without danger, the 30-knot boat, by reason of the extra displacement, would drop to about 27 knots; yet we venture to assert that such a boat, ordered to reach a point at sea, say 100 miles distant, in the shortest possible time, would reach the objective point in less time than the regulation 30-knot boat that is said to get a horse-power in 50 lbs. weight of machinery. A large proportion of naval vessels rated at high speeds, especially those over 20 knots, have obtained such speeds under conditions that cannot be reproduced when the speed is most needed, and a good, reliable, heavy-engined, 16- or 17-knot boat may outstrip them in a fight.

Mr. Dickie then outlined plans for a destroyer of 640 tons displacement and 7,000 I. HP. with a maximum speed of 25 knots and a sustained sea speed of 15 to 20 knots. He provided an armament of six 6-pdrs., two 4-in. rapid-fire guns and two submerged torpedo tubes aft of the engine room. He believed such a boat would show better speed under regular service conditions than any of the so-called 30-knot torpedo-boat destroyers, and for sea-worthiness, habitability, or fighting capacity would far outrank them.

The discussion of this paper was opened by Mr. Platt, who took exception to the use of the term "Torpedo-boat Destroyer." The craft described should properly be called a "Torpedo Cruiser." The boat outlined by the author possessed many desirable features, but he saw no reason for limiting the speed to such a low figure. He had been present at the test of an English destroyer of [illegible] tons, which had made 27 knots in a rough sea and against the wind or 32 with the wind. Such a boat would easily make 30 knots in moderate weather. Further, in English practice, it was customary to limit other matters, such as coal consumption, the maximum at present allowed being 2½ lbs. per horse-power.

In answer to a question by Mr. Stevenson Taylor, Mr. Platt stated that speed ratings were obtained, in the case of such boats, by averaging 6 runs over a measured mile between points. During these runs the turns of the screw were accurately determined, and thus data obtained from which the speed can be obtained at any time by knowing the turns of the screw.

In connection with this discussion the first topical question "The Utility of Torpedo Boats and Has the Submarine Boat a Place," was introduced, and Mr. Bowles read a letter from an officer who had commanded torpedo boats during the recent war. The opinion seemed to be that the torpedo boat was of great utility, but that a lack of drill and an insufficient complement of officers and men, accustomed to the handling of such boats, had made them of considerably less service than they might otherwise have been. The systematizing and standardizing of boats and equipment and the careful selection and drilling of the crews was strongly advocated.

Lieut. A. P. Niblack, in a letter, compared our torpedo boat system with the careful and complete methods of foreign countries, and regretted that the custom of hauling the boats out of the water was being adopted here.

A letter from Lieut.-Commander Kimball, who commanded the torpedo-boat division of the North Atlantic Station during the recent war advocated the submarine boat. He stated that if it be admitted that the torpedo is of use, then the submarine boat which is no more than a torpedo with a human mind directing its movements in place of the usual automatic devices, would be of far more service. If trenches and mines are useful or necessary on land, it was quite as essential to take advantage of the protection afforded by the water. The submarine boat is the only kind of inexpensive boat that can move up close to an enemy. Such a boat with a crew of five men could attack land batteries and enter harbors. It could make blockades ineffective, destroying mines, etc.

Capt. John Lowe spoke in favor of the submarine boat, and pointed out how much time, money and anxiety would have been saved had the United States had such a boat at Santiago. He believed that the future would see submarine despatch boats, gunboats, and observation boats.

Assistant Naval Constructor R. M. Watt, who had had charge of the repairs of the torpedo boats sent to the New York Navy Yard, considered the "Morris" the ideal type of torpedo boat, operating from a base. He favored only one type of torpedo boat, about 100 tons, and would then at once jump to vessels of 400 to 500 tons, building a vessel about as outlined in Mr. Dickie's paper for service as a scout or despatch boat. Mr. C. D. Mosher did not think the time had come for standardizing torpedo boats. The speed and power for a given displacement were yearly increasing, and we must have as high speeds as our enemy. Handling had a great deal to do with the poor showing of our boats. At present experiments were being conducted in England by Mr. Parsons, which, if successful, might revolutionize torpedo-boat construction.

Mr. J. G. Tawresey spoke as an unbeliever in torpedo boats. He admitted their moral effect, but based his views largely upon the fact that at present there were no indications that torpedo attacks would be successful. He would not be afraid of torpedo boats in the open sea. He was of the opinion that torpedo boats were entirely too light for any sort of sea service. Under special conditions they might be dangerous antagonists, but conditions must be taken just as they exist when the chance to fight occurs. So far, they had been used simply as dispatch boats and not with the best of success. They should not in any case be used for any other than the designed purpose.

Mr. F. L. Du Bosque favored the standardization of torpedo boats so that a man, when ordered from one to another, could at once perform his special duties properly. Water tube boilers on some torpedo boats had proven a success, and there was no inherent reason why all should not prove successful, if properly handled. The great trouble was that the boilers on a torpedo boat were used spasmodically.

Mr. John C. Kafer considered the construction of torpedo boats faulty. They never did what was expected of them, and the speeds credited to them were not reached in actual service. He did not favor any boat that could only keep up its speed from three to five minutes.

Mr. R. M. Watt called attention to the fact that in a torpedo-boat attack it was contemplated to have, say, half a dozen boats start from different directions. In the Battle of Manila two improvised torpedo boats started from 4,000 yds., and one of them succeeded in getting within 1,200 ft.

Mr. Stephenson Taylor considered the trouble due largely to the make up of the crews, most of them being men not familiar with the tools they were using. The "Scorpion," for instance, gave no trouble until taken by the government.

Mr. Bowles explained that the service of a yacht under ordinary conditions and the conditions imposed upon the converted yachts employed in Cuban waters was entirely different. Most of the vessels on the blockade were forced to use salt water at times in the boilers.

Mr. F. Meriam Wheeler then read a paper, entitled "Econmoy Test of a Unique Form of Feed Pump,' which will be abstracted in a later issue of Engineering News.

In discussing this paper Lieut. Walter M. McFarland, Engineer Corps, said that it must be remembered that the service of engines in the merchant marine and in naval vessels was entirely different. In the former they were started up and ran continuously for 6 or 7 days, while in the latter they might be started or stopped every five minutes. Hence it was that the converted vessels gave so much trouble. It was, therefore, necessary to have the various pumps separate from the main engines and leave the engines free to propel the vessel alone. Whatever form of pump was adopted must be designed with an idea of saving weight and economizing coal.

November 11.—Morning.

This session began with the reading of a paper, entitled "The Steam Yacht as a Naval Auxiliary," by Mr. W. P. Stephens.

> The work of reconstruction which has been under way in the United States Navy for the past 15 years has been limited almost entirely to the strictly fighting arm of the service—the battleships, cruisers and torpedo craft. Indispensable as they are, these of themselves do not constitute a perfect navy, in fact they are of comparatively little use without a large attendant fleet of auxiliary craft; transports, colliers, water boats, repair ships, supply ships, hospital ships, and small craft for various uses.
>
> The condition of the Navy at the outbreak of hostilities between the United States and Spain may be briefly summed up as strong in its personnel; comparatively strong

in fighting vessels, guns and armor; and absolutely unprovided with auxiliaries of all kinds. Of all the urgent work demanded both ashore and afloat, nothing was more immediate and pressing than the creation of an efficient fleet of auxiliaries.

The possibilities of the yacht fleet at the present time for conversion to war uses were, even from a theoretic standpoint, far from promising. Many of the vessels were ill-fitted in model for real service at sea; there was a lack of displacement for the added weights of armament and ammunition, of berthing space for crew, of bunker space, and suitable locations for magazines. The nominal speed, in many cases low in itself, was not realized even in smooth water, and in a sea there was a serious loss of the average working speed. There was no protection, no distilling apparatus; the capacity of the water tanks was generally inadequate, and the decks were not designed to withstand the shock of guns. The draught as a rule was greater than was necessary or desirable. The nature and extent of these defects were fully realized at the outset, but under the circumstances there was no other course but to take the yachts as they were and to make the best of them. All things considered, they have done their work quite as well as was to be expected; they have served a certain necessary purpose, and they were capable of doing even more had it been required of them. The work of the yachts, their success and failures taken together, with the work of other small craft, such as tugs, lighthouse tenders, etc., impressed into the same service, seems to indicate the desirability of the creation of a new type of small auxiliary not at present recognized on the Navy List. The speed may be placed at not over 18 knots. This, however, is not to be measured by the conventional yacht standard by which an 18-knot steam yacht takes the wash of a good 12-knot tug, but means a reasonable approach to the designed speed under ordinary service conditions at sea, and the ability to keep with the fleet even in bad weather. The model should possess seagoing qualities of the highest class; the draught should be limited to 11 or even 10 ft., as a maximum; the construction should be durable, with ample scantling both to carry the armament and to insure a long life with ordinary care in laying up; the engines should be strong and reliable, the bunker space as large as possible, and, as deck and side protection will probably be impracticable, especial attention should be given to the water-line protection of machinery and magazines through their location and the disposition of the bunkers.

The intended uses of this class call for three sizes: for sea work, as despatch boats and tenders, and for picket duty, vessels of not over 800 tons displacement. The next size to be of about 400 tons displacement. The third size, for harbor patrol service, to be of about 200 tons. A speed of 15 knots would suffice for this service, but they should be capable of towing a vessel out of possible danger.

In the discussion, Capt. Jacob W. Miller said: Although we were fighting a nation in the late war which did not make a second line of defense necessary, the yachts did not meet the conditions required. The yachts were purchased at maximum prices, and we could have got boats better fitted for the work if the same money had been expended some years ago. Yet the pick of the yachts in the United States were taken. None of the yachts could do over 10 knots continuously for 24 hours. There was not sufficient breathing space for the crew on converted yachts, and they were not rough and ready enough. Boats for harbor work must be strong enough to permit running up alongside of sailing vessels that are drifting in mine fields. Converted yachts were serviceable in very few particulars. He did not favor three types of such vessels, and considered two quite sufficient, one for inner patrol work, and one for outer.

Mr. J. G. Tawresey, who was a member of the Auxiliary Cruiser Board, said: The orders given to the Board was to select vessels that would act as "eyes to the fleet." We had to take such vessels as were available. As fighters they were makeshifts, filled with objectionable features. For one thing, they were tinder boxes. I want to emphasize the fact that we cannot improvise a navy from yachts and tugs. There was a very useful field for such a boat as suggested by the author, and the design presented would, he thought, quite fill the want.

Mr. John Platt called attention to the fact that no fast gunboats had been built in this country. A speed of only 18 knots for a vessel of 850 tons was very low, as it was quite possible to get 22 knots. The British Government had built a large number of torpedo gunboats with speeds ranging from 18 to 22 knots.

Mr. Bowles felt that there was a decided need of such a boat as was described in the paper, but a speed of 16 knots, provided it could be kept up, was sufficient. Referring to the lack of crew space on the converted yachts, Mr. Bowles said that as all the naval militia wanted to see service, the boats were often over-crewed. He favored only one size of boat, because experience had shown that the wrong size was always around when an emergency arose.

Lieut. W. P. White considered the inshore patrol or mine-field protection to be a function of such sea-going tugs as the government could impress, and it was out of the question to maintain a fleet of small boats for this purpose. The armoring of scout boats to any extent was inadvisable. In time of peace the various vessels should carry more than their war complement, so that in emergencies the extra men could at once man auxiliary or new vessels. The manning of vessels with entire naval militia crews was, he thought, poor policy, and it was far better to send them out as part of the regular crew of vessels in service. Battleships were of the first importance, and hence money should first be put into their construction, leaving despatch boats, etc., until later.

Mr. W. P. Stephens, in closing the discussion, said he did not mean to insist upon three classes. There might only be two classes, the larger being represented by the boat designed by Mr. Dickie. Lower speeds should be used and engines and other apparatus employed which could be successfully operated by inexperienced men.

In the absence of Chief Constructor Philip Hichborn, the Secretary read the opening paragraph of his paper on "Designs of the New Vessels for the U. S. Navy." That portion of the paper pertaining to the new battleships is given elsewhere in this issue. In speaking of monitors, torpedo boats, etc., Mr. Hichborn said:

> Since our last meeting, practically every type of vessel the government possesses has been put to the test in engagements with the enemy. There is no record, so far as I know, of the failure of any vessel to fulfil all expectations. The wonderful success attending these naval engagements has impressed the country at large with the value of, and the necessity for, an efficient Navy. Congress responded to this sentiment promptly and liberally, and within the past 6 weeks contracts have been made for 3 additional battleships, 4 coast-defence monitors, 16 torpedo-boat destroyers, and 12 torpedo boats. A full ship-rigged sailing vessel was also authorized as a practice ship for the Naval Academy, and is already under way.
>
> Monitors.—In appropriating for four coast-defence monitors, Congress did not contemplate providing vessels equal in size to the double-turreted monitors now in commission, the cost of hull and machinery being limited to $1,250,000.
>
> The bill provided that the vessels should have either one or two turrets, and it was found advisable to develop the design on the basis of a single turret mounting a pair of 12-in. guns. The trial speed is specified as 12 knots.

The paper then briefly outlined some of the important features of this type of monitor, but the information given is now of little value since within the last few days the Department has decided to use double turreted monitors carrying four 10-in. guns.

> Torpedo Boats and Destroyers.—The portion of the appropriation bill providing for these vessels authorized the construction of "16 torpedo-boat destroyers of about 400 tons displacement," and of "12 torpedo boats of about 150 tons displacement," all to have "the highest practicable speed." The designs prepared in the Department for the destroyers cannot be referred to any particular type. The midship section approximates to the oval form largely adopted by the French. The sections toward the stern are original, though resembling somewhat the form given by Thorneycroft to his twin rudder boats of some years ago. In addition to coal abreast the machinery, there will be the protection of 12½-lb. nickel-steel plate over a portion of the deck and on the sheer strake. The forward conning tower is of ½-in. nickel-steel plates. The vessels carry a battery of two 12-lb. and five 6-lb. guns, with two long torpedo tubes, mounted on the midship line.
>
> In both the torpedo boats and destroyers, the wood has been required to be fire-proofed and its use reduced to a minimum. The vessels will be lighted throughout by electricity and fitted with searchlights. Special attention will be paid to adequate ventilation, and every comfort and convenience consistent with the type will be supplied.

The Secretary suggested that the question of the utility of monitors be discussed in connection with the discussion on the paper just read.

Capt. William C. Wise said:

> It is my belief that the "Puritan" is the finest fighting ship in the United States Navy to-day. She could battle with a whole fleet. With 20 "Puritans" we could defend the whole coast.

Prof. Cecil H. Peabody discussed briefly the disposition of armor on monitors and battleships. He did not favor standardization of battleships and torpedo-boats beyond those built at any one time, since standards at times interfered with progress.

Col. E. A. Stevens asked if the conditions during the battle of Santiago were normal enough to permit the records of hits given the Spanish vessels being used for future design. If so, it would seem that such heavy armor was unnecessary for the large shells did not seem to hit.

Afternoon Session.

At the afternoon session the first paper presented was "Methods of Securing Watertight Work," by Assistant Naval Constructor H. G. Smith, U.S.N. The paper referred especially to ship construction, but as some portions of it are of general interest to all designers of riveted work, we shall abstract it in a future issue.

To facilitate discussion, since the general subjects were the same, the next paper, "Tests of the Strength of a Longitudinal Bulkhead Separating Two Engine Rooms," was then read by its author, Naval Constructor J. J. Woodward, U.S.N. This paper is abstracted on another page of this issue.

In discussing the papers, Naval Constructor J. G. Tawresey said that there should only be one kind of bulkhead—a strong and absolutely water-tight one. Historically there might have been two classes, the tight and the leaky, but in the future only the tight should be accepted. It must not be understood that the navy alone found leaks, for they were just as troublesome in the merchant marine. He considered that a good deal of the blame for leaky bulkheads could be laid to the draftsmen.

Professor Peabody considered the experiments described in the papers just read, as very important. He thought the Navy Department should conduct a series of experiments and put the data obtained in form so that it could be used for future design.

Mr. T. F. Newman saw no reason why bulkheads and ship's bottoms could not be made absolutely tight. On the Great Lakes they managed to secure such tight work that in many instances where the outer plating of the double bottom of vessels carrying grain had been injured, not more than 30 or 40 bushels of grain would be damaged, owing to the tight inner bottom

Mr. John C. Kafer thought that bulkheads were made to keep out the bulk of the water, and except in tank steamers, there was no need of builders going to great trouble to stop every little leak, provided the bulkheads were strong enough to stand the strain.

Col. E. A. Stevens asked what conditions were imposed in the United States service. In the British service he understood that the stiffeners must be strong enough to stand all strains without depending upon the sheeting.

In reply Mr. R. M. Watt read a letter showing how the stiffeners and bulkheads were calculated for the "Texas," and a comparison of the bulkheads of a number of United States vessels.

Mr. Bowles objected to placing 50% of the blame for leaky bulkheads upon the draftsman. The trouble was that after a bulkhead was made tight it was drilled full of holes by the machinists and electricians.

Mr. J. J. Woodward objected to any plan of bulkhead bracing that would weaken the protective deck, and said that where there was a conflict between the fighting strength of a vessel and a small amount of leakage, the latter should be disregarded. In response to a question, Mr. Smith said that in the test of the double bottom of the "Brooklyn" the time and labor of five men was required constantly for 14 months.

Owing to the short time remaining, the paper of Mr. Walter A. Post, on "An Electrically Operated 150-Ton Revolving Derrick," was read by title only. This paper will be abstracted in a later issue of Engineering News.

The last paper of the meeting, "Stability of a Battleship Under Damaged Conditions," was read by its author, Prof. C. H. Peabody. This was a report of a series of tests made with a small wooden model representing a battleship with its superstructure removed. The model, with inclining apparatus in place, was ballasted so that it floated at the proper water line, and so that it had the proper metacentric height. Then blocks, representing the parts or compartments laid open to the sea, were cut out and lead weights were fastened in place to compensate for the wood removed. Then various measurements were made to determine the initial stability and the stability at various angles of heel. The facts developed were illustrated by a series of diagrams, and a number of curves. Discussing the paper, Mr. Woodward suggested that in an actual battleship the superstructure could be made to assist in keeping the vessel afloat. Professor Peabody considered that the many openings in the superstructure would prevent its adding to the buoyancy of the vessel, should it start to capsize.

The discussion of the following topics was then taken up:

> First.—Under the circumstances of the blockade at Santiago, which was the more economical method of maintaining the boilers in readiness for immediate action—banking the fires or keeping them spread but very thin?
>
> Second.—Can you give any data as to the cost in coal of maintaining the engines and boilers in readiness for immediate service?

Mr. John C. Kafer read a letter from Chief Engineer Milligan, of the "Oregon," which stated that the fires on the "Oregon" were spread thin. There being from 24 to 27 tons of coal burned per day. The "Iowa" used banked fires. Mr. Kafer considered banked fires more economical, but not so advantageous for quick steam making, as keeping them spread.

Lieut. Walter M. McFarland presented some figures showing the coal consumption on the "Indiana," "Massachusetts," "Oregon," and "Iowa." These were in part:

	Tons.		Lbs.	
"Indiana"......	34.7	per day. or	7.21	per sq.ft. grate per hr.
"Iowa"........	35.16	" "	5.2	" "
"Massachusetts"	29.4	" "	6.5	" "
"Oregon".......	24.91	" "	4.35	" "

Note.—The "Iowa," "Massachusetts," and "Oregon" had spread fires.

This was, therefore, an indication that spread fires were also more economical, and there could be no question about the enormous tactical advantage.

Mr. Lewis Nixon presented a resolution to the effect that papers be invited on the subject of "Life Saving at Sea" and that two such papers be selected and printed in next year's "Proceedings." Motions thanking the various officers were passed, after which the final adjournment was taken.

In the evening fully 200 members and guests assembled at Delmonico's to participate in the annual banquet, which proved quite as successful as the business meetings had been. President Clement A. Griscom acted as toastmaster and the following is the list of toasts:

"The President of the United States;" "Our Navy; It Has Justified Its Existence and Glorified the Nation," Harvey D. Goulder; "Our Commercial Marine, Its Development and Extension is a National Necessity," Hon. George F. Edmunds; "The Naval Militia," Capt. J. W. Miller; "Naval Architecture," Lewis Nixon; "Marine Architecture," Lieut. Walter M. McFarland; "Our Manufacturers," Theo. C. Search. Personal toasts were: Charles H. Haswell, Charles Ward, William H. Webb.

On Saturday the members of the society enjoyed an excursion to South Bethlehem, Pa., through the courtesy of the Bethlehem Iron Co. The party, to the number of about 100, boarded two special cars provided by the Bethlehem Company, and attached to the regular Lehigh Valley Express, which left Jersey City at 8.20 Saturday morning. Immediately upon arriving at South Bethlehem the special cars were run into the yard of the Bethlehem Iron Works, and the entire party was transferred to a train of flat cars provided with seats. On this observation train the inspection of the works was made.

Starting at one end of the property, which is just one mile long, the party was taken past the scrap pile, where waste pieces of armor plate, stubs of ingots, etc., are stored for possible future use, into the forge shop, a building about 1,900 ft. long. In the main portion of this great building is a 5,000-ton Whitworth hydraulic forge, which was at work upon a steel jacket for a 12-in. coast defense gun. The wonderful power of this press, its quiet operation, the accuracy of its work and the skill with which its many movements were controlled by the few operators, was a revelation to many present.

Further on the powerful pumps necessary to give the 2,250 lbs. per sq. in. needed for the press were seen. A smaller press, 1,300 tons, but of the same type, was also in operation cutting off the end of a good-sized ingot. Continuing, the observation train and party passed the line of open-hearth furnaces, with capacities of 30 to 50 tons, and came to a halt beside the ingot casting pit, where the fluid compressed ingots, for gun forgings, engine shafts and the like, are made. This consisted of a pit about 20 ft. deep, in the center of which stands a 9,000-ton vertical hydraulic press. Fortunately for the visitors, an ingot was just being cast, so the whole operation could be seen by all. At one side of the great press stood a cylindrical flask built up of heavy cast-steel sections, bolted together and lined with refractory material. Over this a ladle holding about 15 tons of molten steel was run and the vent in its bottom opened, allowing a jet of liquid steel about 2 ins. in diameter to flow out and gradually fill up the vertical flask. When sufficiently filled, the flask, with its liquid steel contents, was slid over and centered under the hydraulic press and the pressure of 9,000 tons was gradually applied. Under the influence of this pressure, which is allowed to remain for six hours, the metal is compressed and the possibility of injury by air or gas bubbles is largely removed.

The next shop visited was the machine shop, where gun work was in progress. This building is 1,400 ft. long, and is filled with enormous planers, boring mills and other heavy machinery, most of which was engaged upon disappearing gun carriages for coast defense guns, and upon large size guns and mortars and a variety of engine shafts.

In another shop, devoted to armor plate work, the party was fortunate enough to see the great 13,000-ton press forging an armor plate. In this shop also the immense 125-ton steam hammer, now abandoned, stands as a monument to past methods and modern improvements.

Next the visitors were conducted to the department where common plates are Harveyized. A steel plate about 8 × 10 ft., intended for a large vault, was withdrawn from the furnace and placed over a large vat. A system of perforated pipes was swung over the plate, and when the proper temperature was reached water was turned on. In summer it is necessary to use ice water to ensure a proper chill, but at this season of the year ordinary river water is suitable.

The next move was to the tempering building, where engine shafts, gun tubes and long or thin pieces likely to bend and temper unevenly in a horizontal position are supported vertically in a gas blast furnace. The party arrived just in time to see a jacket for a 12-in. gun lifted from the heater, shifted over and rapidly lowered into a large cylindrical tank of oil, where it was to remain for from 5 to 6 hours. As the red-hot tube, fully 20 ins. in diameter and 20 ft. long, dropped into the oil there was next to no flame, and when once immersed only a small amount of smoke escaped from the oil surface.

In the armor plate trimming shop, the next one inspected, great slabs of steel armor, some flat and others curved, were having their edges beveled or squared up in planing machines. Such plates as had been hardened could only be planed down to the hardened surface, and emery wheels, either automatic or mounted upon flexible shafts for hand use, were employed to finish the hard edges. Plates as yet unhardened were being sawed, the saws consisting of steel disks some 4 or 5 ft. in diameter, with a series of separate cutting tools mounted around their circumferences. These saws advanced at the rate of about 4 ins. per hour, a rather lively rate, considering the fact that they were sawing tough steel from 12 to 14 ins. thick.

By this time the calls of the inner man were heard, and those in charge piloted the party to the office, where things to eat and drink were served and disposed of without stint, not, however, being served on armor plate. After a full inspection and realization of this department the special cars were again boarded and a quick return was made to New York, where the party disbanded, after a most instructive and delightful day.

BOOK REVIEWS.

Note:—In the review of the new edition of Johnson's "Engineering Contracts and Specifications" in our last issue the price of the book was, by an error, printed as $3.50. It should have been $3.00, which is a reduction of $1 from the price at which the first edition was sold.

COMMERCIAL RELATIONS OF THE UNITED STATES WITH FOREIGN COUNTRIES DURING THE YEARS 1896 AND 1897.—In two volumes. Vol. I. issued from the Bureau of Foreign Commerce, Department of State, Washington. Cloth; 9 × 5¾ ins.; pp. 1,283.

The introduction of this book proposes to show that the "International isolation" of the United States, so far as industry and commerce are concerned, is made a thing of the past by the logic of the change in economic conditions. We are now a competitor in the world-wide struggle for trade, and can no longer afford to disregard international rivalries. The report then commences the detailed review of the world's commerce, based upon data chiefly obtained from our consular agents. This volume deals with Europe, Africa, America, Asia, Australasia and Polynesia. The report covers character and amount of exports and imports, finances, trade conditions, transportation systems in many cases, and a vast mount of information useful to the American exporter.

CALCUL DES CONDUITES D'EAU.—Par Georges Davies, Conducteur au service des Eaux de Paris, Licencie es-sciences. Encyclopedie Scientifique des Aide-Memoire. Paris: Gauthier-Villars & Sons. Paper; 7½ × 4½ ins.; pp. 194; illustrated. Paper, 2.50 francs; boards, 3 francs.

The author commences his work by a discussion of the theory of the flow of water in pipes or conduits, under different conditions; gives the formulas of Prony and Darcy and recommends the employment of the latter under the conditions stated; he also notes the formulas of Weisbach, Ganguillet and Kutter, M. A. Franck, Manning, Unwin and Lampe. Succeeding chapters discuss conduits with reservoirs, variable diameters, distribution from various points on the pipe line, and miscellaneous questions arising in the supply and control of water in pipes. His final chapter treats of the study of distribution systems, arrangement of pipes, discharge, diameters and loss of head, syphons, etc. He closes with a number of tables of coefficient velocities, discharge, etc., as deduced from Darcy, Maurice Levy and Flamant. The work is chiefly theoretical and mathematical, with a few actual examples noted. The author does not enter into the details of practice in the form of pipes, valves and general appliances in pipe distribution.

STREET RAILWAY ROADBED. By Mason D. Pratt, Assoc. M. Am. Soc. C. E., and C. A. Alden, Assoc. M. Am. Soc. C. E. Street Railway Publishing Co., New York. Cloth, 6 × 9 ins.; pp. 135; 157 illustrations; $2.

As stated in the preface, the subject matter of this book is largely made up from contributions of the authors to the "Street Railway Journal," "Engineering News" and the Proceedings of the Am. Soc. C. E. About one-third of the book is given up to a historical review and a consideration of what governs the shape of rails. In this portion are some 50 line cuts representing sections of rails and angle plates showing the gradual increase in web depth and the changes of form of head and base. There are also about 30 cuts under the title of "What Governs the Shape of Rails," and the T-rail as adapted to street railways is also considered. This is followed by a discussion of track fastenings and joints, curves, special work and guard rails. The remainder of the volume is devoted to a discussion of the advantages of spiral curves, in connection with which is given a series of tables and formulas and remarks on the design of special work. The last chapter consists of a set of skeleton specifications for street railway tracks.

Considering the book as a whole we feel compelled to criticise it in several points. For instance, in the chapter on joints, cast joints and electric welded joints are barely touched upon, while "bonding," a very important matter where electric roads are concerned, is not even mentioned. We find no mention either of the recent practice of laying rails directly upon longitudinal concrete footings and discarding the use of ties. Aside from several such defects the information contained under the various headings mentioned will doubtless be of considerable assistance to those having to design or construct street railways. The principal value of the book rests in the chapters on curves and the design of special work.

THE METRIC SYSTEM OF WEIGHTS AND MEASURES, issued by the Hartford Steam Boiler Inspection and Insurance Co., Hartford, Conn. Leather; 6 × 3¾ ins.; pp. 196. $1.25.

Of the many metric conversion tables issued, this is by far the best and most convenient that has ever come to our notice. The actual work of calculating the tables and reading the proof has been done by Mr. A. D. Risteen, Associate Editor of "The Locomotive" and late of the computing division of the U. S. Coast and Geodetic Survey. This in itself is a guarantee of the care and accuracy with which the task has been performed. The history of the meter is given in full, together with a general discussion of the units derived from the meter. Then follows a table of metric units, the U. S. equivalent and the logarithm to be applied in working from this data. A full list of the tables inserted in this handbook is as follows: The units reaching 100 in each case and two tables being given under each head from metric to U. S. standards and from U. S. to metric; centimeters to inches; meters to feet; meters to yards; kilometers to miles; square centimeters to square inches; square meters to square feet; square meters to square yards; square kilometers to square miles; hectares to acres; cubic centimeters to cubic inches; cubic meters to cubic feet; cubic meters to cubic yards; cubic kilometers to cubic miles; cubic centimeters to U. S. fluid ounces; liters to U. S. liquid quarts; liters to U. S. gallons; liters to British liquid quarts; liters to British gallons; liters to U. S. dry quarts; cubic meters (steres) to U. S. bushel; grammes to grains; grammes to avoirdupois pounds; kilograms to avoirdupois pounds; grammes to troy ounces; kilograms to troy pounds; milliers to short tons; kilograms per square meter to pounds per square foot; kilograms per square centimeter to pounds per square inch; kilogram-meters to foot-pounds; calories to British heat units; calories to foot pounds; force de chevaux to horse-power; grammes in a cubic centimeter to ounces in a cubic inch; kilograms in a cubic meter to pounds in a cubic foot; milliers in a cubic meter to short tons in a cubic yard, milligrams in a liter to grains in a U. S. gallon; comparison of Centigrade and Fahrenheit thermometers. This list, better than a page of comments, conveys an idea of the useful range and application of the tables. The equivalents in both metric and U. S. measurements, are carried out to three places of decimals in the regular tables, and to six, or even eight places, in the special table of metric equivalents. Though the tabular numbers run only to 100 the equivalents of any number can be readily obtained, as explained in the chapter on "The Use of the Tables." The great usefulness of this little book has already been proven in the short time it has been in this office.

THE HEAT EFFICIENCY OF STEAM BOILERS; Land, Marine, and Locomotive. With Tests and Experiments on Different Types, Heating Value of Fuels, Analyses of Gases, Evaporation and Suggestions for Testing Boilers. By Bryan Donkin, M. Inst. C. E. With numerous tables, plates and illustrations. London: Charles Griffin & Co., Ltd. Philadelphia: J. Lippincott Co. Cloth; 8vo.; pp. 311.

The author of this book says in his preface that he has had frequent opportunity during the last 25 years of making tests on steam boilers, and that as his tables of results increased it might prove useful as a collection of facts, if thrown into the shape of a book. To his own tests he has added those of many other experimenters, and he has thus "thrown" together in tabular form the figures of no less that 425 experiments in English and other boilers. We quote the following from the preface:

> It is mainly by collating and comparing a large number of reliable tests, that the principles governing combustion and efficiency in different types of boilers can be determined. The author hopes, therefore, that his contribution to the heat question, by breaking comparatively new ground, will lead the way, and incite others to make more complete collections of careful boiler experiments, the only mode in which the subject can be thoroughly and practically studied.

We hope that Mr. Donkin's book will "incite others" to do nothing of the kind, and that his "collection" will remain for many years to come the most extensive collection in existence. It is one thing to have a mania for making collections and quite another to have the faculty of studying the collection after it is made. Mr. Donkin is a good collector and tabulator, but his study of the collection, as far as we can judge from the book, is meager and unimportant. The tables occupy 100 pages; the chapter on discussion of the trials and conclusions only six. The most important conclusion drawn is the following:

> The efficiencies vary, even in the same type of boiler, owing to very different working conditions. Thus in Cornish, externally fired, they ranged from almost the highest, 81.7% to 53%. Again, Lancashire, internally fired, show, under favorable conditions, an efficiency of nearly 80%, while they also give the lowest, viz., 42%.

This conclusion is important but it is not at all new, for the author quotes from Mr. Barrus's book on "Boiler Tests," published in this country several years ago a practically identical conclusion as follows:

> The general conclusion as to economy of different types of boilers depends much more upon their proportions and upon the conditions under which they work than upon their type With suitable proportions and favorable conditions the various types give substantially the same economic results.

An interesting statement concerning air supply to the coal on the grate is as follows:

> The only right method of testing the efficiency of a given grate with a given coal and draught is to analyze the gases of combustion and thus to ascertain the percentage of air in excess or the reverse. If too much has been admitted to the grate the bars should be arranged nearer together; if too little they should be spaced out further apart.

We venture to say that there is not a boiler user in Great Britain who is likely to follow Mr. Donkin's advice in this particular and that Mr. Donkin himself would not follow it if he were in charge of a boiler. What he or any one else would be most likely to do, if his analysis of the gases showed that too much air was passing through the fire, would be to increase the thickness of the bed of coal on the grates, and to take extra care that there were no "air-holes" in the fire.

Besides the tables of tests and the very brief statement of conclusions drawn from them the book contains a fair compilation of information on classification of types of boilers, on fire grates, on mechanical stokers, on feed water brakes, superheaters, feed pumps, etc.; discussions on combustion, on the transmission of heat through boiler plates, on smoke prevention; descriptions of testing apparatus; notes for making boiler tests, etc. An appendix contains illustrations of all the principal forms of ancient and modern boilers. On the whole the book is a valuable collection of interesting facts concerning steam boilers, although it is far from being as good a treatise on steam boiler efficiency as we should expect from the author.

THE TWO LARGEST VESSELS yet designed for the ore trade on the Lakes have just been contracted for by the Bessemer Steamship Co. The first is a steamer, to be built by the Globe Iron Works Co., of Cleveland, O., 475 ft. long, and 50 ft. beam, with quadruple expansion engines. The second is a barge, 460 ft. long, 50 ft. wide and 30 ft. deep, to carry 7,500 tons on 17½ ft. draft, to be built by the American Steel Barge Co., Superior, Wis.

◆

THE LARGEST ORDER FOR WATER-TUBE BOILERS ever given in this country, so far as we are aware, is that which the Cramp Co., Philadelphia, has just given to the Stirling Co., of Chicago, for the water-tube marine boilers for Russian war vessels, now under construction at the Cramp yards, amounting to about 35,000 HP.

◆

THE REDUCTION IN THE COST of producing iron and steel in the United States, since 1880, is commented upon by the English "Iron and Coal Trade Review." According to that journal, the labor cost of producing crucible steel, in 1860-'65, was about $75 per ton, and is now not over $2.40. Between 1880 and 1890, the labor cost of producing a ton of pig-iron was more than twice what it is now, broadly speaking. The raw material also costs less. Lake Superior ores, at Pittsburg, have fallen from $8.40 to $3.60 per ton in comparatively recent times, and coke, at Chicago, has fallen from $7.20 to $2.88 and $3.60 per ton. The wages cost of producing a ton of pig iron, at Pittsburg, less than 25 years ago, was fully $4.80; to-day it costs from 48 to 72 cts. in the best managed works. Twenty years ago mine owners wanted $2.40 a ton profit on ore, for the highest grades; to-day they will accept less than 24 cts; and the same decrease in profits demanded applies to the pig iron maker, the coke manufacturer and the producer of finished products. The writer says that the success of the American iron and steel producers is due to their vigorous and persistent attention to business administration, in mining, manufacture and transportation.

◆

STANDARD STEEL BRIDGE PLANS FOR CHINA are being made by C. F. Loweth, M. Am. Soc. C. E., Chief Engineer of the Davenport & Rock Island Bridge, Railway & Terminal Co., of Davenport, Ia. The structures range from small plate girders to 200-ft. spans. They are being made for the Chinese Railway Administration.

◆

NEW YORK'S OCEAN TONNAGE, says the N. Y. "Journal of Commerce," is only exceeded by that of London. For the fiscal year 1898, the aggregate tonnage of vessels entering and declaring at New York was 15,337,142 tons; this is only approached by the year 1880, with a tonnage of 15,041,083 tons. The condition of the carrying trade, for 1898, is shown as follows, for entering vessels: 449 American sailing vessels, 231 686 tons; 282 American steamships, 720,553 tons; 787 foreign sailing vessels, 531,295 tons; 2,817 foreign steamships, 6,277,878 tons; total, entering, 4,335 vesels, carrying 7,761,412 tons. The vessels clearing from New York in the year numbered 4,727, in about the same proportions as above, and they carried 7,575,730 tons. As compared with English ports, for 1897, we find a total inward and outward movement of 15,797,659 tons for London, and 11,261,051 tons for Liverpool. In 1883 and 1892, however, New York surpassed London in the aggregate of tonnage.

◆

A TORPEDO-BOAT SPEED COURSE, one measured mile in length, has been located by the Navy Department on the Delaware River, below the mouth of Christiana Creek. All torpedo boats hereafter built on the Atlantic coast will be tested for speed over this measured mile; the course allows one mile more in which to get up speed and another mile in which to slow down.

◆

THE SPANISH CRUISER "REINA MERCEDES" was sunk in Santiago Bay by the Spaniards by opening the sea-valves, reports Lieut. Lucian Young, U. S. N. Her hull is otherwise in good condition, and is resting on the edge of the channel bank, with 110 ft. overhanging deep water. Lieut. Young thinks that by plugging the valves she could be pumped out and raised. The latest accounts indicate the final abandonment of the Spanish cruiser "Maria Teresa," raised at Santiago and wrecked on Cat Island on her way to Norfolk.

◆

THREE OF THE SPANISH SHIPS SUNK AT MANILA are to be raised by a Hong Kong firm of wreckers and put in thorough repair for $500,000, according to a contract just made by Admiral Dewey. These ships are large gunboats; two, the "Isla de Cuba" and the "Isla de Luzon," are 200 ft. long, 30 ft. beam and 11½ ft. draft, with a displacement of 1,040 tons each. They are built of steel, have twin screws, a good protective deck and a battery of six 4.7-in. Hontoria guns, four 6-pdrs, two 1-pdrs., two Nordenfeldt guns and three torpedo tubes. The speed is 15.8 knots under forced draft. The other, the "Don Juan de Austria," is 210 ft. long, 32 ft. beam, 12½ ft. draft and 1,152 tons displacement. She was built at Carthagena in 1887, and her armament includes four 4.7-in. Hontoria guns, four 6-pdrs., one machine gun and two torpedo tubes. These vessels are to be raised under the superintendence of Naval Constructor W. L. Capps, U. S. N.

◆

THE BUFFALO RIVER IMPROVEMENT, in Buffalo, N. Y., has reached the stage of completion of plans and specifications, which are now to be submitted to the Board of Public Works with a request for the issue of proposals. This work contemplates the widening, straightening and deepening of Buffalo River, between Hamburg St. and the east city line, and also of Cazenovia Creek, from its junction with the river to Cazenovia St. The plan for the river proposes a bottom width of 230 ft. to the creek, 150 ft. beyond the creek, and 120 ft. in Cazenovia Creek. The sides are to be diked 15 ft. above the normal water surface, and the estimated quantity of material to be moved is 3,000,000 cu. yds. The estimated cost of dredging is about $700,000. Five highway and six railway bridges, crossing these streams, will have to be altered. Bids may be advertised for shortly, though there may be some opposition from the railway companies affected.

◆

THE SEA-WALL AT CHICAGO, which was built to protect the Lake Shore drive, has been broken away by the waves of the recent severe storms on Lake Michigan, and a gap of about 80 ft. in width has been formed. The wall is of concrete, with a foundation of piling. There are two rows of piles, those of the front row being set close together, and those of the back row 4 ft. apart. The space between them was filled with bundles of brush, covered with rubble stone. A decking of several layers of plank on top of the piles forms the base for the concrete wall. The spaces between the piles in the front row were wide enough to allow of a steady wash of the water, disturbing the ground and allowing the brush and stone to settle and wash out. The horizontal and vertical action of the waves of a high sea soon breached the foundation and overturned the wall. This result appears to be due to the fact that the work, like other public works in Chicago, was not properly executed. The design originally prepared by Gen. Fitz Simons included a revetment at the toe of the wall, and a line of sheet piling in front of the revetment, thus preventing any wave action from reaching the foundations. The stone filled crib work of the bulkhead wall for the future Lake Front Park received little if any damage during the storms.

◆

DEFECTIVE SEWER WORK on the intercepting sewers in Chicago has been charged by a local paper, the principal charge being that some of the brick rings, especially in the invert, are laid without cement, and also that the work is done without properly draining or pumping out the trench, so that the invert is built in mud and water. The charges were insisted upon so strenuously, that Mr. McGann, Commissioner of Public Works, consented to have an inspection made by an engineer appointed by this newspapers. Gen. Sooy Smith, M. Am. Soc. C. E., accepted the appointment, and had openings cut in the walls of the North Side sewer. His report states that the materials and workmanship are good, except that at one or two points the middle ring of brick was laid without mortar or with a less quantity than the outer rings. He further stated that this lack of mortar in the middle ring "was a defect such as sometimes creeps into brickwork in sewer linings in spite of the best intentions and instructions of the contractors, and the vigilance of the inspectors in charge of the work." The newspaper which made the charges, however, now complains that the invert was not examined, that the inspection was not made at the points where it had reported bad work, and that none of its representatives were with the inspecting party.

◆

The MOST SERIOUS RAILWAY ACCIDENT of the week occurred Nov. 18, on the Pennsylvania R. R., just east of the Hackensack River, near Jersey City, N. J., and caused the deaths of 11 track laborers, and the injury of as many more. The gang was at work on the west-bound track and moved over to the east-bound track to let a train pass. The noise of the passing train prevented their hearing an approaching east-bound express, and the dense fog, which prevailed at the time, hid it from their sight.

◆

TWO FATAL ACCIDENTS, due to low hanging arc lights, recently occurred in Baltimore, Md., and have served to arouse the question of responsibility and whether the Police Board had authority to compel electric light companies to place arc lights at a safe distance above pavements. Mr. G. R. Gaithers, Counsel to the Board, states that:

> It is clear that whenever such lights are so placed as to endanger the lives of the persons who use the streets, such lights become a nuisance and should be removed, or the parties causing the nuisance punished. Anything which endangers the safety of persons lawfully passing over a highway is an obstruction and indictable as such.
>
> I am of the opinion that your honorable board should instruct the members of the force to notify any company having arc lights in a position which is dangerous to the public safety to remove them to a proper and safe position, and in the event of the failure of any company to do so, to lay the matter before the state's attorney with the evidence, so that an indictment may be found by the grand jury against the offending parties.

◆

A CONTRACT FOR 15,000 ELECTRICAL HORSE-power was closed on Nov. 21 between the Union Carbide Co. and the Niagara Falls Power Co., the power to be delivered some time next summer. This great block of power is the product of three of the big dynamos in the great Niagara central station. The existing works of the Carbide Co. will be continued, but in order to utilize the additional amount of power, immense new works will be constructed at once. The buildings will be located on the power company's lands near the trestle of the Niagara Junction Ry. and north of the Erie and Central tracks. One of the buildings will be two stories high and over 800 ft. long.

◆

PAYMENT FOR ALLEGED DAMAGE by electrolysis has been made by the Consolidated Street Railway Co. to the city of Atlanta, Ga. The amount was small, only $16.91, and was paid under protest in settlement of two bills presented by the city for damages to its water mains or services. The council passed an ordinance, not long ago, requiring all electrical companies in Atlanta to keep their currents off water and other pipes.

◆

IN REGARD TO INDUSTRIAL ENTERPRISES IN Cuba, Special Commissioner Robert P. Porter, reports to the President that little can be done until the sanitary conditions can be improved in all the industrial centers. For the commercial prosperity of Cuba, and for that of the Southern part of the United States as well, the germs of yellow fever, existing in all the larger Cuban towns, must be destroyed. Mr. Porter recommends the appointment of a commission of experts, including engineers of skill and experience, which shall make a sanitary survey of Havana and Matanzas, and report what can be done to stamp out yellow fever in these cities.

◆

PROGRESS ON THE TRANS-SIBERIAN RAILWAY is reported as follows by the London "Times": By the Russian-Chinese treaty of September, 1896, a large part of the old line to Vladivostock, by way of the Amour River, was abandoned, and a new line laid down from Stretensk across Eastern China, or Manchuria, directly to Vladivostock. But, as a consequence of the establishment of the Russians on the Gulf of Pe-chi-li, the terminus is now Port Arthur, and the latest route leaves the old line at Chi-Tai, about 300 miles from Lake Baikal and far west of Stretensk. The rails are now laid to Listvenitchoie, on the west bank of Lake Baikal; the large ice-breaking ferryboat, for taking trains across the lake to Masova, is under construction, and in the coming spring, the line around the lake will be commenced. East of Lake Baikal the rails are being laid at the rate of four miles per day. Train service with Europe commences at Irkoutsk; from this point west to Krasnoiarsk the line is being operated, but is not finished, and the Oka and Ienissei rivers are crossed in boats. West of Krosnoiarsk the line is in complete working order. The trip from Moscow to Lake Baikal, second-class, costs about $24 and occupies about 12 days; first-class carriages only go once a week as far as Tomsk, and ordinary trains go once a day to Krosnoiarsk, and three times a week to Irkoutsk. All cars, however, are provided with reclining chairs, for sleeping purposes.

TRIPLE-EXPANSION PUMPING ENGINE AT OGDENSBURG, N. Y.

By Charles A. Hague, M. Am. Soc. M. E.*

(With two-page plate.)

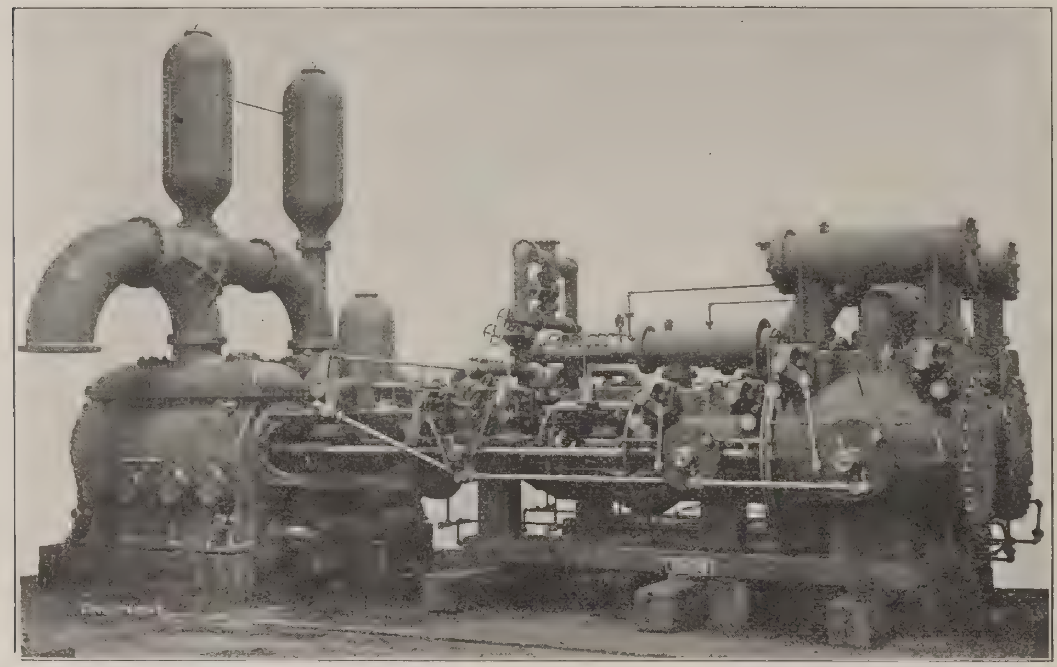

FIG. 1.—VIEW OF TRIPLE EXPANSION PUMPING ENGINE AT OGDENSBURG, N. Y.
The Snow Steam Pump Works, Buffalo, N. Y.

This engine, just installed by the Snow Steam Pump Works, of Buffalo, N. Y., in the pumping station of the Ogdensburg City water-works, represents the most advanced practice in the type technically known as low-duty triple expansion. The engine is of the horizontal condensing duplex direct-acting class, with a high, an intermediate, and a low pressure cylinder on each side of the machine, each set of cylinders operating a double-acting plunger contained within separate water cylinders; the water cylinders being connected to common suction and delivery pipes by means of cross pipes, in the usual manner.

Each high pressure cylinder has a diameter of 16 ins., intermediate, 23 ins., and low pressure, 40 ins. The pump plungers each have a diameter of 23¼ ins., the common stroke of all being 36 ins. The steam distributing valves are of the semi-rotative, or "Corliss" type, and are arranged as follows: At each end of the high pressure cylinder is a valve for the double purpose of admission and exhaust, while directly above each of these valves is placed an independent cut-off valve, thus reducing the clearance to a low percentage, and as the low piston speed permits of considerable restriction in the port area, the valves are made comparatively short, thereby eliminating to a great extent the corners formed by the spaces usually found in this form of steam valve, having ports of a length equal or nearly equal to the diameter of the cylinder, such as would, of course, be necessary at high piston speeds. At each end of the intermediate and low pressure cylinders are similar valves, with the exception of the cut-off valves, which are omitted on the latter two cylinders.

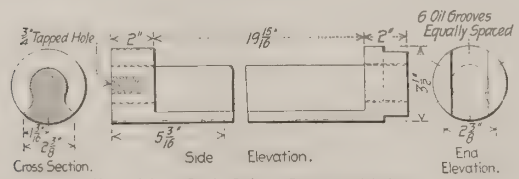

Fig. 11.—3 1-2-in. Steam Valve.

The point of cut-off in the high-pressure cylinder is determined by the ability of the engine to finish its stroke at the various speeds at which it may be running, the higher the speed the shorter the cut-off, and although in any event no very short cut-off can be obtained, still it is sufficiently early to produce an economy which well repays the addition of the two high-pressure cylinders to the ordinary type of compound condensing direct-acting engine, when the conditions of investment of capital forbid a much more costly type of compound engine. The theory of cut-off in this type of pumping engine seems to be that a certain percentage of the stroke at its terminal end may be cut off, regardless of the distance this point may be from the beginning of the stroke, and, therefore, the length of the stroke of the engine comes into play as an important factor in designing the best proportion of engine for any particular service, the arguments put forward by different makers failing to agree as to the length of stroke desirable, although there is little doubt that the number of strokes per minute is quite as prominent a factor of high efficiency as the feet traveled per minute. After being released from the high pressure cylinder the steam passes through reheating receivers to the intermediate cylinder, where it follows the piston full stroke; is again released, passes through a second reheating receiver and into the low pressure cylinder, where it also follows the piston throughout the stroke; is again released and goes to the condenser. The intermediate and low pressure cylinders are steam jacketed, the high pressure cylinder being without such protection.

The main valves of all the cylinders are driven from wrist plates, as in Corliss engines, the cut-off valves of the high pressure cylinder being operated by means of a pair of sliding blocks fitted to a sort of rocking "V," these blocks being capable of simultaneous adjustment by means of miter gears and a hand wheel, so as to vary the point of cut-off to suit the speed of the engine. The wrist plates which actuate the main valves are driven from rock shafts, these rock shafts being driven in turn, as is usual in the "duplex" machine, by having each side of the engine drive the main valves for the opposite side. The cut-off valves are driven from the same rock shafts, but so connected that each side of the engine operates its own cut-off valves. A feature worthy of note is the arrangement of the pins on the rock shaft arms from which the valve-gear is given motion, these pins being enlarged above the ordinary to an extent which permits of the driven rod passing directly through the body of the pin, thereby retaining all pressures directly in the center lines of force and entirely removing any tendency to bend or spring the rods.

The intermediate and low pressure steam cylinders are fitted with cushioning valves in the usual manner, but their use may be entirely obviated by the proper adjustment of the point of cut-off in the high pressure cylinders to suit the engine's speed, the cut-off valves being adjustable as a group or each individually, so that irregularities of strokes may be corrected at any single point without interfering otherwise with the operation of the engine.

In connecting the steam pistons, the high pressure and intermediate are attached to a single rod which extends through the forward head of the intermediate and the back head of the high pressure, then out through the front head of the high pressure; metallic packing being used in the stuffing boxes; the rod is then secured to the main cross-head, which rides upon a shoe running in a guide between the steam and water ends of the engine. The back head of the intermediate cylinder has no opening through it, and is removable into the low pressure cylinder, the intermediate and low being butted and secured together. The low pressure piston is attached to the main cross-head by means of long side rods passing out through the front head of the low pressure cylinder within the annular space defined by the difference in diameter between the low and intermediate cylinders, thence the rods pass forward until they reach the cross-head.

Another peculiar and rather commendable feature of the engine is found in the heavy cast-iron bed-plates extending under the entire steam ends; these bed-plates being solidly bolted to the foundations, and the cylinders permitted longitudinal movement upon the pedestals formed upon the bed-plates, so as to compensate for expansion and contraction; the water ends being securely bolted to the foundations.

The condensing apparatus consists of a jet condenser, with an independent single cylinder steam-driven air pump with a steam-thrown valve; a part of the overflow from the air pump is diverted into a small hot-well, and thence taken by an independent boiler feed pump and sent to the boiler; the exhaust from the steam ends of the air pump and the boiler feed being economically utilized through the medium of a feed water heater. The injection pipe leads from within the screenbox of the main suction pipe so that a sudden and undue drop in the water level in the well will rob the condenser of water and so break the vacuum before the main suction is in danger of losing its water. This is especially desirable for the reason that the river is at times heavily charged with water-soaked sawdust from mills above, which will at times completely obstruct the screens.

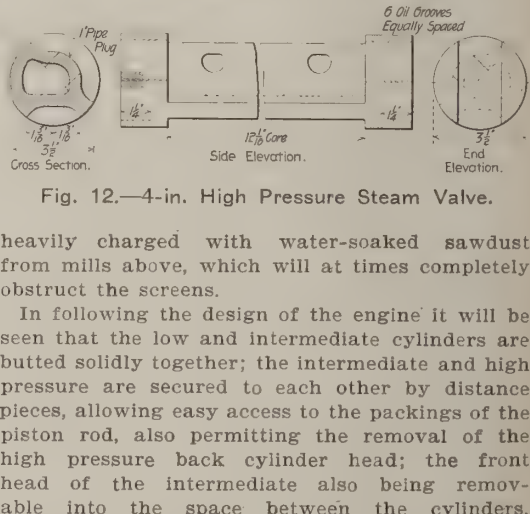

Fig. 12.—4-in. High Pressure Steam Valve.

In following the design of the engine it will be seen that the low and intermediate cylinders are butted solidly together; the intermediate and high pressure are secured to each other by distance pieces, allowing easy access to the packings of the piston rod, also permitting the removal of the high pressure back cylinder head; the front head of the intermediate also being removable into the space between the cylinders. In the arrangement of the pumps proper, the structural connection between the front end of the high pressure cylinders and the water end is by heavy cast-iron frames, these frames supporting the rock-shaft bearings, and also the cross-head guides, leaving convenient access to the various details.

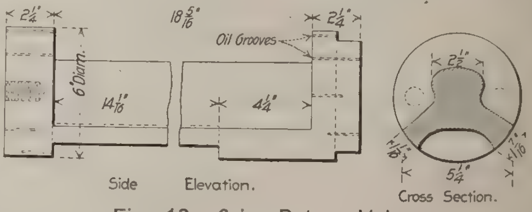

Fig. 13.—6-in. Rotary Valve.

The cross-head is of cast steel and is carried upon a bronze shoe, thus relieving the piston and plunger rods of all cross straining due to weight. It is made exceptionally heavy and strong, thereby affording ample strength and at the same time adding to the inertia of moving parts. The middle eye of the cross-head is of two sizes, one taking the high pressure piston rod and the other the main plunger rod; the outer eyes being provided for the low pressure rods.

---

*Consulting Engineer, 39 Cortlandt St., New York city.

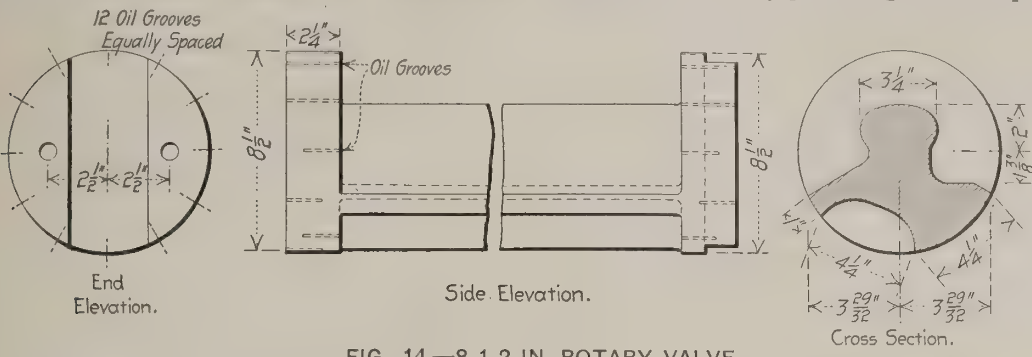

FIG. 14.—8 1-2-IN. ROTARY VALVE.

The water end consists of two separate pumps of the regular construction generally found in this class of work, but with liberal valve area permitting probably with the limited suction lift here found, a speed of 50% in excess of that called for in the contract. The pumps are heavy enough to carry 100 lbs. pressure continuously in case of fire. A special feature of the water end is the location of the cross suction pipe directly beneath the outer ends of the pumps, so as to reach the supply well without undue deflection, and also to make a clear and clean floor about the engine possible. In carrying out this feature, partly made necessary by the limited space lengthwise of the engine, the pumps are arranged to overhang the foundations nearly half their length, this overhang being met by the introduction of heavy I-beams which extend from the shortened foundation to a thick stone wall forming a part of the older and original building.

Some peculiar characteristics of the water of the Oswegatchie River in the shape of coarse sawdust, etc., make it desirable to use unusually efficient screens, and to let all surplus water flow by, the pumps only taking through the screens the actual quantity of water sent into the distribution, instead of attempting to screen all of the water entering the well. To effect this result, and at the same time afford ready access for removing and clearing the screens without interfering with the running of the engine, a special design of screen box with very liberal areas of screening surface is used, the passage of water through the meshes of the screens being at the rate of about 0.1 cu. ft. per second per square foot of screen, with the engine at full speed. It has been found by experiment that this rate of flow will not produce sufficient current to overcome the gravity of the water-soaked impedimenta, so that the worst that can happen would be a very slow accumulation of refuse at the bottom of the well, and provision is made to remove the most of this during the operation of the engine, by the use of a 12-in. "blow-out." The screens are of iron wire, ⅛-in. mesh.

In the main pumps, owing to the tannic acid qualities in the water, the plungers and rods are covered with brass, the pump sleeves through which the pump is worked are lined with brass, and all of the essential features of the pump valve outfit are also of brass.

The cross-delivery pipe is located midway of the length of the pumps, has easy curves, and joins the main delivery pipe at the left-hand side of the water end, this main pipe of 20-in. diameter being provided with a check valve opening downwards, and a gate valve just below the check, the pipe passing through the floor and out of the building through the basement wall. The hand wheel of the gate is within easy reach of the floor, and the entire arrangement apparently reaches the height of convenience and economy of space, the latter item having been held constantly in view on account of the environment.

The top speed is fixed by means of an automatic pump governor, so that it is impossible for the engine to "run away" by a sudden or considerable decrease of the water pressure. There has been no formal duty test made as yet, because of the reluctance of the city authorities to interfere with the engine in its regular service, during the refitting of the rest of the plant which is now going on, but the preliminary experiments indicate that 80,000,000 foot-pounds duty will be slightly exceeded, the guarantee under the contract being 75,000,000 per 1,000 lbs. of steam.

There is also being installed in this plant a pumping engine to be driven by water power, of unusually large size, possessing some special features to adapt it to the situation, embracing special arrangements for the admission and screening of the water, suction and delivery pipes, etc. This "power pump" is to be operated by two 48-in. turbine wheels, with the transmitting shafts fitted with friction clutches so as to meet the exigencies of domestic and fire services under "direct pressure" with promptness and certainty.

SPECIFICATIONS FOR STRUCTURAL STEEL AND RAILS.*

By Wm. R. Webster, M. Am. Inst. M. E.

The specifications for American structural steel and rails are, on the whole, very satisfactory. Some, of course, are behind the times; but common practice of to-day gives a much better material than they call for. On the other hand, there are specifications in which the physical and chemical requirements do not agree, or that call for an extremely high elastic limit or other results, which cannot be obtained by the ordinary methods of manufacture and testing. Specifications of this kind cause the manufacturers temporary trouble, but soon adjust themselves, either by the engineer coming out frankly and modifying them, or giving instructions modifying the point at issue, though still adhering to his printed specification. The latter method is much to be regretted, as the specifications are very misleading and the steel accepted under these modifications never has and never will meet the original requirements.

Our government specifications, at first, gave the manufacturers considerable trouble; but when they found that the requirements of these specifications had to be lived up to in every particular, they were forced to improve their methods in each department, and, as a result, there has been a gradual improvement in the quality and finish of structural steel, due to more uniform methods of manufacture, the most important being the control of the finishing temperature, as more steel was formerly spoiled by being finished at too high temperature than in any other way.

The quality of steel depends (1) on its chemical composition; (2) on the treatment it receives in the course of manufacture; and we are learning year by year better to distinguish the results due to each. To-day, at some of the mills, they are getting results that were formerly considered impossible. I refer to rolling the steel into finished product which meets all the requirements of the most rigid specifications, without stopping to make any preliminary tension test whatever. The steel is not allowed to get cold from the time it is cast until it is rolled into the finished product. This, of course, is a great saving of fuel and increases the output. This great advance has been brought about by close observation of the methods of manufacture and the establishment of the relations between the chemical composition and the physical properties. The analysis of each heat is made while the ingots are still in the soaking-pit. The ultimate strength is estimated from its chemical composition, then the heat of steel is rolled on orders where it will apply, due allowance, of course, being made for the thickness of the finished product.

I have made a special point of the heat treatment of steel in connection with work, as the quality of the finished product depends more on it than is generally admitted or understood, and I consider that it is now the most promising field of experiment and research. To-day we hear less of the mysterious failures of steel than ever before, as when a faiulre occurs in the shop or elsewhere, examination shows that in nearly all cases the trouble has been caused by improper treatment, and indicates the necessary improvements required in shop methods to avoid a recurrence of the trouble. In order to prove this, good material has been taken and similar failures have been produced at will by the same treatment. This has brought about in many shops as great an improvement in their methods of working the steel as in its manufacture. The net result of all this is that the consumer is to-day getting a better structure than ever before.

Recent careful scientific investigations have given us valuable information of the character and properties of steel, but there yet remains the important work of showing the direct relation between the results of these investigations and the every-day processes and results obtained in our mills and shops.

There is considerable room for improvement in our ordinary methods of testing structural steel. The conditions under which tests are made should be reduced to a standard as regards the pulling speed and the relation of the width of test piece to thickness of the material. About three widths would be sufficient to cover all ordinary thicknesses and they could be used without materially increasing the cost of the present methods of preparing test pieces. We also need some simple machine for making impact tests, as our ordinary tension tests do not give us all the information required as to the quality of the material to resist shock.

Too much importance is paid to the quench bends. In some cases the cold bends have been entirely omitted and the quench bends considered a reliable test as showing the quality of the material. Now this is all wrong; as soft steel which has been finished at too high temperature, and thus rendered brittle so that it will not stand the ordinary cold bends, may be restored by the heating, and the carbon being so low that the subsequent quenching does not harden this class of material, it then bends 180° flat on itself. Material accepted under these conditions has failed under subsequent shop work. Such material would have been rejected at the mills had the ordinary cold bends been made.

THE POSITION OF PITTSBURG IN THE STEEL trade is thus stated by Mr. Andrew Carnegie, at a recent banquet tendered to him by the Pittsburg Chamber of Commerce:

> There is not a district in this world to which the Pittsburg District cannot to-day send steel and pay the freight and deliver that steel as cheap or cheaper than it can be made at the point of delivery, if we except Colorado, to which the freight is greater than the difference in cost of manufacture at the two points. Should the South be successful in its present attempt to manufacture steel, we may have to except another point. Colorado excepted, the Pittsburg District has the whole world to-day at its feet. Pittsburg is indeed the steel city. I believe Pittsburg to be the best distributing point in the United States. She sits here, with one wing covering the East, the other the West, her beak dipping into the lakes upon the North, and her tail flapping in the Gulf of Mexico in the South. All points of the compass are within her easy reach and all tributary to her. She has that surest element of all for success, an enormous home market for her raw products and the largest army of the most efficient skilled labor in the world.

SPECIAL FEATURES OF THE RESERVOIRS AT THE CAMBRIDGE, MASS., WATER-WORKS.

Within the past few years the city of Cambridge, Mass., has made some extensive improvements to its water-works. Among these are two new reservoirs, storage and distributing, respectively. The Hobbs Brook storage reservoir has a capacity of about 2,500,000,000 gallons, a water surface of 558 acres, and a drainage area of 6.6 sq. miles. The reservoir filled for the first time in a remarkably short period, or between Dec. 16, 1897, and Aug. 20, 1898. The rainfall meanwhile was 33 ins., 71½% of which was, therefore, impounded.

FIG. 1.—DETAILS OF AERATING AND OVERFLOW CHAMBER AND OVERFLOW CONDUIT, HOBBS BROOK RESERVOIR, CAMBRIDGE WATER-WORKS.

Mr. L. M. Hastings, City Engineer.

Overflow and Aerating Chamber, Hobbs Brook Reservoir.

The water from this reservoir flows down the natural bed of the stream, reaching it through the overflow and aerating chamber and the conduit extending through the dam, shown in detail by Fig. 1. Views of the chamber are also shown by Figs. 2 and 3. When the water level rises to a point 3 ins. above the stop planks on the aerating weir it flows through the arched openings at the side of the chamber. When it reaches an elevation 3 ins. higher still the storm relief overflow, or waste weir, 25 ft. in length, comes into service. This waste weir is shown at the left, in Fig. 3.

It may be added that the entire bed of this reservoir was stripped of soil and muck, necessitating the removal of some 1,900,000 cu. yds. of material, nearly all of which was handled by carts at from 16 to 22 cts. per yd., the latter price being paid for most of the work. This, we presume, explains the presence of the boulders in Fig. 3, although some of them may have been hauled in for the slope paving.

The Payson Park Reservoir, Gate House and Asphalt Lining.

There is a fine gate house at the Payson Park reservoir, as shown by the view, Fig. 4. The most interesting feature of this reservoir, however, is the asphalt lining, which was recently exposed for the first time after having been covered with water for about two years. The bottom of the reservoir was originally composed of 6 to 9 ins. of concrete. This proved to be of inferior quality, but as it seemed too good to tear out it was covered with asphalt. The concrete was first thoroughly swept. Then a thin coat of refined Bermudez asphalt, 95% pure, was applied with mops and brushes, as a binder. After this a lining of ½-in. of hot Bermudez asphalt concrete was applied. The concrete was composed of 50% of refined asphalt, 90% pure; 46% of limestone dust, and 4% of flux. This was slung on from dippers, as shown by Fig. 5, the motion being something like that of a man swinging a scythe. Usually the mixture was applied in two or three layers before it was thick enough. The material was bought from Richard Upham, of New York, and applied by Simpson Bros., of Boston. The contract prices were as follows: Refined asphalt for priming coat, $40 per ton; balance, $27.75 per ton; both f. o. b. at Cambridge. Labor, priming coat, ¾ cts., and ½-in. coat, 3½ cts. per sq. ft.

The above information was obtained from Mr. L. M. Hastings, City Engineer of Cambridge, and engineer for this work, by a member of the editorial staff of this journal, who visited the Hobbs Brook reservoir last September. Mr. Hastings kindly offered, at that time, to send us some notes on the appearance of the asphalt lining upon exposure, which he did under date of Oct. 1, as follows:

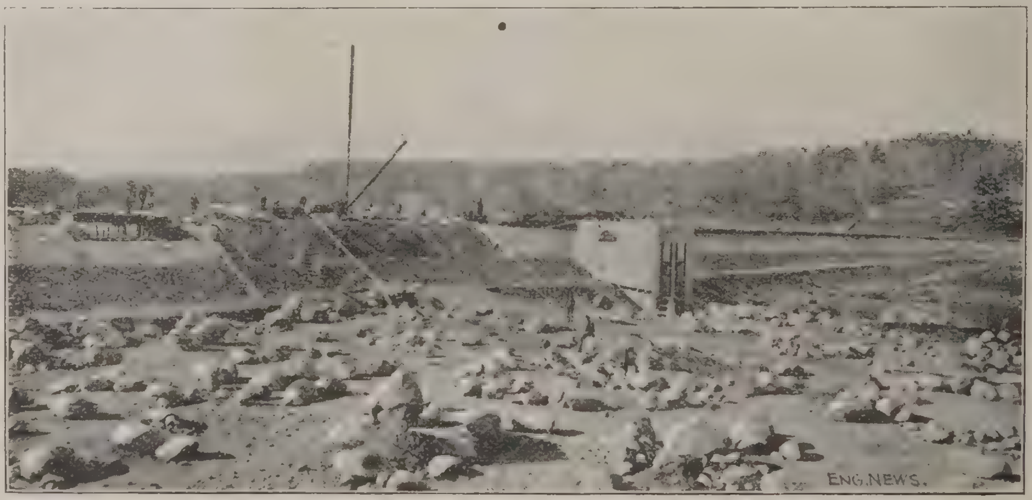

FIG. 2.—VIEW OF DAM, UNDER CONSTRUCTION, INCLUDING OVERFLOW AND AERATING CHAMBER AND WASTE WEIR.

> The asphalt lining of the bottom for the most of the area looks finely, just as well as the day it was laid—bright, sound and hard. Across one end and near the partition wall, however, a very curious thing happened. Numerous blisters appeared in the black lining, which appeared lifted or blown up away from the concrete floor in sizes from 4 or 5 ft. in diameter to 2 or 3 ins. These lifted up to a surprising height, 2 or 3 ft., I should think in some cases, until the sheet of asphalt, originally ½-in. thick, was drawn out very thin. These burst or were punctured and then subsided with a wrinkled appearance. They were all filled with water. From 11 to 13 ft. of water was kept in the other part of the reservoir. The cause of this action is undoubtedly one of two things, or perhaps a combination of each: The inward pressure of ground or spring water, or the pressure of the water from the other compartment of the reservoir, which may not be pefectly tight. When the reservoir was built no water was encountered in the bottom. and so no underdrain was laid. Where the lining of asphalt was not subject to this outside influence, it is in a highly satisfactory condition.

METHODS OF SECURING WATERTIGHT WORK IN SHIP CONSTRUCTION.*

By H. G. Smith.†

It is an impossibility to make all compartments of a vessel absolutely watertight; they can only be made practically so, and when a certain degree of perfection is reached it is a waste of time and labor to proceed further. However, in order to secure practical watertightness, it is necessary to demand absolute watertightness, discretion being left to the Inspection Officer to say when a test is satisfactory. A slight weeping of rivets or joints is immaterial, and more damage is often done in trying to repair them than by leaving them as they are. All compartments that are unsatisfactory at the first test should be refilled after having been stiffened if necessary, and thoroughly recalked throughout.

---

*Abstract of paper read at the sixth general meeting of the Society of Naval Architects and Marine Engineers, held in New York, Nov. 10 and 11, 1898.

†Assistant Naval Constructor, U. S. N., Philadelphia, Pa.

Specifications require that all material shall be calked metal to metal where possible. This is done either by hand or by pneumatic tools, and, when carefully done, I have been unable to detect any difference in the character of the work in the two cases as far as watertightness is concerned. The custom of chipping the edge of an angle bar before calking appears to be unnecessary. Equally good results were obtained on the U. S. S. "Alabama," where the bars were chipped and calked and where simply split and calked. There are many cases where it is necessary to adopt other means than calking for securing watertight work. Some joints are never accessible for calking after the material is fitted and riveted; while others do not prove satisfactory if calking alone is depended upon. Watertight floors in wake of liners on outside plating and inner bottom; bulkheads or decks, in wake of plating of two or more thicknesses; the connections of framing behind armor to the armor shelf, are examples of the second case, and require the use of stopwaters. Various substances are used for this purpose, amongst which may be mentioned the following, viz:—Tarred hemp felt, plain or soaked in red or white lead; canvas soaked in red or white lead; sheet rubber; sheet lead; red lead putty; hempen or lamp-wick gaskets, soaked in white lead; asbestos; lead wire, and in some cases copper wire. Any one of these is satisfactory in a particular case, but different classes of work require different stopwaters. Where the joints of material are close fitting, or can be well drawn together in riveting, a strip of tarred hemp felt is generally used. This is the case with most of the lighter material, one-half inch thick or under, in hull work. Where the parts connected are very rigid, and are apt to stand some distance apart when riveted, a layer of felt is next to useless, as, being thin, it is not compressed between the plates. In these cases a thick layer of some plastic substance, such as red-lead putty, should be used. This will fill all the spaces between the parts as they are drawn together, and on hardening will form a solid joint. Rubber, lead, canvas, asbestos, etc., are principally used in connection with pipe work. In order more thoroughly to test the efficiency of the various materials used as stopwaters, the following experiments were made:

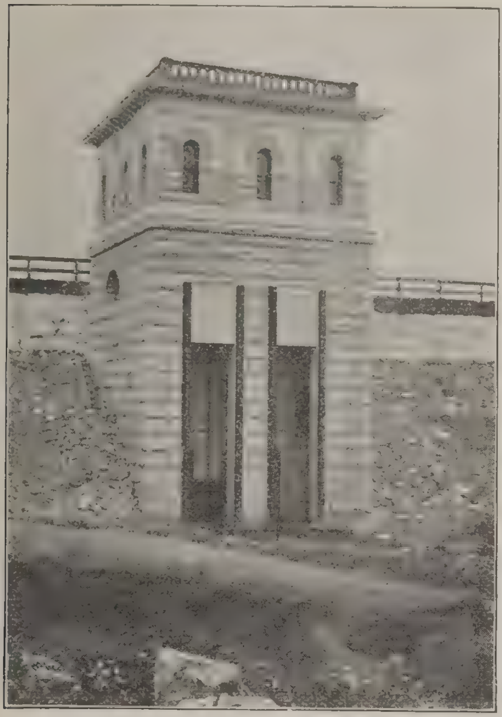

Fig. 3.—View of Overflow and Aerating Chamber.

A cast-iron bend was fitted with blank flanges, in each of which holes were cut, over which smaller flanges could be fitted, using different materials as gaskets. This improvised water tank with its flanges was placed in the open air, where it would be exposed to all kinds of weather. A stand-pipe, fitted with a funnel at its upper end, and about 35 ft. high, was connected to the tank. Water was poured in and the flanges set up until they were quite watertight under a pressure head of 35 ft. The tank was allowed to stand about 3½ months, water being added at intervals to maintain the pressure. At the end of this time all joints were broken, an examination made of the stopwaters, and their condition found to be as follows:

(1) Tarred hemp felt, plain; in thoroughly good condition, no leakage having taken place. (2) Canvas soaked in red lead; quite dry and in thoroughly good condition. (3) Asbestos; some leakage, and where this occurred the material was moldy and partially decayed. (4) Red-lead putty; thoroughly dry, being frozen to the metal, making practically a solid joint. No leakage had occurred. (5) Tarred hemp felt soaked in red lead. The joint was in good condition, except in one place, where a slight leak had occurred. At this point the felt was slowly working out of the joint. (6) Rubber; this gasket had squeezed out somewhat at the edges, and had lost its elastic qualities, but was still effective.

All the joints were now made up anew, light plates that would admit of deflection being used instead of the heavy flanges, and each joint made with new material of the same class as before. After watertightness had been secured with 35 ft. pressure head, the bolts in each flange were eased off until a slight leakage took place. The apparatus was allowed to stand about two months, water being added frequently to maintain the pressure. It was then disconnected and the joints re-examined. The results were as follows:

(1) Tarred hemp felt, plain; slightly rotted. (2) Canvas soaked in red lead; in very good condition, no decay. (3) Asbestos; moldy and somewhat decayed. (4) Red-lead putty; in excellent condition. (5) Tarred hemp felt soaked in white lead; considerably decayed, but not in bad shape. (6) Rubber; somewhat decayed.

Although not extensive nor of sufficient duration to be entirely satisfactory, these tests show in a general way what may be expected of the above materials; that all of them may be used in particular cases and some of them in any case liable to be encountered in ship construction. Red-lead putty is an excellent stopwater, and can always be relied upon. It should be used where there is any doubt as to the proper one needed. It can be made by mixing dry red lead with white-lead paint.

Tarred hemp felt generally makes a very good stopwater if used with discretion. Where constantly subjected to the action of water, however, it is liable to be squeezed out of the joint. Canvas soaked in red lead makes an excellent gasket for sea-valve connections to outside plating or in the joints of piping. Asbestos is used where joints are subject to heat and some substance not easily burnt out is required.

Natural Rust Joints.—Where the parts have not been painted, as between a rivet and the edge of the hole, rust joints will form in a very short time after the application of water pressure, which, if the leaks be but slight at first, will soon become quite tight. If left to themselves, many of the trifling leaks will thus soon disappear. Although not a desirable way of producing watertightness, rust joints cannot be prevented from forming, and the results are satisfactory. I have not ascertained that any material damage has been produced from this cause, but it shows the importance of painting as far as possible all faying surfaces of material, as it is fitted, to prevent corrosion, which will otherwise occur and which might prove serious. It is preferable to test all compartments before they are painted, as the leaks are more easily located.

A coat of paint, or a layer of cement, however, has very little effect in stopping a leak. In two or three cases where compartments were tested in very cold weather, even a heavy coating of ice was insufficient to keep the water from oozing through under pressure, where leaks occurred.

Fig. 5.—Placing Asphalt Lining on the Payson Park Reservoir, Cambridge, Mass.

All countersunk-head rivets should be calked at the head. My experience has been that the head of a countersunk rivet is very rarely tight unless calked. This is due to the fact that the angles of countersink on the rivet and in the plate are somewhat different, the head of the rivet not entirely filling the hole unless very carefully driven. The difference between the case of the countersunk head and the pan head rivet, then, is, that the former is apt to bear against the plate along a line only, and not over a surface, as in the case of the pan head rivet, with consequent greater danger of leakage. Again, the head of a countersunk rivet usually projects beyond the hole, and if leakage occurs, it is generally necessary to chip off the head before the same is accessible for thorough calking. I consider it desirable to avoid the use of these rivets as much as possible.

In bulkhead work much better results are obtained by lapping the butts and seams than by strapping them. Bounding angles and all staple angles and collars should be fitted double, i. e., on each side of the bulkhead. For good results this is imperative. When fitted on one side only the calking is invariably broken when the pressure is applied on the calking side, and it is necessary to fit additional staples or plate collars to remedy this after the bulkhead is completed and tested. The plates, as far as possible, should have their seams parallel throughout. The stiffeners or girders should be fitted in the direction of the shorter length. It is not advisable to fit a horizontal girder or stiffener on a very long bulkhead, unless the same can have cross ties to other bulkheads. Greater stiffness can be attained by putting the same weight of material into a number of shorter vertical stiffeners. If single bounding bars be used, the butt straps to same should be on the opposite side of the bulkhead from the bars themselves, with a liner fitted at the back of the bar at the bottom of the plate, and the ends of the bar calked. Flanged brackets at the bottom of stiffeners give less satisfaction than brackets and angle clips, as the flanged plate has a tendency to straighten when the stiffener is in tension. At the top of a stiffener, where there is less pressure, a flanged plate is generally satisfactory. When stiffened principally on one side, the bulkhead apparently stands better when deflected away from the stiffeners than when toward them.

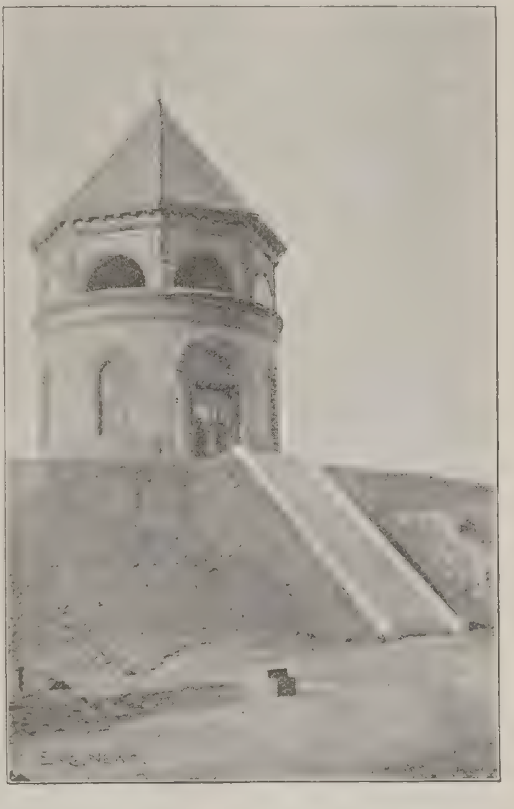

Fig. 4.—View of Gate House, Payson Park Reservoir, Cambridge, Mass.

Summarzing the conclusions already reached, there are certain very important features which, if more generally adopted, will undoubtedly give a much more efficient watertight subdivision of vessels. These are:

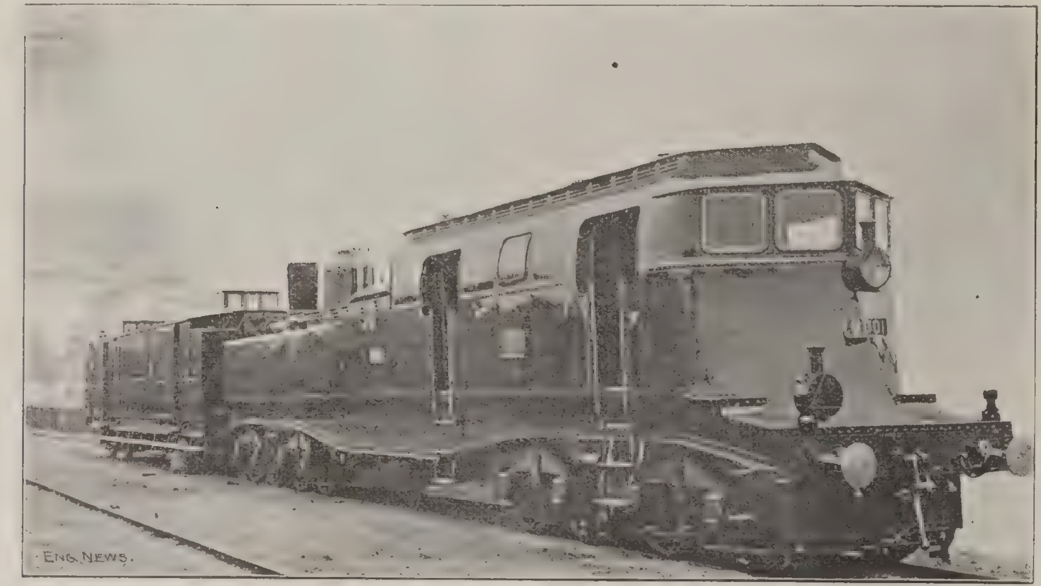
(1) Fitting of efficient rigid bracketing to all stiffeners on bulkheads below the water-line. (2) Fitting of double bounding and staple angles to such parts of all bulkheads as may be below the water-line. (3) Fitting of a vertical stiffening bar or double staples on all water-tight floor plates of a certain size (depending upon the class of vessel), except where the plate is in direct line and adjacent to a bulkhead above. (4) Fitting of the protective deck in two thicknesses instead of three. (5) Fitting of all plating behind armor in one thickness instead of two. (6) The use of double riveted lapped butts and seams instead of strapped butts and seams in the case of the inner bottom, platform and splinter decks and all bulkheads. (7) As an alternative to No. 6, the fitting of a stuffening bar along the seams in the case of all light flush plating fitted with straps.

The first three of these items are imperative, Nos. 4 and 5 very important, and the others desirable. In connection with these must be mentioned a general increase in the stiffness of certain important bulkheads, as already discussed. This I consider the most important feature of all.

THE HEILMANN ELECTRIC LOCOMOTIVE.

About five years ago there was heralded to the world the introduction of a self-contained electric locomotive on a French railway, which was in effect a combination of power station and motor car, and was claimed to combine exceptional properties of speed, power and economy. This machine was invented by Mr. J. J. Heilmann, of the Heilmann Works, manufacturers of steam and electric plant, of Paris, France. The technical papers were not enthusiastic over the design, an analysis of which failed to show advantages commensurate with the disadvantages. The machine was tested in experimental and regular train service on the Western Railway, under the supervision of Mr. Clerault, Superintendent of Motive Power, and "satisfactory" results were reported. In 1896, two more machines, of improved design, were built, and have been tried on the same railway, but the results of these trials have not been made public.

We have recently received from Mr. Drouin, Engineer of the Heilmann Works, particulars of these engines, and the following description of the old and new locomotives will interest many of our readers. We also reproduce herewith a photograph of one of the new locomotives, which shows also a special water-tank car which is attached for long runs. It will be seen that in its external appearance the machine would impress the average observer as a cross between a snow-plough and a military car for a Cuban railway.



VIEW OF THE HEILMANN ELECTRIC LOCOMOTIVE AND ITS WATER CAR ON THE WESTERN RAILWAY OF FRANCE.

The first locomotive on this system, named the "Fusee Electrique" (or "Electric Rocket") was tested in 1893-94 (Eng. News, March 15, 1894). It had a heavy girder framing, and was mounted on two eight-wheel driving trucks. At the rear end was a Lentz boiler, with water tanks on each side, while at the forward end was a 600-HP. horizontal compound steam engine (placed transversely to the longitudinal axis of the machine) running at a speed of 360 revolutons per minute. The engine drove a six-pole dynamo furnishing current to eight motors (one at each axle), while another engine drove a small exciter of constant potential. The engine was controlled by varying the exciter current by means of a rheostat, and was reversed by means of a commutator which reversed the current. The forward part of the engine was enclosed by a large cab. The weight of this engine was about 114 tons, or an average of about 7 tons per wheel.

According to the report made by Mr. Clerault to the International Railway Congress of 1895, the engine has hauled a load of 420 tons for test, and has also hauled trains of 206 tons and 80 tons (exclusive of the engine) at 21½ miles and 29½ miles per hour, respectively, on a grade of 0.8%, 7½ miles long. This was in experimental service on the line between Havre and Beuzeville. On the line between Paris and Mantes, 34.7 miles, the engine hauled regular and experimental trains of 60 to 80 tons at regular express speeds, the maximum speed recorded being 67 miles per hour. The engine was said to be very steady on the track. The coal consumption was gradually reduced from 24.5 to 13.2 pounds per mile. For five trips with trains of 61 and 69 tons (behind the engine), the average consumption was 20 lbs. per mile; 0.114 lbs. per mile per ton of total load (173 to 183 tons), or 0.323 lbs. per mile per ton of net train load (61 to 69 tons).

In 1896, two more of these engines, but of greater power, were built by the Call Company to the design of the Societe de Traction Electrique. These locomotives, as shown by the accompanying cut, are in general similar to the first, having an iron underframe mounted on two eight-wheel driving trucks, with the engine and dynamo at the forward end and the boiler at the rear end of the frame. The wheels are 3.8 ft. in diameter. A metal cab is built over the machinery, and is brought to a point at the front to lessen the air resistance. The total weight is 120 tons, or 7½ tons per wheel, but the machinery has a much greater capacity than that of the former locomotive, having a steam engine of 1,350 I. HP. as compared with 769 I. HP. It is to be noted, however, that for long runs the new engines have to haul specal cars, mounted on two four-wheel trucks and carrying 24 tons of water. One of these cars is equipped with four electric motors, and may be used as an extra engine in hauling very heavy trains.

The new 120-ton locomotives are 61 ft. long over the frames, 8 ft. 10 ins. wide over all, and 13 ft. 9 ins. high from the rail to the top of the smokestack. They have a total wheelbase of 50 ft. 6 ins., the truck wheelbase being 13 ft. 6 ins. The boiler is of the locomotive type, with Belpaire firebox, and is fixed at the middle, the ends being supported on expansion bearings. It has 351 tubes, 1¾ ins. diameter and 12 ft. 6 ins. long. The grate area is 36 sq. ft., and the total heating surface, 1,995.6 sq. ft., of which latter the interior surface of the tubes represents 1,818.4 sq. ft. The coal bunkers are on either side of the boiler, and the water is carried in a tender, as already noted. The engine is of the Willans vertical compound type, having six sets of tandem cylinders (or twelve cylinders in all), the high pressure cylinders being 12 × 16 ins. and the low pressure cylinders 19.2 × 16 ins. This engine runs normally at 400 revolutions per minute, the cranks running in a closed chamber containing oil and water. A separator on the steam pipe prevents water from getting into the cylinders.

At each end of the engine shaft is a six-pole dynamo, furnishing a current of about 1,000 amperes at 450 volts, or of double that intensity for a brief time. These dynamos are coupled in parallel. They are inclosed in steel casings, having suitable manholes and openings for ventilation. They were built by Brown, Boveri & Co. The exciting dynamo is a four-pole machine, which also serves to light the train, furnishing a current of 140 amperes at 115 volts. It is driven by a two-cylinder simple Willans engine of 28 I. HP., having cylinders 8.64 × 5.08 ins., and running at 550 revolutions per minute. On each driving axle is mounted a four-pole motor, rated for 125 HP. (or 1,000 HP. in all), at a speed of 62 miles per hour.

The machine is said to ride very steadily, owing to the absence of the ordinary reciprocating parts and to the balancing of its multi-cylinder vertical engine. Although it can develop considerable power, it does not seem capable of hauling very heavy trains, or of attaining any exceptional speed. One advantage claimed is an economy in coal consumption, but the information furnished us gives no particulars of any work in hauling heavy trains. An engine of 120 tons, with a huge tender in addition, ought to be able to do some real work, but we have no information as to the character of the tests or results obtained.

For general purposes, however, we may compare the figures already given for the first Heilmann electric locomotive with those of some new steam locomotives for fast passenger and freight service on the Great Northern Ry. These engines are of the ten-wheel type, having three driving axles. As shown by recent tests, they can haul passenger trains of 157 tons and freight trains of 417 tons at speeds of 49½ and 34 miles per hour on a division where the maximum grades are 2.2% and the average grade is 1.23% for 48 miles. The weight of engine and tender is 132 tons, and during the test the coal consumption was 152 and 241 lbs. per mile for passenger and freight trains, respectively, making 13.2 and 8.3 miles per ton of coal. From these figures we obtain for the passenger service 0.53 lbs. per mile per ton of total train, or 0.96 lbs. per mile per ton of the net train load. For the freight service the figures per ton per mile are 0.44 lbs. for the total train, or 0.58 lbs. for the net train. In comparing these figures with those of the "Electric Rocket" it must be remembered that the latter represented 62 to 65% of the total train load, while the steam locomotive (and tender) represented only 45.7% of its total passenger train, and 24% of its total freight train.

◆

THE LOWELL TEXTILE SCHOOL.

The annual catalogue of the Lowell, Mass., Textile School for 1898-99, contains information which should be of interest not only to those connected with the textile industries, but to others who are students of educational and social science. In the recent address by Prof. J. B. Johnson, on "A Higher Industrial and Commercial Education" (Eng. News, Aug. 18, 1898), he criticised our existing educational systems as lacking in the very element which it is the object of such schools as the one at Lowell to furnish, viz.: a scientific training especially suitable for the manufacturing industries. In that address he said:

> The most essential conditions of our future material prosperity are, as I conceive them, a specific scientific training for the directors of each and every kind of manufacturing and commercial activity. The imperial and paternal government of Germany has worked out this problem to a most fruitful issue, but probably no other country could duplicate it. England has been trying for ten years to do so, but with poor success; instead of highly educating a few leaders and directors of industry and commerce, they are vainly trying to raise the whole class of apprentices and clerks by a wholesale system of shallow night-school instruction. The great question for us to solve is how to obtain a corresponding scientific training for our industrial officials.

This great question is the one which, as far as the textile industry is concerned, the Lowell school is attempting to solve. As far as we can judge from the catalogue, its plans have been laid broad and deep, with a full knowledge of the scope of the problem, and after a thorough study of the European textile schools, and of the textile school which is developing successfully in Philadelphia. The trustees of the school are incorporated by act of the Massachusetts legislature, and the incorporators are directors or officers of great textile corporations in the state, with an aggregate capital of over $25,000,000. The school was opened Jan. 30, 1897.

The object of the school is to give instruction in the practical knowledge necessary in the cotton, woolen, worsted and other textile industries, in sciences and art as applied to these industries. The equipment consists of high grade machinery specially built to afford facilities for experimental work, and of such variety as is never found in any one textile mill. When all the machinery already arranged for is installed the equipment will be more extensive than that of any other textile school either in America or Europe. The work of the school is carried on in four directions: Day classes, evening classes, popular lectures, and women's department, each adapted for different sets of students. In the day classes there are four separate courses, each of which requires three years for its completion. They are: The cotton manufacturing course; the woolen manufacturing course; the designing course; and chemistry and dyeing. One term of preliminary instruction is given in the first year, consisting of principles of mechanism, machine drawing, textile calculations, elementary designing and elementary chemistry. Towards the end of this term each student elects which of the four regular courses he will follow in his subsequent studies. The evening classes are intended to give instruction to those who are engaged in the mills during the day, to enable them to perfect their knowledge of the branches in which they work, or to acquire knowledge of other processes. Five separate courses are given in evening classes covering the manufacture of cotton and woolen yarns, weaving on all varieties of looms; designing, cloth construction, analysis, and reproduction, color, and textile calculations; and chemistry and dyeing. Popular illustrated lectures on subjects connected with the textile industries are also given, and there are day classes for women in art subjects, especially in textile designing. The tuition fee charged for the day classes is $100 per school year, or $50 per half-year term. The fees for the evening classes vary according to the course. Tools, instruments, textbooks, etc., for students in the day classes cost from $10 to $15. The plant of the school now arranged for will cost $75,000. That the school is already a success so far as number of students is concerned appears from the list of students, numbering 257 in all, of whom 72 are day students. Of the latter 3 are graduates of universities, 6 of schools of technology, 32 of high schools, 13 of grammar schools, and 18 passed entrance examinations, or gave evidence of proficiency.

The school staff is as follows: Wm. W. Crosby, S. B., Principal, and Professor of Mechanics; Fenwick Umpleby, Professor of Textile Design and Fabric Structure; Louis A. Olney, Professor of Chemistry and Dyeing; Edgar H. Barker, Professor of Woolen and Worsted Spinning; Charles C. Hedrick, Professor of Cotton Spinning; Vesper L. George, Professor of Decorative Art; William Nelson, Professor of Weaving. We are indebted to Prof. Barker for a copy of the catalogue.

We shall watch the future progress of this school with great interest.

TESTS OF A NEW IMPULSE WATER-WHEEL.

We illustrate herewith a new form of impulse water wheel, recently invented by Mr. Daniel Hug, of Denver, Colo., and covered by U. S. Patents Nos. 576,828 and 576,849, Feb. 9, 1897. The principal feature of this wheel, which distinguishes it from the Pelton and other impulse wheels in which the buckets are carried on the circumference of the wheel, is the form of the buckets. The form is clearly shown in the illustration. The nozzle is so placed as to throw the jet horizontally into a bucket which is at the lowest point of its travel, and the jet on striking the V-shaped partition in the bucket is split into two halves, which are diverted upward and outward by the curved form of the interior of the bucket. The discharging passage gradually contracts toward the outlet, so that it has to a certain extent the function of a nozzle, the flow of the water being thus retarded while its reactionary power is transmitted to the walls of the bucket. Another feature of Mr. Hug's wheel is a "protector," or frame, closely surrounding the bucket, and into which the bucket discharges the water, so that none of the water is thrown upwardly or carried over the top of the wheel.

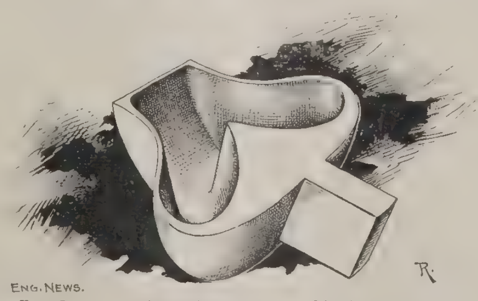

Fig. 5.—Perspective Sketch from Model of Bucket of Hug Water-Wheel.

Several of these wheels have been built by the Denver Engineering Works Co., Denver, Colo., and have given good results in practice. A 12-in. wheel was recently sent to Prof. R. C. Carpenter, of Cornell University, for a complete test with different sizes of nozzle and different heads. We have been favored with a copy of the report, which is one of the most elaborate reports of a water-wheel test that we have ever seen. Tests were made both with and without the frame, showing in some cases a considerable increase of efficiency when the frame was used, but in other cases the increase was unimportant. We give herewith some diagrams in which the results of some of the tests are shown graphically. The efficiencies reached over 85% when the conditions of load, size of nozzle, etc., were favorable, appear to us to be quite remarkable for so small a wheel. The range of power through which the efficiency remains high, as shown by the plotted diagrams, is also, we believe, exceptionally good. It is interesting to note that in all the tests the efficiency was directly proportional to the horsepower developed, as is shown by the inclined straight line plotted on each of the diagrams.

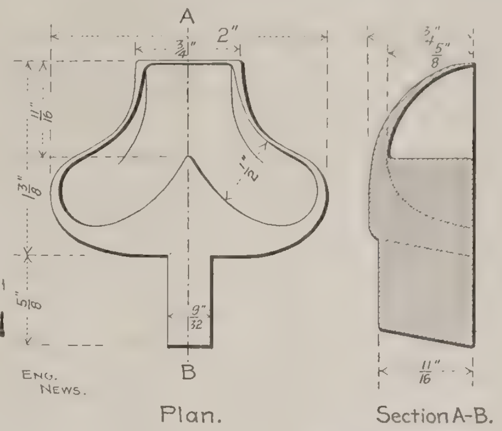

Fig. 2.—Elevation and Plan Drawn from Model of Bucket of Hug Water-Wheel.

Mr. Oscar Knapp, 207 Ross St., Brooklyn, N. Y., is representing Mr. Hug in the East.

THE ATTEMPT TO FORM A POOL, or agreement, by the steel rail manufacturers has failed. Judge E. H. Gary, president of the new Federal Steel Co., said concerning it: "There was no idea of forming a pool. During the week the steel rail manufacturers of this country have been striving to reach a fair and equitable working agreement in regard to division of territory and prices. But at to-day's meeting it was found that it was not possible to reach an agreement, and the plan was abandoned. I think, however, that there is a disposition among steel rail manufacturers to live up to prices, while there is a lack of complete harmony of action just now."

The difficulty seems to have been the refusal of the Carnegie Steel Co. to enter the agreement on the terms proposed.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; 6 *months,* $2.50; 2 *months,* $1.00. *To all other countries in the Postal Union: Regular Edition, One Year,* $7.60 (31 *shillings*); *Thin Paper Edition, One Year,* $6.31 (26 *shillings*). *SINGLE COPIES of any number in current year,* 15 *cents.*

In ordering changes of mailing addresses, state BOTH old and new addresses; notice of change should reach us by Tuesday to be effective for the issue of the current week. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 *means that subscription is paid to the* 32d *week (that is the issue of Aug.* 11) *of the year* 1898; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want noticees, special rates, see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements, by Wednesday noon.*

A notable feature of the new charter of the city of Baltimore is that all contracts are to be awarded by a special board, instead of by the department for which the work is to be done. This board consists of the mayor, comptroller, city register, city solicitor and the president of the second branch of the city council. Proposals must be invited for all work and supplies costing $500 or over, and the contract must be awarded to the "lowest responsible bidder." It seems very doubtful, especially in view of the provision quoted, whether the advantages of this plan will equal its disadvantages. The function of the board is simply to decide who is the lowest responsible bidder. To what contractor the work must go, regardless of whether the lowest bid is too high to give a reasonable profit, only, or too low to secure good work. Perhaps some bidders will be more careful, under this plan, not to bid too low, since the board of award will not be able to show them any favors in the execution of the contract, without collusion between this board and the department having the work in charge. In fact, here seems to lie the principal advantage of the plan, possible increased difficulty in making "deals," because there are two sets of men instead of one to arrange with. But the check does not apply to the frauds which may be practiced in the execution of the work. As to who is the "lowest responsible bidder," the department in charge of the work is better fitted to judge than the board of award. Of course, the advice of this department can, and probably will, be secured. If its advice is followed, the board of award is likely to be a more or less perfunctory body. If its advice is not followed, and the final estimates promise to exceed the original ones, the department involved knows it can, at least, divide the responsibility with the board of award, and thus may be slack in holding the contractor to terms or avoiding extras.

The Heilmann locomotive power-station, or power-station locomotive, which we describe in another column, is one of the most ambitious attempts to apply electricity as a motive power in ordinary railway service which has ever been put into practice. Three engines have been built, two of which have been in use about twelve months, but no information as to their performance is available. Each engine consists essentially of a 1,350-HP. Willans engine, a large boiler, two 600-HP. dynamos, and eight 125-HP. motors, each motor being mounted on one of the driving axles. Great advantages in power, speed and economy are claimed, while the fact that the engine carries its own power plant makes it independent of conductors and central stations. In a brief discussion on the original Heilmann locomotive, in our issue of March 15, 1894, we took occasion to point out a fact that is often overlooked by advocates of electric locomotives. This fact is that the steam locomotive generates power at a much lower cost than any stationary steam plant. Mr. Heilmann uses what is practically a stationary plant, or power-station, which operates under the disadvantage, however, of being carried bodily from place to place. Some of the published accounts, however, state that the new engines were built for use on a certain branch of the Western Ry. If that is the case, it seems most probable that, if electric traction was desired, better economy could have been obtained by the establishment of a stationary central station and an overhead wire, or third-rail conductor, than by the use of the self-contained electric locomotive. It is easy to see, however, why this has not been done. The railway company is not likely to be considering the question of electrical traction except in a very general way, and has no intention of incurring expense for plant for this purpose. It has simply allowed the inventor of this machine to use a certain part of its tracks, and has directed its engineers to make careful tests of the performance.

◆

A favorite argument made in favor of the electric locomotive as a future certainty, is that the extensive introduction of the electric motor car on street railways is but an indication of its future introduction in ordinary railway service. This argument, however, is very easily answered by a comparison of the traffic and requirements of electric railways with those of ordinary steam railways. A little investigation will show that, almost without exception, the electric motor car or locomotive operates under conditions which are entirely different from steam railway service, and which would prevent the economical operation by steam locomotives. The electric railways form in fact a class of themselves, and cannot be considered as ordinary railways which have adopted a new motive power. A frequent service of cars at certain hours on suburban lines or a less frequent service on country lines, cannot well be operated to advantage by ordinary steam locomotives, although the recent introduction of steam cars for light traffic on branch lines has opened a new field for the economical use of steam power. On elevated railways, electric traction can ensure certain economies, but an equally important consideration is the elimination of the noise and dirt from locomotives, which consideration has little or no bearing on ordinary railways. The electric locomotives on the Baltimore & Ohio R. R. are for hauling trains through a long city tunnel, to avoid the inconvenience and discomfort due to smoke from steam engines, but this work is not comparable with ordinary railway work. In fact, all electric railways thus far built have been for purely local traffic. So far as we know, the Heilmann engine is the only attempted application of electricity as a motive power for ordinary railway service, and it must be confessed that the published results give no reason whatever to expect more extended use of the machine. In view of the enormous capacity of modern steam locomotives in point of speed and hauling power, and in view of the close attention that is being given to means of obtaining increased economy in operation, we see no reason to expect the application of the electric locomotive to ordinary railway service.

The progress thus far made toward the creation of a commission to revise the building laws, as provided in the Greater New York Charter, is summarized as follows in a statement recently sent out by the Charity Organization Society:

> A resolution was introduced some months ago, and has passed the Council, providing for a commission of eight members, of whom there shall be one carpenter, one ironworker, one plumber, one mason, one engineer, one architect, one representative of the Board of Fire Underwriters, and one representative of the Corporation Counsel, ex-officio. In the Board of Aldermen this resolution has been referred to a joint committee, consisting of the standing committees on Law, Public Health, and Public Buildings, Lighting and Supplies. To this joint committee has also been referred another resolution on the same subject, introduced by Alderman Folks. This latter resolution provides for a commission of 19 members, which is to include the three Commissioners of Buildings, the Chief of the Fire Department, a representative of the Corporation Counsel, ex-officio; a representative of the Board of Fire Underwriters, two representatives of the Tenement House Committee of 1894, a sanitary engineer, a civil engineer, five architects, two lawyers, and two practical builders. This proposed commission, therefore, consists of five representatives of city departments, seven experts (architects or engineers), two tenement house reformers, two lawyers and two practical builders.

The Society strongly urges that the important work of revising the building code shall not be turned over to a commission constituted almost wholly in the interest of builders and contractors, as would be the case if the first-named resolution were adopted; and approves the commission provided for by the second resolution.

As we pointed out in our issue of Jan. 20, 1898, the excellence or the reverse of the new code will depend very much upon the character and ability of the commission which shall formulate it. Of the two commissions which are proposed, the larger will, we think, appeal to engineers and architects as presenting the greatest number of favorable features. The preponderating position of the building interests in the commission of eight and the manifest unwisdom of asking these interests to form a law for the regulation and restraint of their own business for the sake of the public health and safety, seem to decide its inferiority, as the Charity Organization Society well says. The commission of 19, while somewhat unwieldly in point of numbers, gives, on the contrary, due representation to all interests without giving a preponderating influence to any single one. It also provides the necessary strong element of expert knowledge in the large number of engineer and architect members, which it specifies. Further, the larger commission will permit a proper representation of the needs of the suburban and semi-rural portions of the city as well as those of the residence, tenement house, and office building districts. The value of the new code, after all is said, however, will depend upon the character and ability of the expert members of the commission. Many of the conditions of the present building laws can be remedied successfully by expert engineers only, who are thoroughly familiar with the latest advances made in the knowledge of the strength and endurance of materials, and who will apply this knowledge with an unbiased mind. Engineers can do much toward securing the appointment of such men, and if they choose to neglect the opportunity, they have little cause to blame anyone but themselves should the new code perpetuate the well-known crudities and unwise and oppressive restrictions that occur in the present building laws.

THE PASSING OF THE CANAL.

In our issue of Nov. 10, in commenting on the prospective abandonment of the famous old Delaware & Hudson Canal, we referred to the probability that a few years more will see the entire disappearance of the old-time canal-boat as a vehicle for freight transportation. Men now living can remember when the canals of the Middle States were important avenues for passenger transportation, as well as carriers of all classes of freight. The passenger traffic forsook the canals at an early period in the history of the railway; the general merchandise traffic soon followed; and for many years the only business left to the canals has been the carriage of the cheapest and coarsest class of bulk freights. Even in this field, however, the continual cheapening of rail transportation has gradually drawn business away from the canals. The Erie Canal during the pres-

ent season has carried hardly any wheat, notwithstanding the enormous shipments of this cereal to Atlantic ports; yet wheat was one of its chiefest items of traffic only a few years ago. Over 36 million bushels of wheat were transported on the New York state canals in 1893; but during the present season canal shipments of wheat to New York to Oct. 1 aggregated only 40,000 bushels.

Closely following the announcement of the prospective abandonment of the Delaware & Hudson Canal comes the news that Maryland has decided to dispose of all its interest in the old Chesapeake & Ohio Canal, which has cost the state first and last about $25,000,000. It was offered for sale by the state three years ago; but the only bids received were rejected. The only value of the canal at the present time is as the right of way for a railway line to parallel the Baltimore & Ohio; and it is probable that that company will endeavor to secure it to prevent such an outcome.

The question is often asked why the river and canal transportation routes in this country have been gradually abandoned, while in Europe, notwithstanding the fact that a network of railways covers the country, the traffic on both artificial and natural waterways is steadily maintained. An answer to this question which has been given so often that it has come to be generally believed, is that in the United States the railway companies at an early period secured control of canals for the purpose of wrecking them as transportation routes and getting rid of their competition. There is doubtless a certain amount of truth in this statement, and there was much more truth in it a score of years ago than at the present day. But it is not the real underlying reason for the decadence of water transportation routes in this country. The real reason is that under American commercial conditions freight can be moved at less cost by rail routes than by any system of river or canal transportation. When we say this we speak, of course, in a general way. For such traffic as the transport of coal down the rivers of the Ohio valley, for example, the river transportation, by reason of the peculiar methods by which it is conducted, is cheaper by far than any possible rail transportation. These and similar exceptional instances, however, do not affect the truth of the general statement.

It is of interest to inquire the reasons why rail transportation in this country is so much cheaper and water transportation is so much more expensive than in Europe. First and most important is the larger capacity cars, and more powerful locomotives of American railways, permitting the hauling of heavier train loads. The great volume of traffic and the long hauls make these large cars and long trains possible and economical, as they would not be in a country of smaller area, or one in which the products of different sections are not interchanged on such an enormous scale. Only those intimately familiar with railway matters appreciate the great advancement that has been made in railway practice in the United States during the past two decades. American railway managers have led the world in adapting the railway to the transportation of the cheapest class of bulk freights. Compared with American practice, foreign freight traffic seems like toy railroading.

Another thing which has made possible the cheap movement of freight in this country is the fact that so far as freight traffic is concerned, the railways of the country are operated as a single system. The interchanage of freight cars between different railway companies, enabling a car to travel from one end of the country to the other without transfer of its lading, has saved literally billions of dollars in the cost of handling freight traffic since it was established. Nowhere else in the world is there anything like such a vast system of freight car interchange in operation.

Still another reason why railways have superseded water routes in this country is that all our machinery for the production and distribution of goods is suited to rail rather than to water transport. Most American manufacturing plants of any size have railway sidings and spur tracks running into their yards and often into the buildings themselves, so that raw material is received and finished goods are loaded without any wagon transportation. Comparatively few manufactories except those in seaboard cities or on the Great Lakes are located on a water front.

In the United States the railway has preceded civilization over a large part of its area. The railway and not the river was the original avenue of transportation, and in the building of manufactories, warehouses, etc., everything has been planned with a view to the use of the railway. In Europe things are quite different. European cities with their warehouses were built before the railway era, and convenience to water transportation routes influenced the location of most of them.

The real underlying reason, then, for the abandonment of barge canals in this country is not, as has been so frequently asserted, the political and financial manipulation of the railway companies. The real reason is that bulk freights can under American conditions be carried more cheaply by rail than they can on rivers or canals.

The average railway freight rate per ton-mile for the United States, according to "Poor's Manual," was 1.057 cts. in 1885. In 1897 it had fallen to 0.783 ct. Had the freight shippers of the United States paid the same freight rate per ton in 1897 that they did in 1885, the railways would have increased their profits by more than $268,000,000. This enormous reduction in the charge for carrying freight was made possible by the great increase in the average freight train load. Notwithstanding the fact that the railways received on the average only three-fourths the money for carrying a ton a mile in 1897 that they did in 1885, the average earnings per mile run by freight trains were actually greater in 1897.

We are aware that the past is not a sure guide to future. It is certain that so rapid a reduction in freight rates as has gone on for the past thirty years cannot take place in the future. On the other hand, there is no reason to believe that a final limit has been reached in the cost of transporting bulk freights by rail. Steel cars, and still more powerful locomotives, economies in the methods of loading and unloading cars, and better terminal facilities are some of the means by which further savings will certainly be made.

We do not look for any considerable reduction in the rates on high-class merchandise and "less than carload" shipments. On traffic of this sort the railways are now charging probably less than the total cost of transportation. We do believe, however, that in the handling of bulk freights in great quantities on through shipments, by the use of special rolling stock and, perhaps, of specially-built lines of railway, opportunities exist for the movement of freights by rail at a cost much lower than has yet been deemed possible. Remembering that it is in the coarsest and cheapest class of bulk freights alone that the canal is claimed to be able to compete at all with the railway, it is easy to see that in the near future the old-time barge canal, which is already at the limit of its usefulness, will be left far behind in the competition.

In the light of the plain and well-known facts, which are above enumerated, what would be thought of a company which should propose at the present day to build one of the old-time barge canals as a business venture? Its promoters would be deemed fit candidates for a lunatic asylum. They would be told by financiers that the day of canals is past. That they might as well try to exploit anew the cable system for street railway traction, just when the last of the cable machinery is going to the scrap heap, to be replaced by electric traction, as to propose the building of a new barge canal.

We do not know of any private company which proposes at the present day to build a barge canal; but we do know that the United States government is now actually engaged in constructing such a canal between the Illinois and the Mississippi rivers, in calm disregard of the fact that the day of usefulness for such a waterway has passed. Upon this piece of monumental folly the government has already expended about $2,000,000; and if it carries the work to completion about $8,000,000 to $10,000,000 additional will be thrown away.

It may be of interest to trace the history of this work. During the '70's a large amount of agitation was carried on in the States of Iowa, Illinois, Wisconsin and Minnesota to induce the general government to undertake the building of a canal from the Mississippi River at or near Rock Island, Ill., eastward to the Illinois River, where the existing Illinois & Michigan Canal would continue the waterway to Chicago. Various Boards of Trade and other commercial organizations, both in the West and in the East, adopted resolutions favoring the project; and finally in the early '80's, Congress made a small appropriation for a survey of the route. In the Report of the Chief of Engineers for 1883 we find a record of the survey, together with a statement of the commercial advantages which the new route was to offer. The chief argument for the canal was that it would in effect extend the advantages of the cheap freight rates to and from the East, which Chicago enjoyed to the whole territory covered by the upper Mississippi. A large part of the argument for the canal was based on the idea not that the canal itself would carry the traffic, but that its competition would compel the railways to reduce the rates on the traffic which they carried. As evidence of the need of a reduction in the railway freight rates, a table was given of the average freight rates per ton-mile on several of the leading railways running west from Chicago. We present these figures here, and have added to them the corresponding figures for the same companies for the year 1897, as follows:

Railway.	Average freight rate per ton mile, cts. 1882.	1897.
Ill. Central	1.41	0.67
Chicago & Alton	1.03	0.76
Chicago, Burl. & Quincy	1.19	0.86
Chicago, Rock Island & Pac	1.22	0.97
Chicago & Northwestern	1.46	1.09
Chicago, Milwaukee & St. P	1.77	1.01

It will be seen at once that even if it were worth while to build the canal 15 years ago as a lever for reducing freight rates, it does not at all follow that it would be worth while to-day for the same purpose.

Other changes in commercial conditions have greatly altered the aspect of this canal enterprise since it was first projected. At that time Chicago was the outlet for the whole Northwest. The wheat of Iowa and Minnesota and such part of Dakota as was then under cultivation was gathered at St. Paul and Minneapolis and shipped thence to Chicago. The ports at the head of Lake Superior had hardly begun to cut any figure in the grain movement. In 1880 the total receipts of flour and grain at Chicago aggregated 165,855,000 bushels, while Duluth had only 7,617,000 bushels. In 1896, the ports on Lake Superior sent eastward 90,700,000 bushels of grain and 8,800,000 barrels of flour. Thus the whole Northwest, for the supposed benefit of which the Hennepin Canal was originally planned, has now a far better outlet to the east by way of Lake Superior than it could ever have by way of Chicago.

Again, it was supposed by those who originally promoted the Hennepin Canal enterprise that the railways west of the Mississippi would deliver their products to canal barges at the various river towns. It was not foreseen that the railways which collected this grain would prefer to carry it through to the lake port of its destination, and would arrange their freight rates to accomplish this in any event. Neither was it foreseen, though it ought to have been, that it would cost actually less to haul a loaded car from the Mississippi River to Chicago and discharge its lading there than it would to load a little canal barge, tow it over the long stretch of river and canal navigation, handle it in the long chain of locks of the Hennepin and Illinois River canals, and finally deliver its contents to the Chicago elevator. These locks, we may add, are alone sufficient to make traffic through the Hennepin canal absurd as a business proposition.

We need take no more space, however, to prove that this enterprise has long lost the little reason for existence that it once had. The fact is that the public has for years taken no interest in, and has forgotten all about, the Hennepin Canal. Probably nine-tenths of the members of the Chambers of Commerce and Boards of Trade that once adopted strong resolutions in its favor, would now be puzzled to tell where it is. If Congress, in a spasm of wisdom, should decide to drop the whole enterprise where it stands, and refuse to throw good money after bad any longer, we venture to say that no protest would be heard except from the few who hope to profit by the government's expenditure on the work.

Returning now to our general subject of the transfer of traffic from the canals to the railways, it is of interest to note the experience of Canada. The Dominion has expended about $80,000,000 on its canals, and its total revenues therefrom are about $340,000 per annum. The interest on the original outlay, most of which is still represented by bonds, and the cost of maintenance and operation form one of the heaviest items in the government's expenses, and so far as the canals are beneficial, the benefit must be sought in the indirect returns. Some of the canals along the St. Lawrence and the Welland and Sault canals have traffic enough to justify their existence, but the branch canals, such as the Rideau and the Trent, are admitted to be no longer worth the cost of keeping them in repair and operating them. The Trent Canal is still under construction, but appropriations for it are made year after year merely to give the district in which it lies a share of the "pie," not because anyone believes in its commercial value. The Rideau Canal in 1895 cost for maintenance, operation and interest on its cost about $280,000. The total traffic which it carried was 88,700 tons, most of it cordwood and lumber, and the tolls amounted to about $7,000. As for the St. Lawrence canals, they are being enlarged to admit vessels of 14-ft. draft, to accommodate through traffic from the Lakes to the seaboard, and in the hope of diverting a large volume of the traffic which now goes to United States ports. How far they will be successful remains to be seen; but many believe that they will never carry sufficient traffic to justify the millions that have been expended upon them.

In conclusion, it is of interest to note what one of the ablest of American business men, Mr. Andrew Carnegie, has recently said concerning the relative economy of canal and rail transportation. In his speech before the Pittsburg Chamber of Commerce on Nov. 10, Mr. Carnegie spoke of the projected deep waterway from Lake Erie to the Ohio River, as follows:

> Touching the all-important matter of transportation leads me to refer to my connection with the project for making Pittsburg a lake port by water communication. It has been pointed out that I was the first to suggest in a speech to the legislature that the abandoned canal should be replaced by a deeper one which should lead the waters of Lake Erie into the Ohio. Conditions, however, have changed. Such has been the progress of railway development that, if we had a canal to-day from Lake Erie through the Ohio Valley to Beaver, and it was opened free of toll like the Erie Canal, we could not afford to put boats upon it.
>
> I have never concealed my opinion that even if we had a 15-ft. ship canal, the large lake steamers would not come to Pittsburg. It takes a steamer carrying 7,000 tons of ore to live at present rates—within five years, the lake carriers will be of 10,000 tons, and it will be much cheaper to transfer its cargo at the lakes into smaller boats than to attempt to send the monster through the canal. But more than this, it is cheaper to-day to transfer the ore to 50-ton cars and bring it to our works in Pittsburg over our railway than it would be to bring it by canal.
>
> I do not wish to appear even by silence to be considered a party to any attempt to entice private capital to invest in building a canal between Pittsburg and the lakes, because I am convinced that this capital would be entirely lost; if the canal were completed, the existing railroads could and would perform its service cheaper and more satisfactorily, because they can run all the year round.

It should be especially noticed that the proposed Lake Erie & Ohio River Canal, to which Mr. Carnegie refers, was not to be a small barge canal such as we have discussed above, but a waterway of 15 ft. depth, able to carry good-sized steamers and barges. We have ourselves felt that there was at least a chance that such a waterway from Lake Erie to Pittsburg might prove a financial success, although we have seen small prospect of its actual construction. If Mr. Carnegie is correct, however, and the 50-ton freight car is a cheaper carrier than the boats on such a canal, then is it all the more certain that all the old-time small barge canals are doomed to early abandonment, no matter how much money may be expended on them from state or national treasuries.

◆

LETTERS TO THE EDITOR.

The American Railway Engineering and Maintenance-of-Way Association.

Sir: In your issue of Nov. 3, in commenting on the recent preliminary steps taken to organize an association of Engineering and Maintenance-of-Way officials of American railways, I am sorry to note that your criticism was unfavorable to the formation of such an organization. Your main objection appears to be that there are already sufficient numbers of engineering societies to engross the attention of the professional engineer, and that the new society or association is superfluous.

As Secretary of the newly-formed association I have had rare opportunity to note the widespread interest which the mention of this association has enlisted from the purely engineering and maintenance-of-way officials of the American railways. Out of perhaps 400 communications, only about 3% have expressed any opposition to the formation of a Maintenance-of-Way Association.

To the writer it appears that there is as much need for an association to deal with maintenance-of-way matters as there is of a Master Car Builders' and Master Mechanics' Association, which treats of equipment, or an American Railway Association to discuss questions of transportation.

The railways of the United States are properly divided into three sub-operating departments, which are Maintenance-of-Way, Maintenance of Equipment, and Conducting Transportation. Taking into consideration the general expenses, the proportion of expense in operations of the railways is about as follows:

Maintenance-of-Way	19.5%
Maintenance of Equipment	15.5%
Conducting Transportation	54.0%
General	11.0%
Total	100.0%

The expenditure of the 19.5%, or a sum equal to $150,000,000 to $200,000,000 annually in the Maintenance-of-Way department of railways deserves as much consideration at the hands of the officials in charge of such departments as the $100,000,000 to $125,000,000 expended in the Maintenance of Equipment Department but as a matter of fact, the latter department gives more attention to uniformity of methods and aims more to a united or uniform system for the entire railway mileage of the country than the Maintenance-of-Way department. It is true that this is largely due to the necessity of interchange which prevails in the Rolling Stock department, and which does not apply to the other department; but it cannot be successfully contradicted that a Maintenance-of-Way Association, embodying in its organization the best talent in its particular line, would result in a vast amount of good to American railways. It is this cause that has brought the Maintenance of Equipment department to its present high state of development and efficiency.

The matter of supreme importance is to organize the Maintenance-of-Way Association along proper lines. Many favor the membership to be by railway companies, or an organization similar to the American Railway Association and the Master Car Builders' Association. Others, and by far the larger number, favor an individual membership restricted to railway engineers and maintenance-of-way officials above a prescribed grade, excluding all engineers from eligibility who are not directly connected with railway maintenance-of-way work. For they contend that it is to be a specialty, having for its aim the advancement of the theory and practice of railway engineering and maintenance-of-way work, which is a field broad enough in its extent to merit the sole attention of the association. Those contending for company membership hold that the results of the association would be adopted by the various railways more readily than if such results were the opinions of an association of individuals as members—in short, the benefit to accrue to the railways would be to the maintenance-of-way department what the American Railway Association is to the transportation department.

It is apparent, therefore, that the future of the organization depends upon its being launched on proper lines, and the subject is of such vital importance to the railways that it should receive the serious thought not only of the maintenance-of-way officials, but of all officers having charge of railway operation, and a full attendance at the meeting in Buffalo, in March, 1899, is desirable. Respectfully,

L. C. Fritch,
Secretary American Railway Engineering and Maintenance-of-Way Association.
Washington, Ind., Nov. 15, 1898.

Notes of an Engineer in Colorado.

Sir: The railroads entering Leadville present a fine opportunity for a study of the different types of mountain roads, and for a comparison of the merits of direct alinement and heavy grades vs. longer lines and easy grades. The Denver, Leadville & Gunnison and the Colorado Midland roads are fair samples of the first type, and the Denver & Rio Grande standard gage of the second.

The D., L & G. (narrow gage) has an 11,500 elevation at Boreas and one nearly as high at Fremont Pass, and has much 4% grade and a heavy snow-fall in the winter to battle with. Formerly Leadville was reached by a branch from Buena Vista, 35 miles south of Leadville. Though this line was 28 miles longer (179 miles) than the present one, it had but one 10,000 ft. elevation, no snow to bother and only 2% grades. The road has never paid since the branching off point was changed from Buena Vista to Como. This road continues from Buena Vista on southwest to Gunnison, climbing up to the Alpine tunnel through the Continental Divide at an elevation of 11,623 ft.

The Colorado Midland is the most notable example of broad gage roads belonging to the first type that can be found. The main line from Colorado Springs to New Castle is 234 miles long and cost between $19,000,000 and $20,000,000. The greater part cost about $100,000 per mile, and the line is said to have been the most expensive to construct of any in the world. The country is very difficult. The maximum grade is 4%, reaching from Manitou Iron Springs to Cascade Canyon, and it is equated on curves at the rate of 0.06 ft. per 100 ft. The maximum curvature is 16°. For the remainder of the line the maximum grade is 3%, including that over the Continental Divide. The distance from Colorado Springs to Leadville is 135 miles. (From New Castle to Rifle—13.4 miles—the Colorado Midland uses the track of the Denver & Rio Grande, and from there to Grand Junction—62 miles—they both run over the Rio Grande Junction Ry.). The Midland has a total trackage of its own of 357 miles, including several branches.

About 17 miles west of Leadville the line crosses the Continental Divide. As first built, the road pierced the divide with the Hagerman tunnel, but afterwards the Busk-Ivanhoe tunnel was built. (Eng. News, Jan. 17, 1891, and Aug. 25, 1892.) The Hagerman tunnel is 2,061 ft. long, and is at an elevation of 11,528 ft. The high line running through here was very expensive to operate, so that in July, 1890, work was begun on the Busk tunnel, the first trains running through in December, 1893.

It was estimated that there would be a saving of maintenance charges of $70,000 per year by doing away with the surface line. There were 13 snow-sheds, aggregating a mile in length, and 12 bridges and trestles—one of them 1,200 ft. long and 84 ft. high. Besides the maintenance charges there were the delays by snow and the loss of patronage due to the same; by the new line there was also the saving of 7 miles in distance, 580 ft. in elevation and about 2,000° in curvature to go to lightening the operating expenses. So when it was calculated that the tunnel could be built for $1,000,000, the railway company readily guaranteed the 7% on the cost of construction to the Busk Tunnel Ry. Co. The cost, however, was $1,250,000, and the Colorado Midland Ry. Co. contracted to pay 25 cts. for each passenger and each ton of freight hauled through the tunnel.

The railway company went into the hands of a receiver about 1894. but was reorganized the latter part of last year. The receiver, Mr. Geo. W. Ristine, was elected president and general manager, and at once went to work to try to break the contract in the courts. An offer was made to pay 3%, and then 4%, in place of 7%. The parties seem to now be in a fair way to agree. The Colorado Midland has been running trains over the old route, over the summit, for a year or two past. Most of the track had been torn up, and this had to be replaced and the trestles and snow-sheds put into shape before using.

The west portal of the Busk tunnel has an elevation of 10,945 ft., while the summit overhead the tunnel is about 12,000 ft. The tunnel cross-section is 15 ft. wide by 21 ft. high, while that of the older Hagerman tunnel is 15 × 19 ft. The maximum grade on both sides of the divide is 3%.

Turning now to the Denver & Rio Grande road, we find that it has followed the main drainage channels of the country as far as possible, thus securing water grades for its lines. While this has usually lengthened the general route, the avoidance of sharp curves and heavy grades has more than compensated for it. Thus from Colorado Springs to Leadville by the Colorado Midland is 138 miles, and it is only 157 miles from Pueblo by the Denver & Rio Grande, though Pueblo is 45 miles south of Colorado Springs and the general route is much longer. Again, from Leadville to Glenwood by each line is about 90 miles. The general route by the Denver & Rio Grande is longer. The maximum grade for west-bound trains on the Denver & Rio Grande is 1.42%, and 3% for the Colorado Midland, being 3% on the west slope for both roads. The maximum curvature on both sides of the divide on the Colorado Midland is 16°; on the Denver & Rio Grande it is 10° on the east side and 12° on the west side.

The operating expenses, due to much easier grades, lighter curves and less snow, and also the maintenance charges due to much less trestling to keep up, show very much in favor of the Denver & Rio Grande. This road has 10° maximum curves (except one of 12° in the Royal Gorge) and 1.42% maximum grades (compensated) for its three-rail line from Denver to Pueblo and on to Leadville. Leadville is not on the main line, and only passenger trains run through it. West-bound trains leave the main line at Malta for Leadville, and in the 5 miles there is a rise of 620 ft., with a maximum grade of 3%, requiring a helper engine. Continuing on west, the main line is reached at Leadville Junction.

Leadville.—Leadville has been a noted mining camp since 1876, when the silver and lead carbonates which gave it its present name were discovered. The original camp of California Gulch produced nearly $5,000,000 in gold from the placers between 1859 and 1862, after which it was nearly abandoned. Between 1876 and 1896 the Leadville district is said to have produced precious metals to the value of $206,000,000. Among the mines which have given celebrity to the town are the Little Pittsburg, which went far toward making the fortunes of several of the wealthiest men in Colorado; the Robert

E. Lee, which yielded $118,000 in a single day; the Maid of Erin, Little Johnnie and many others. The carbonate deposits, of which the city is the center, are said to cover an area of 60 miles in length north and south by 10 miles in width. Over 30,000 mining locations have been made near the city, but the production has all come from about 50 mines. Since the slump in silver, Leadville, of course, has suffered severely; and from June, 1896, to March, 1897, a great strike of the miners was on that paralyzed the industrial interests of the town for the time and threatens to have left permanent bad effects.

Many of the largest mines here lie in the "Leadville Basin," being known as "down town mines" in distinction from those on the high mountains east of town. In all these mines, no sooner do the shafts reach the level of the ore bodies than enormous bodies of water are encountered. These have for years been pumped out at a cost of thousands of dollars per month. During the strike the operation of pumping this water out got to be decidedly monotonous, so the owners of some of the larger mines pulled their pumps, when the mines soon filled up. Others followed suit, so that at the present time there is but one small property in the entire area operating, which ships about 25 tons of iron ore per day to Pueblo.

The Leadville Pumping Association has been formed, composed of the owners and lessees of all the ground in this basin, for the purpose of pumping out the water and keeping it drained for a period of eight years, the expense to be divided equitably. Sufficient machinery has been bought, and $90,000 has been subscribed by the members and the merchants of the town for prosecuting work. It is figured that it will take fully three months to drain the workings now, and then then over a month to retimber and clean the shafts and drifts. As the state was put to an expense of about $300,000 in maintaining order during the labor troubles, it has been a very expensive strike all around.

Of late years manganese iron ores have come to be an important part of the product. One mine ships from 100 to 200 tons per day to the Illinois Steel Works, and also ships heavily to the Bessemer Steel Works at Pueblo.

Since 1893 much attention has been paid to prospecting gold properties in this region, with the result that extensive bodies of gold ore have been discovered. The center of the gold bearing territory is Breece Hill, north of California Gulch. The Little Johnnie mine here is said to be the greatest gold mine in the country to-day.

I took a trip into the Yak tunnel, that is being bored into Breece Hill for the purpose of tapping the rich ore bodies and to serve for transportation and drainage for the different mines passed through. The tunnel is now in 7,000 ft., and has only lately pierced the Breece Hill region. It will strike the tunnel company's property, located on the top of Breece Hill, at a depth of 1,275 ft. It is to be extended for 7,000 ft. further, or 14,000 ft. in all. All water encountered is drained or pumped into the tunnel to be drawn out through the mouth in California Gulch. Near the mouth of the tunnel is the air compressor plant, which is operated by water power obtained from a supply main for the city water-works that passes by here. The 335 ft. head produces about 85 HP. when water is plentiful, and the discharge water is returned to the main to pass on down to the city.

The total output of ore of all kinds at Leadville has lately averaged about 1,800 tons per day. The Arkansas Valley Smelting Co.'s smelter is one of the largest in the West, and that of the Union Smelting Co. is also quite large. These work up much of the ore that would not pay to ship.

The Leadville water-works are owned by a private company. Mr. C. N. Priddy is superintendent. Owing to the high altitude there is much difficulty in keeping the system in operation during the winter. Until 1895 the east fork of the Arkansas River (the only considerable stream of this locality) was tapped by an open ditch, called the Oro ditch. Then the water company laid a 36-in. wooden pipe line in this ditch. The pipe draws water from the river and is 33,000 ft. long. It follows the ditch all the way except for one cut through a ridge and one inverted siphon across a gulch, called Evans Gulch. The former shortens the line from 6,130 ft. to 1,570 ft. The latter is 900 ft. long and sustains a static head of 100 ft. at the bottom and a hydraulic head of 46 ft. The hydraulic grade line falls 11 ft. to the mile. The banding varies from 75 ft. per 100 ft. at the head to 225 at the end (where the static head is 66 ft.), and 375 at the bottom of the siphon. The pipe line discharges into a reservoir near Stray Horse Gulch, that runs through the north part of town. The pipe was built of Louisiana pine staves. Mr. Thos. W. Jaycox. M. Am. Soc. C. E., of Leadville, was the engineer.

There is a 50 million gallon reservoir on Big Evans Gulch and a 25 million one on Empire Gulch. These and the Iowa Gulch—all from the range east of town—are the additional sources of supply.

In the operation of the distribution system much ingenuity is displayed in the keeping of the pipes clear of ice. All service pipes are enclosed in a double wood box, with air space between. Steam hose is let down the stop box and the pipe thawed out when frozen. The service pipes are lead or galvanized iron, extra thick. A steam engine for thawing out mains and hydrants is in constant use during the winter. The hydrants are tested every day. They are double-case, and when frozen the barrel or inside part is pulled out and steam is forced onto the ice at the bottom. When the mains freeze, a hole is bored down into the pipe where needed and the steam hose inserted. The nozzle of this has one jet in front and four behind, the reaction of the ones behind forcing the hose along through the ice as fast as melted large enough, and the rear jets also melt the surrounding ice left behind as it travels. The hose is extra thick, to avoid cooling too fast. All pipe is buried 6 to 7 ft. deep, but this does not prevent freezing.

The headwaters of the Arkansas (near Tennessee Pass) often freeze up, thus cutting off the supply from that source for months at a time. During the last winter, from the beginning of November to the end of February, only once or twice did the temperature at the headwaters reach as high as the freezing point. January, February and March are usually the low water months.

The distribution system has 156 Holly single and double nozzle 6-in. hydrants, with 4-in. connections to street mains. Nearly all mains are not less than 6-in.

Glenwood Springs and Aspen.—Resuming the journey west from Leadville over the Denver & Rio Grande, the Tennessee Pass tunnel is reached at 6 miles. The old narrow gage grade that passed over the summit is plainly visible for a long ways each side of the tunnel. This is the summit of the Continental Divide, the drainage running on the east to the Atlantic and on the west to the Pacific. The tunnel is about a half mile long, and is timbered. On leaving the west or north end a descending grade is begun that reaches to Minturn, 25 miles. The average fall is over 100 ft. per mile, with a maximum of 3%. The road does not rejoin the old narrow-gage route until several miles from the tunnel, the latter having much more development and lighter grades. It then enters the valley of the Eagle River. At 10 miles, Pando tunnel—cut through solid granite—is reached. Below this is an interesting piece of railway construction, where the Eagle River is diverted through a cut across a ridge that separates it from another valley. This leaves room for the railway to occupy the entire bottom of the river valley until the side valley joins it about a half mile down. The diversion is quite inexpensive. It was made for the purpose of retaining the ruling gradient of the road, which made it necessary to cut below the natural channel of the river in the valley.

There is much attractive scenery all the way, and passing Red Cliff—a noted mining town—the Eagle River Canyon is entered. This extends to Minturn—8 miles—and is grandly picturesque. Miners' cabins can be seen at the mouths of tunnels and drifts hundreds of feet above the track. The town of Gilman, which is simply a collection of cabins, reminding one of the cliff-dwellers, is said to be 1,000 ft. above the bed of the canyon.

About 20 miles above Glenwood the canyon of the Grand River is entered. This is a peculiar and picturesque canyon, the rocks being of volcanic origin. Just below the mouth of this, Glenwood Springs is reached. I stopped over here for two nights, taking a run up to Aspen and return in the day time. Glenwood is justly noted for her splendid health-restoring springs and balmy climate. On account of its being in a park protected by mountains on all sides, the winter climate is quite mild, and it is said that many invalids live in tents the entire season. Nearly all tourists who journey this way stop over, so that the resort receives much free advertising. A long double-decked bridge crosses the river and railway track here, connecting the town proper on the south side with the springs and park and the great Colorado Hotel on the north side. The whole place is well lighted by electricity at night.

Glenwood Springs is thought to be the first place in Colorado to have a lighting plant operated by water power. The plant was installed more than ten years ago, and has been in constant and successful operation since. The station is on the north bank of the river, just between the vapor cave and the big spring, and the freedom from dust and smoke are quite befitting qualities with such beautiful surroundings. The water supply is taken from "No-name" Creek, at a point 3 or 4 miles distant, giving a head of 380 ft. There are four 36-in. Pelton wheels, operated by single deflecting nozzles, using hand regulation. Each wheel develops 125 HP. at 500 revolutions per minute. There are two 25-K-W. Brush direct-current and one 30-K-W. Brush incandescent lighting machines; also one 30-K-W. Brush alternator and one 60-K-W. Westinghouse alternating arc light generators. 3,000 incandescent lamps and 65 arc lamps are supplied. The lighting machines are belted to the water wheels at 3 or 4 to 1, and the speed of the latter is varied to suit the current desired. The water supply of Glenwood is also furnished by the same company and from the same source.

The distance from Glenwood to Aspen by the Denver & Rio Grande is 41 miles. The railroad runs southeasterly and follows up the Roaring Fork River all the way, traversing a pleasant valley with considerable farming and truck gardening.

Aspen is west of and only 28 miles from Leadville in a direct line, though by the route we have come it is 131 miles. The Aspen Silver mining camp is second only to that of Leadville. The town is situated at the foot of the slope of Aspen Mountain, near the junction of Hunter's, Castle and Maroon creeks with the river. The elevation is 7,775 ft.

The hills surrounding the town are rich with veins of silver, some of which reaches to $1,800 per ton. The Mollie Gibson is said to have been the richest mine in the world, while the Smuggler, Emma, Aspen and others are quite noted.

The Mollie Gibson has paid over $4,000,000 in dividends. The choicest bodies of ore have evidently been worked out, as no dividends have been paid since Jan. 1, 1895. Some of the veins in this mine have been almost pure silver.

Aspen has sadly felt the effect of the fall in silver. The annual production was formerly $8.000,000 to $10,000,000 per year, but in 1897 it was only $3,000.000, or about one-fourth that of the state.

The tributary creeks of the Roaring Fork River afford fine opportunities for the production of water power, which have been fully utilized. The electric lighting of the town and the suply of light and power to many of the mines and mills has been made possible at a very reasonable cost, whereas the use of coal would be quite expensive. There are two companies here producing and supplying electric light and power on a large scale.

I. Roaring Fork Electric Light & Power Co.—This company has two plants, one on Hunter's Creek and one on Castle Creek. The former plant was put in operation in 1889, and was one of the first attempts to operate the machinery in mines and mills by electrical transmission on a scale of any magnitude. Hunter's Creek comes into the river from the east and the power plant is located on the river at the east end of town. Water is diverted from the creek through a covered flume to the face of a mountain overlooking the city, where it is discharged into a wooden tank. From here a steel pipe line 18 to 14 ins. diameter and over a half mile long leads directly down to the power house. The fall is 900 ft., and the working pressure used is about 365 lbs.

The power is developed by eight Pelton water-wheels, 24 ins. diameter, which run at 1,000 revolutions and have a maximum capacity of 175 HP. each. Only six of these are at present in use. The light plant consists of three 30-K-W. Brush arc dynamos, two 100-K-W. Brush incandescent dynamos and three 60-K-W. Westinghouse alternators. There were formerly two Edison power generators, but the use of these and the arc light machines has been discontinued, and only incandescent lighting is done from this station now. When the water supply here is low, a current of electricity is brought over from the company's Castle Creek station, supplying an Edison motor, and thus supplementing the power required. A steam plant for a reserve in case of emergencies is also in place here, but it has not been called on for five of six years. A voltage of 110 is used at the direct current machines, while 1,000 volts are used at the alternating current machines, and this is stepped down to 50 volts at suitable places for lighting. The entire town and many mines and mills are lighted from this station.

The Castle Creek station of this company is located on Castle Creek, at the west end of town. The waters of both Maroon and Castle creeks are utilized. The plant was erected in 1893. Castle Creek is the largest of the creeks, but the water has to be divided with other users. So part of the supply is taken from Maroon Creek, giving a head of 312 ft. The supply from Castle Creek is under a head of 330 ft. This head is obtained within a distance of about a mile, the water being conveyed in a covered flume for part of the way, from the end of which a 24-in. pipe leads down to the station.

The five Pelton wheels are all on one shaft running the length of the bnuilding. These are about 5 ft. in diameter, but vary slightly to give the same speed with the two different heads. About 250 HP. is developed at each wheel. The wheels are provided with friction clutch couplings for operating independently. The speed is 300 revolutions per minute.

There are five 200-K-W. Brush generators driven direct from the main shaft by friction clutch pulleys. The power house is about 50 × 100 ft., giving plenty of room for a convenient arrangement of machinery. This plant distributes power to a number of mines within a radius of 5 miles. The general manager of the company is Mr. C. E. Doolittle, who has made some notable improvements in speed governors for water-wheels.

II. People's Electric Light & Power Co.—The plant of this company is located on Castle Creek, over a mile above the one last mentioned. Water is supplied through a box flume 2½ × 5½ ft. and 2 miles long. This has a fall of 8 ins. per 100 ft. It discharges into a penstock, from which the pressure pipe leads down to the station. This pipe is 3 ft. in diameter at the head and 2 ft. at the foot, and gives a static head of 190 ft. and a working pressure of 80 lbs. The power house has two rooms, the north one containing the machinery for producing power and the south one that for producing light. There are two 5-ft. double 4-in. nozzle Pelton wheels of 300-HP. capacity each, running at 230 revolutions and driving four 100-K-W. Edison generators at 666 revolutions.

For lighting there are two 3-ft. double-nozzle Pelton wheels of 75 HP. each, driving a 60-K-W. Thompson-Houston alternator and a 25-K-W. Thompson-Houston arc light machine. The former is a 1,100 volt, 1,100 light machine, the voltage being reduced to 52 by transformers at certain points. The arc dynamo supplies 50 lights.

Closely allied with the electric company is the Castle Creek Tunnel & Power Co. This company is engaged in driving the Newman tunnel for mining development, the mouth of which is quite near the electric station. Power and light for the prosecution of the work are furnished from the station. A 9-ft. Pelton wheel drives a Norwalk Iron Works air compressor, with cylinders 22 and 16 × 24 ins. They are direct-connected, and the speed varies from 45 or 50 to 80 or 90 revolutions, the capacity being 125 HP. The compressor supplies air to the drills at the face of the tunnel. A small 110-volt machine also supplies light to the tunnel. The face is now about a half mile in. Mr. Geo. S. Newman is president and manager of both companies.

The ARMORED CRUISER "INFANTA MARIA TERESA."

Built at Bilbao, Spain, 1893, by La Sociedad Anonima de Los Astelleros del Nervion. Captured in the Battle of Santiago, July 3, 1898. Wrecked on Cat Island, Bahamas, Nov. 5, 1898.

The water supply of Aspen is furnished by the Castle Creek Water Co., taking water from both Castle and Hunter's creeks. The supply is, of course, all gravity. A pressure of 100 lbs. is obtained from the former creek, and from the latter (the supply of which runs short during low water on account of being used by other powers) it is 125 lbs.

While in Aspen I took a trip into the great tunnel being driven by the Cowenhoven Mine Tunnel & Drainage Co. This tunnel taps a number of mines on its way, besides serving to drain the ground overhead. The parties working the different mines pay so much per car to the tunnel company for hauling their ore out. The minimum charge is $1.25 for low grade ore, and it increases rapidly with the grade or value of the ore. Waste rock is hauled for 25 cts. per car. The cars holds about 3,000 lbs. and 10 are hauled in one train.

The tramway is double-tracked, and rigid rules are enforced regarding the use of it and of the tunnel by the workers in the mines and others. Wherever connection is made with a mine a side track is put in, and the ore is slid down through a chute or brought into the cars on a level, as the case may be. The tunnel is now in nearly 2½ miles. An average of 9 to 11 ft. is driven per day of three shifts. The best record was made last May, when 428 ft. was driven.

Compressed air is supplied to the two air drills at the front by an air compressor plant at the mouth, and incandescent lighting for the tunnel is also supplied. Through all earth and insecure rock the tunnel is timbered with 10 × 10-in. posts and caps. The tunnel falls towards the mouth about 6 ins. per 100 ft., and a box drain between the tracks carries the water drained from the mines. This tunnel when completed will have a length of over 5 miles, and will open into a different valley on the opposite side of the range, whence it is intended to build a railway to a more direct connection with the Denver & Rio Grande main line. W. P. H.

Salt Lake City, Utah, Sept. 1, 1898.

Notes and Queries.

"Common Logarithm," Washington, D. C., will receive a reply to his letter if he sends us his name and address.

F. A. L., Carlyle, Ill., wants the address of a maker of small water motors, which will run steadily under pressures varying from 20 lbs. to 80 lbs. per sq. in., and drive generators for electric lighting.

A correspondent writing from Barnet, England, states that the brief description of the railway accident given on page 241 of our issue of Oct. 20 is incorrect. He states that the accident occurred at Wrawby Junction, near Brigg, some 200 miles from London, and resulted from some timber projecting from a freight train standing on a parallel track.

We have received a letter from Mr. C. F. Petersen, regarding the several formulas for determining the volume enclosed between two intersecting cylinders, published in our issue of Oct. 6. He also replies to the criticism of his formula made by Mr. Thomas in a discussion of these formulas published in the issue of Nov. 10. Mr. Petersen in the original solution which he sent us gave several formulas of different form, and in the communication just mentioned he states that the one selected and printed as his solution of the problem was not the proper one. The letter is too long to publish in full, so we give only the final formula, which he says is correct to within 1 in the third decimal place, and compares very closely with those suggested by Messrs. Baldwin, Comstock, Talbot, Dean and Thomas. The formula is:

$$\text{Volume} = \frac{a^4}{r}\left\{0.393 + \left[\frac{a}{r}\right]^2 0.082\right\}.$$

We regret that the limits of our space and the press of other matters will not permit further presentation of this subject, and we must, therefore, close the discussion with this note.

In connection with the discussion on the relative corrosion of steel and wrought iron, raised by the query of R. S. W. in our issue of Oct. 8, 1898, Mr. Alfred M. Mosscrop, Assoc. M. Am. Soc. C. E., refers the parties to an article in Engineering News, of Nov. 15, 1894, as one of the most complete on this subject. It is an abstract of a paper presented to the Institution of Civil Engineers by Mr. Thomas Andrews, on "The Effect of Stress on the Corrosion of Metals." Mr. Andrews concludes that when wrought iron and various steels are exposed to the action of sea water for a long time, and without liability to other than local galvanic action, the steel showed the greatest corrosion, the wrought iron having an advantage of about 25% in this respect. The corrosion also increased in the steel as the percentage of combined carbon was greater. He also found that galvanic action between wrought iron and steel largely increased the total corrosion in both metals. He also says that stress considerably affects the corrosion, and "unstrained" metal, being softer, is the most liable to corrosion. But the experiments also indicate that the action of local galvanic currents between strained and unstrained parts of a forging, bar, or plate, tends to increase the corrosive action.

THE CAPTURED SPANISH CRUISER "MARIA TERESA."

We show herewith an excellent half-tone view of the cruiser "Maria Teresa," whose unfortunate loss while on her way to the United States we have already recorded. The engraving, which we have reproduced from the "Zeitschrift des Vereines Deutscher Ingenieure," of March 27, 1897, shows the vessel as she appeared when in commission in the Spanish Navy. Her dimensions and general particulars have been so frequently published that we do not repeat them here, further than to note that the armor and armament of the vessel really entitled her to rank as a second-class battleship, and her speed of 20.24 knots attained in a four hours' contract trial in September, 1893, placed her in the front rank in the class of armored cruisers.

* * *

COMPOUND CONSOLIDATION PUSHER ENGINE; LEHIGH VALLEY R. R.

On many railways the profile is such that heavy train loads can be economically hauled over the greater part of the line, but at certain points there are steep grades which would limit the ordinary train load or make it necessary for the trains to be divided at the foot of the grade and taken up in sections. In order to ensure the economy due to the transportation of large train loads, and to avoid delays incident to splitting the trains, powerful pusher engines are frequently employed to help the trains up these grades, and we illustrate this week a large engine of this type recently built for the Lehigh Valley R. R. by the Baldwin Locomotive Works, of Philadelphia, Pa.

It is to run from Coxton to Fairview, 27 miles, without taking water. Its guaranteed hauling capacity is for 1,000 tons of train load behind the tender, at an average speed of 17 miles per hour, on the mountain cut-off.

The engine is of the consolidation type, on the Vauclain four-cylinder compound system, with balanced piston valves. It is fitted with the Wooten firebox for hard coal, the cab being placed at the junction of the boiler barrel and firebox. The dome (with whistle at the side) and sandbox (with air jet device) are mounted on the boiler barrel, while the bell and safety valves are mounted over the firebox. A footboard extends from the cab to the boiler head, and the fireman on the tender deck is sheltered somewhat by a canopy. The crosshead and slides are protected by a casing. The tender is of large size, and is mounted on a pair of Fox pressed steel trucks. The engine is shown in the accompanying cut, and its leading dimensions and particulars are as follows:

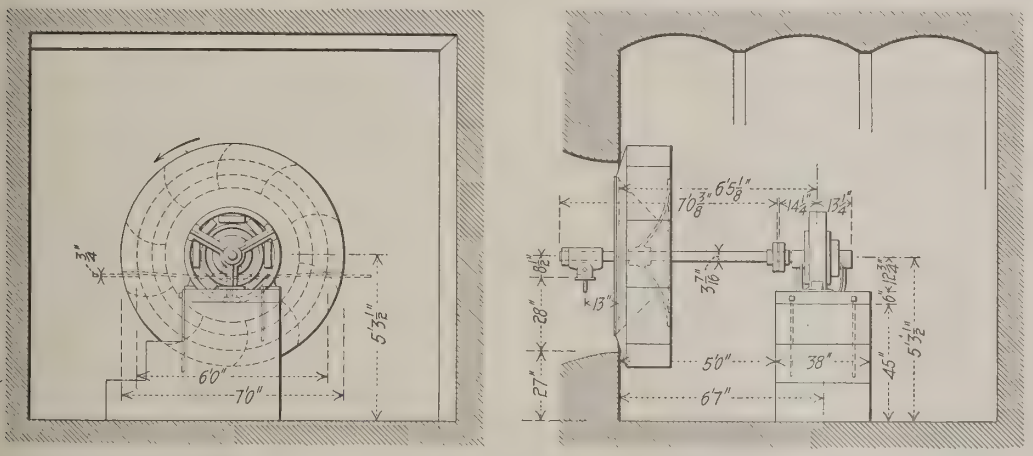
Limit of width	10 ft. 3 ins.
Limit of height	15 " 4 "
Capacity of tender tank	7,000 gallons.

VENTILATION OF THE BOSTON SUBWAY.

We illustrate herewith the method used for ventilating the Boston Subway. The sectional view, Fig. 1, reproduced from the first report of the Boston Transit Commission, 1895, indicates the general arrangement adopted for the two-track portion of the subway. For the four-track portion the fan chamber is larger, containing two fans, and discharging into a stack 11 ft. 6 ins. diameter. The other cuts, showing one of the fans and its attached motor, have been made from drawings furnished by the B. F. Sturtevant Co., Boston, Mass., to whom we are also indebted for the following description:



End Elevation.

Side Elevation.

FIG. 2.—7-FT. VENTILATING FAN, WITH ELECTRIC MOTOR USED IN THE BOSTON SUBWAY.

Designed and Built by B. F. Sturtevant Co., Boston.

In the past the ventilation of railroad tunnels or subways has had for its principal object the removal of smoke and gas discharged by the locomotives employed for traction purposes. But with the advent of electric power and its wide application to street car propulsion, the most important objection to underground transportation has been removed.

Nevertheless, there still remains, as has been clearly demonstrated in the Boston subway, the necessity of a positive and continuous change of air for the double purpose of maintaining its purity and of so regulating its humidity as to prevent the deposition of moisture and the chilling of passengers and employees. This latter feature is of the utmost importance, as is readily shown by the fact that the dew-point of air of 90° F., having a relative humidity of 70%, is about 79° F. That is, if with an external temperature of 90°, there be but a slow and uncertain movement of the air within the subway, it may be readily cooled through 10° or more, thereby become saturated, and not only cause great inconvenience by the constant dripping from all structural work, but become a positive menace to health. A rapid change of air, such as may be secured by mechanical means, serves to equalize the internal and external temperatures, and to prevent the maintenance of a humid atmosphere. At the present time periodical readings of temperature and humidity are being taken under the direction of the Transit Commission, and the results will undoubtedly appear in their forthcoming report.

The original designs of the Boston Transit Commission contemplated the introduction of electrically-driven fans at suitable points along the route. Four of these have already been constructed and installed by the B. F. Sturtevant Co., of Boston, two near West St., and two between Hollis and Eliot Sts. The former location is practically midway between the Boston and Park St. entrances, at each of which there is ample opportunity for the free ingress of air. The space coming under the control of the fans at this point is about 1,050,000 cu. ft. The Hollis and Eliot St. section contains about 900,000 cu. ft.

The fans were, in each case, designed to have a capacity equivalent to an air change in each section once in about 15 minutes. The drawing shows one of the fans at the Hollis and Eliot St. chamber.

The fans are all of the Sturtevant cone type, each consisting of a cast iron conoidal center, with annular back plate of steel attached thereto, and a series of reverse curved steel plate blades or floats, tapering from inlet to periphery, attached to the annular back plate and to the front plate containing the inlet opening. In its course through the fan the direction of the air is gradually changed from axial to radial, the curvature of the blades being such as to offer the least resistance to the passage of the air and to secure the highest efficiency.

The two fans between Hollis and Eliot Sts. are each 7 ft. in diameter, and were designed to each deliver 30,000 cu. ft. of air per minute, when operated at 175 revolutions per minute, and to require an expenditure of about 7 HP. each for their operation under ordinary atmospheric conditions. At one-half the speed the power expenditure would be about 1 HP. Both of those values will naturally vary with the density of the air and the existing temperatures within and without the subway. The two fans near West St. are both 8 ft. in diameter, each designed to deliver 37,000 cu. ft. of air per minute, at 170 revolutions, with a power expenditure of about 10 HP., and to require 1.25 HP. when driven at half speed.

Each fan is provided with an electric motor of special Sturtevant M. P. 8 type, direct-connected to the fan shaft by an insulated coupling. The armatures are of the drum type, thoroughly ventilated and rendered moisture-proof by being saturated in japan and thoroughly baked after having been effectually insulated with mica and oil-cloth. They are shunt wound for maximum speed at 550 volts and arranged for series or a parallel operation, having a starting and regulting resistance giving different speeds for each combination. The maximum temperature rise for 10 hours continuous operation is limited to 45° for the armature, and to 50° for the commutator or fields.

Each motor is mounted on a substantial insulating base frame, constructed of Georgia pine, thoroughly filled to prevent absorption of moisture, and anchor bolted to the concrete foundation.

AN IMPROVEMENT IN RAIL JOINTS.

One of the rail joints of the bridge or base-plate type, which was somewhat extensively used at one time, was the Heath joint, which consisted of one bar forming a base-plate and angle bar and one plain splice bar. The former was stiffened by a vertical pocket stamped down from the middle of the plate. This joint was applied on a considerable mileage of the Atchison, Topeka & Santa Fe Ry., but the results were not satisfactory, and the further use of the joint was abandoned.

The reason for this is stated to have been that the joints were designed by men who were inexprienced as to the requirements of track material, and that the bars did not fit the rails to which they were applied. In the drawing furnished by the railway company, a variation of 1-32-in. from a perfect fit was allowed at both the top and bottom bearing, while these bearings were very narrow. The joints were made according to the drawings, and these conditions are shown in Fig. 1, which represents the joint as made for the 66-lb. rail of the A., T. & S. F. Ry.

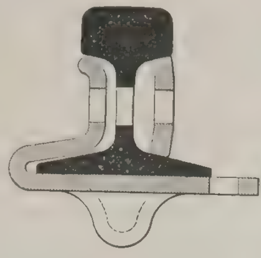


Fig. 1.—Old Heath Rail Joint on 66-lb. Rail; A., T. & S. F. Ry.

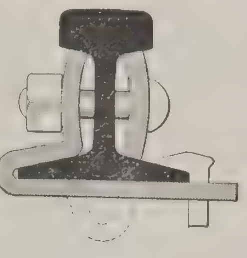

Fig. 2.—New "Common-Sense" Rail Joint on 65-lb. Rail.

This form of joint has recently been re-designed and more carefully manufactured so as to get an exact fit and a wide bearing on both the head and base of the rail. The improved design, as applied to the 65-lb. rail of the so-called Am. Soc. C. E. section, is shown in Fig. 2. The joint is made from boiler plate steel, and forms a bridge support, as well as taking the place of tie-plates on the joint ties, while the plate is made wide enough for spike holes instead of slots; thus acting more surely to prevent creeping. The curved form of the splice bars is claimed to ensure a tight bearing upon the rail and a tight grip of the nut.

The improved form of joint is being introduced by the Common-Sense Rail Joint Co., 304 Tacoma Building, Chicago, Ill., whose factory is at Chicago Heights. For the drawings from which our illustrations are made we are indebted to Mr. W. E. Dorwin, Manager of the company.

THE NEW COAST SURVEY STEAMER "PATHfinder" will be launched at the yard of Lewis Nixon, Elizabethport, N. J., on Dec. 7. This vessel is 196 ft. long over all; 165 ft. long on water line; 33⅓ ft. beam; about 20 ft. deep, and has a displacement of 875 tons. The average speed will be 12 knots, and the boat is especially designed for work in Alaskan waters.

THE SEA-GOING BATTLESHIP "WISCONSIN," to be launched this week by the Union Iron Works, of San Francisco, was contracted for on Sept. 19, 1896, for $2,674,950, for hull and machinery; the keel was laid on Feb. 9, 1897, and the contract calls for completion on Sept. 19, 1899. She is classed as a sea-going coastline battleship, and her general dimensions are as follows: Length on load water-line, 368 ft.; extreme beam, 72 ft. 2½ ins.; mean draft, 23½ ft.; 11,525 tons displacement, and 6,802 tons gross tonnage. She will have twin-screw vertical triple expansion engines of 10,000 I. HP., and a contract speed of 16 knots. Her side armor is 16½ ins. thick at top, tapering to 9½ ins. at the bottom, and 13¾ ins. thick at the water-line; the two turrets are 17 and 15 ins. thick, and the barbettes 15 and 10 ins. thick. The protective deck is 3 ins. thick forward and 4 ins. aft on the slopes, and 2¾ ins. thick on the flat. She will contain 12,464 cu. ft. of corn-pith obdurating material. The main battery includes four 13-in. guns, in two turrets, and 16 6-in. rapid-fire guns. The secondary battery has 16 6-pdr. and four 1-pdr. rapid-fires, one Colt and two machine guns; there will be four Long-Whitehead torpedo tubes. She will carry 40 officers and 449 men. Above the belt-armor she has 5½ ins. of steel protecting the 6-in. gun positions. She is divided into about 300 water-tight compartments, each of which may be separately pumped out, or ventilated by forcing in air; and she has more than 80 auxiliary engines. Bilge keels are provided. The axis of the forward 13-in. guns is 26½ ft., and the after 13-in., 19 ft. above the water surface; the 6-in. guns are from 15 to 22½ ft. above this surface.

THE SUMATRA OIL WELLS are failing, according to a report made by U. S. Consul Everett, at Batavia. The old wells are giving out more quickly than new ones are bored. This state of affairs is said to be due to the conservatism of the Dutch government, which will not permit foreign capital to develop the oil fields, which are among the richest in the world.

ECONOMY TEST OF A UNIQUE FORM OF FEED PUMP.[*]

By F. Meriam Wheeler, M. Soc. N. A. & M. E.[†]

During the past few years considerable attention has been given to the subject of steam economy of the auxiliary machinery on steam vessels, particularly those on warships, where a saving of coal has much to do with the steaming radius of the vessel. Under favorable conditions, as, for instance, in the full power trials of the United States warships, it has been found that in the case of the main feed pumps the average indicated horsepower developed by such pumps is about ½% of the I. HP. of the main engines. I mention this fact to show that feed pumps use more power than any other pumps of a vessel. It will therefore be seen that the feed pump is quite an important auxiliary, and everything should be done to improve its economy in the use of steam. For this reason I have given considerable attention to the subject, and take pleasure in now bringing to the notice of the Society the "economy test of a unique form of feed pump" recently conducted in England, in which the economy was quite remarkable compared with that of the ordinary type of steam pumps usually employed for feeding boilers.

It has been shown by tests that the steam consumption of a feed pump of the duplex type (the one most commonly in use in the vessels of the U.S. Navy) will average about 120 lbs. per I. HP. per hour. In the tests made on the "Minneapolis" the very best economy shown in the case of the main feed pumps was a little over 93 lbs., while the poorest showing was over 200 lbs. per I. HP. per hour. The particular pump my paper refers to did its work with an expenditure of only 52 lbs. of steam per I. HP. per hour, which, considering the fact that it was quite a small unit, is a most excellent showing.

The test referred to was conducted by experts connected with the engineering department at the works of the well-known engine builders, Messrs. Willans & Robinson, at Rugby, England, and was for the benefit of the British Admiralty.

The feed pump tested consisted of a pair of Blake "Simplex" vertical double-acting steam pumps arranged on the cross-compound plan, with h. p. cylinder 6 ins. diameter, l. p. cylinder 9 ins. diameter, two water cylinders 3½ ins. diameter and all 8-in. stroke. The steam is first used in the 6-in. cylinder, and then expanded into the 9-in. cylinder. I desire to call attention to an important feature of this arrangement of pumps in that it has all the advantages of the duplex system, so far as the continuous flow of the water is concerned, and yet either side can be run as a separate pump in case of accident to the other side. Then again, the economy of compounding is secured with but two steam cylinders instead of four, as would be the case of a compound duplex pump. Therefore, there is less loss of steam from cylinder condensation and clearance is reduced to a minimum, as the valve gear of one pump is not operated by the opposite pump, as in the duplex system; consequently, one side can make a full and complete stroke without interference from the other side of pump.

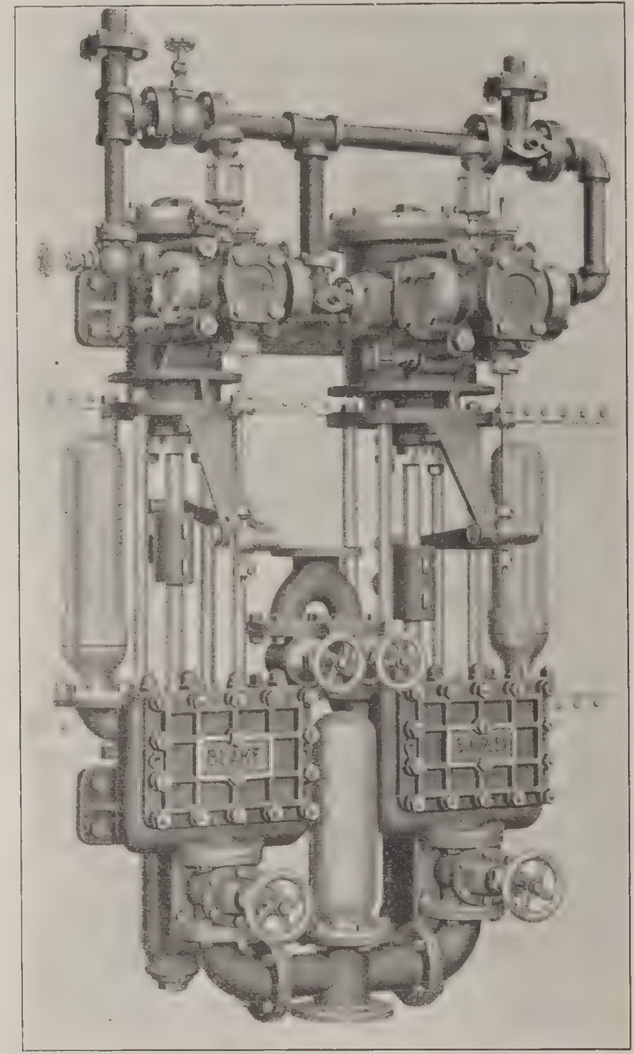

FIG. 2. PERSPECTIVE VIEW OF BLAKE "SIMPLEX" BOILER FEED PUMP.

The Geo. F. Blake Mfg. Co., New York City, Builders.

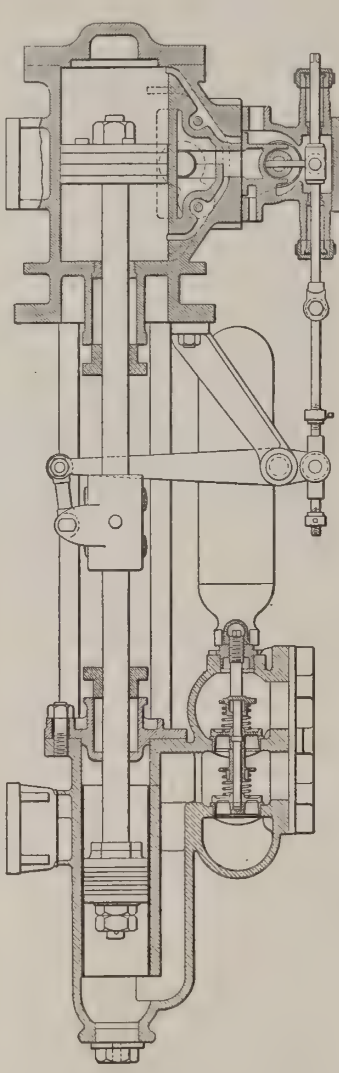

Fig. 2. Vertical Section Through One Side of Blake "Simplex" Boiler Feed Pump, Showing Steam Mechanism.

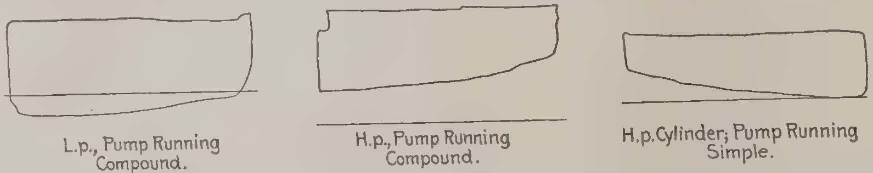

L.p., Pump Running Compound.

H.p., Pump Running Compound.

H.p. Cylinder; Pump Running Simple.

FIG. 3.—INDICATOR DIAGRAMS TAKEN FROM STEAM CYLINDERS; PUMP OPERATING COMPOUND AND SIMPLE.

(h. p. = 120-lb. spring; l. p. = 50-lb. spring.)

Two tests were made: First, by running the pump compound; and, second, by shutting off entirely the low pressure side and running the high pressure side as a simple pump. As mentioned above, the economy of the pumps when running compound was at the rate of 52 lbs. weight of steam per I. HP. per hour, while the economy of the pump running as a simple pump was at the rate of 93.41 lbs. per I. HP. per hour. The following are the particulars:

	Compound.	Simple.
Duration of test, minutes	20.55	28.35
Double strokes per min., each side	40	54
Average length of strokes, ins	8.06	8.05
Initial steam pressure, lbs. per sq. in.	112.5	67.5
Mean steam pressure, lbs. per sq. in. h. p. cyl.	58.06	62.2
" " " " l. p. cyl.	30.28	....
Power developed by h. p. cyl., HP	2.54	3.96
" " l. p. cyl., HP	3.07	....
Total power developed, HP	5.61	....
Total weight of steam used, lbs	100	175
Weight of steam per hour, lbs	292	370
Weight of steam per hour per I. HP., lbs	52.04	93.41

The steam-valve mechanism is very simple, and is shown by the sectional view of the pump herewith. It will be seen that the valve rod (so called) has no valve directly attached to it as is usual; it merely rotates the auxiliary piston, which latter combines within itself the auxiliary valves. This rotating motion is a great advantage, as it frees the auxiliary piston from possibility of sticking for any reason, causing the pump not only to be positive in its action, but securing uniformity of wear. The rolling movement given this auxiliary piston by means of the "valve rod" and the intermediate swinging pin or tongue, opens and closes the auxiliary ports, which, in turn, control the steam to operate the auxiliary piston, moving said piston back and forth across the main steam cylinder. The auxiliary piston, like the main piston, is packed with spring rings.

A plain D slide valve is attached to this auxiliary piston, which valve supplies steam to the main cylinder through the two sets of ports, i. e., the main steam ports and the starting ports. By this cross arrangement of steam chest and valves, the pump can work just as well vertically as horizontally.

As regards the amount of steam that can be saved by this system, there is no doubt but what the pump will save its own weight in coal in 24 hours steaming. With larger size pumps, and with steam pipes covered, the economy of the "Simplex" compound would be even better than that shown in these tests.

Taking the case of a large trans-Atlantic steamer developing 30,000 I. HP., which I understand will be the engine power of the new White Star S. S. "Oceanic," now building, the amount of coal that could be saved on a trip (say, of 5½ days) would be about 77 tons by the use of a system of feed pumps of this cross-compound "Simplex" type, as compared with the simple system of feed pump. This saving in coal not only represents an expenditure of many dollars, but also considerable saving of space which could be made available for cargo or other purposes affording a revenue, thus not only saving money at one end but adding at the other.

---

DYNAMOMETER CAR OF THE C., C., C. & ST. L. RY. AND THE UNIVERSITY OF ILLINOIS.

Among the most important tests made to determine the efficiency of locomotives in actual service are those made by means of a dynamometer car, in which is recorded the actual power exerted by the engine in hauling its train, as well as the various conditions under which the engine is working.

The Department of Mechanical Engineering at the University of Illinois has taken up this matter in connection with the practical training of its students, and has recently equipped a new dynamometer car built by the Cleveland, Cincinnati, Chicago & St. Louis Ry., which will be used in the interests of both the engineering students and the railway company. The car, shown in Fig. 1, resembles a freight caboose car. It is 36 ft. long, mounted on passenger car trucks, and is equipped with M. C. B. couplers and the Westinghouse brake. Its weight is about 36,000 lbs.

While the principal equipment of the car is the automatic apparatus for recording the pull on the drawbar of the locomotive, a number of other appliances have been fitted up in order that road tests of locomotives may be made in a safer and more satisfactory way than when all the observationstions are made on the locomotive. With this car attached, only three observers will be required on the engine, namely: two at the indicator and one at the calorimeter in the cab. In addition to this, the placing of the instruments in the dynamometer car avoids the time and trouble of changing them from one engine to another, while tests can be made of any engine by simply fitting it with the indicator and calorimeter and attaching the car. The instruments can also be more carefully mounted and the readings taken more easily and accurately in this way.

The interior view, Fig. 2, shows the Boyer speed recorder and the Metropolitan recording gage. On the drum of the latter are recorded the strains upon the drawbar. Other instruments are also shown in position. The speed recorder is driven from one of the car axles, in the usual way, and the drum of the recording gage is also driven from the same connection, the clock-work having been removed and suitable reducing gear substituted. Beyond the table, in Fig. 2, against the side of the car, are the 8-in. dynamometer cylinder and its connections, shown in Fig. 3. The piston has cup leather packing, and the piston rod has U-leather packing.

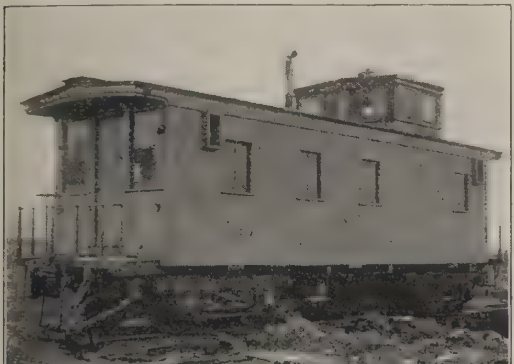

Fig. 1.—Dynamometer Car of the Cleveland, Cincinnati, Chicago & St. Louis Ry. (P. & E. Division), and the University of Illinois.

The cylinder is filled with oil in front of the piston, so that the pull on the drawbar is taken by the oil, and the pressure per square inch is recorded by the gage, which is graduated to 1,000 lbs. The drum of the gage is about 5 ins. diameter, and is removed by the recording arm at different speeds, according to the gearing used. The highest speed so far used is 6 ins. per mile. The second hydraulic gage, which is attached to the same pipe, is graduated so as to give a direct reading of the pull in tons upon the drawbar. We are informed that during a recent test the variation of the recording pen was not over 5 lbs. at speeds above 12 miles per hour. At lower speeds there was more variation, corresponding to the actual conditions, while at the lowest speeds the revolutions of the engine could be counted upon the diagram. A change in the position of the reversing lever or throttle valve makes a noticeable change on the diagram.

When the car is put out of use, the oil in the cylinder is forced back to the elevated storage tank in the corner of the car by admitting air from the auxiliary reservoir of the brake apparatus into the cylinder from above. This is done by the pipes shown in Fig. 3, and any leakage past the piston can be forced into the tank in the same way. When the cylinder is empty, the pull on the drawbar is taken by the draft springs, as usual, the piston then moving nearer the front of the cylinder, but it cannot, under any conditions, strike either end of the cylinder. When the car is to be used for testing, the oil is pumped into the cylinder. The duplex air gage is connected to both train pipe and auxiliary reservoir. In order to prevent any air pressure upon either side of the piston, the two air vent cocks near the globe valves in the air pipes are left open during tests.

While the dynamometer has not yet been calibrated, it is thought that there are but slight losses due to friction. The pointer of the gage moves continually to and fro, slowly and without vibration, and the piston has a continual slight motion, due to variation in the pulling strains and to vibrations of the car. A record is made on the gage even when the dynamometer car alone is being hauled.

The following records are automatically made upon special charts: (1) Boiler pressure; (2) Speed, miles per hour; (3) Pull on the drawbar; (4) Time of passing mile posts. Other records made from observations and readings of the instruments are as follows: (5) Pressure in steam chest; (6) Pounds of water delivered to the boiler; (7) Revolutions of driving wheels per minute; (8) Air pressure in auxiliary reservoir; (9) Air pressure in train pipe. The car will eventually be equipped with electric apparatus, switchboard and signal bells, and arrangements will then be made for recording many other observations on a special chart. These will include the following: (10) Time of taking indicator diagrams; (11) Position of reversing lever; (12) Position of throttle valve; (13) Temperature of escaping gases; (14) Number of weighed bags of coal delivered to the fireman; (15) Direction and velocity of the wind.

The car has been operated on the first division of the Peoria & Eastern Ry. (C., C., C. & St. L. Ry.), between Springfield and Indianapolis, 140 miles, and it is expected that much information of value to the motive power and operating departments will result from the tests. It is soon to be used for making tests with the double-header freight trains between Urbana and Pekin, Ill., 86 miles.

The arranagements for the construction of the car and the conduct of the tests were made by Mr. J. P. Barnard, General Manager of the Peoria & Eastern Division of the Cleveland, Cincinnati, Chicago & St. Louis Ry., and Prof. L. P. Breckenridge, head of the Department of Mechanical Engineering at the University of Illinios. The car was built at the railway company's shops at Urbana, Ill., under the direction of Mr. John McClurg, Division Master Mechanic, and the apparatus was installed under the direction of Asst. Prof. Van Dervoort, of the University.

JOHN WORRALL KEELY.

John W. Keely, whose name has become familiar the world over as the inventor of the so-called Keely Motor, died on Nov. 18 at his home in Philadelphia, after a brief attack of pneumonia. Mr. Keely was over 71 years of age. He was born in Philadelphia (or, according to one account, in Chester, Pa.), Sept. 3, 1827. Little is known concerning his early life, but according to the most reliable accounts, he seems to have drifted from one occupation to another, at one time an upholsterer, at another a druggist's assistant. His first work in the development of the now famous "Motor," according to his own account, was done while he was the leader of an orchestra, and became interested in the subject of the harmony of sounds and sympathetic vibrations.

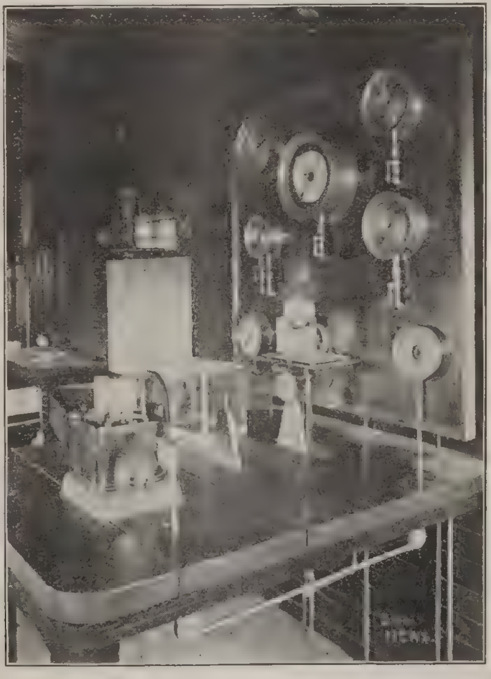

Fig. 2.—Interior of Dynamometer Car Showing Speed Recorder and Gage.

His first invention appears to have been made in the early '70's, and we know little more concerning its nature than that it was exhibited in a bathtub. In 1874 he had completed an apparatus which produced a vapor of great expansive force. This vapor was claimed not to be produced by heat, electricity or chemicals. Exhibitions of this apparatus were made, and were so convincing to those who witnessed them that a corporation known as the Keely Motor Co. was organized with a capitalization of $5,000,000. The stock of the company was rapidly disposed of, and has been bought and sold to a greater or less extent on the exchanges ever since. The stock was never, so far as we can find, offered for sale to the general public, with the accompaniment of a prospectus in the way that most fake enterprises are floated. The principal holders of the stock were those who had visited Keely's workshop and witnessed his demonstrations, and these were generally eager purchasers. Not a few men sunk the better part of their fortunes in the enterprise. The money paid into the treasury of the company appears to have nearly all been expended for the carrying on of the experiments; and in the building of the various machines which were constructed. Mr. Keely, himself, if one may judge by all appearances, lived in the plainest and most frugal style; and the workshop in which all his experiments and exhibitions were made was shabby and comfortless in all its appointments.

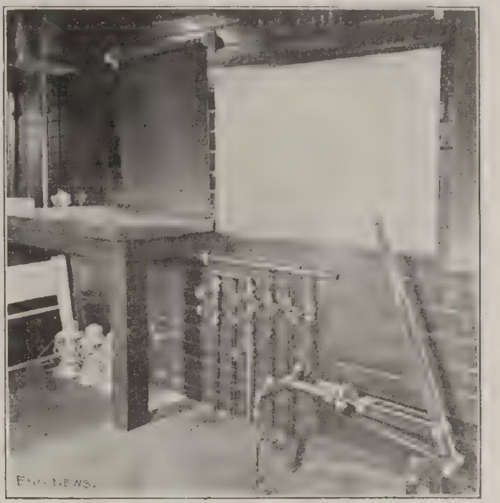

Fig. 3.—Dynamometer Cylinder and Connections.

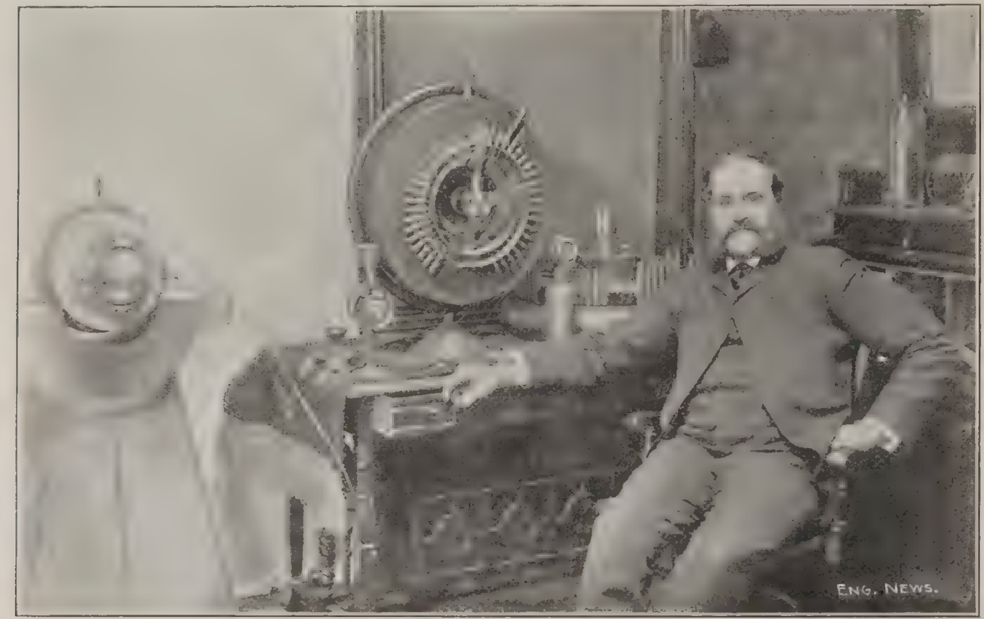
We cannot attempt at this time to describe the work which Mr. Keely did or claimed to do save in the most general way. One misconception concerning it arises from the fact that his invention, if such it may be called, was termed "the Keely Motor." Properly speaking, there is not, and never has been, an actual Keely Motor, meaning by that term a machine adapted to act as a prime mover and develop power for the propulsion of machinery. Certain machines that he has devised have been shown in motion under his hands; but, admitting them to be genuine, they have been nothing more than laboratory exhibits of the crudest order. In fact, the ignis fatuus which Mr. Keely pursued for a quarter of a century, and which he always beheld with unbounded faith only a few weeks or months away, was "a commercial engine." From a personal knowledge of his work extending over a period of nearly ten years, we can say that we have never seen any more than mere possibilities that any of his inventions or discoveries, admitting them to be genuine, would ever possess commercial value, except as discoveries in science. Those who founded the Keely Motor Co., and who stood closest to the inventor all through his quarter century of work, undoubtedly believed otherwise, and Keely himself had the most perfect confidence in his ability alone and unaided to solve every difficulty that stood between him and the long-sought "commercial engine." To those who watched most carefully the various experiments which Mr. Keely performed, however, it seemed clear that if he had, as he claimed, made discoveries of new forces in the ether waves, his knowledge of them was of the vaguest sort, his control over them was uncertain, and their application by him to useful commercial work was in the highest degree improbable.

And now comes the question, were Mr. Keely's experiments and demonstrations genuine? Was the force which set his apparatus in motion produced from heat, electricity or hidden reservoirs of stored energy, by the methods with which modern physicists and mechanics are familiar, or did it, as he claimed, proceed from some hitherto unknown source? To put the question in another way, could another mechanic, using only known physical methods of generating and transmitting power, duplicate his apparatus and accomplish with it the same results?

In the minds of the general public, this question has long been answered, and the "Keely Motor" has been held to be a gigantic fraud, notable chiefly for its long life. Keely's name will undoubtedly go down to history as that of the greatest pseudo-scientific humbug of the nineteenth century. Whether this verdict is a just or an unjust one, the death of the inventor leaves as an unsolved riddle. It is true on the one hand that Keely never, so far as we know, with one possible exception, submitted all the apparatus by which he performed an experiment to such a thorough examination in detail by competent experts, simultaneously with the experiment, as would remove the last possibilities of doubt as to its absolute genuineness and the entire absence of fraud. It is true, on the other hand, that those who witnessed his experiments, and who were competent to judge of them, were almost invariably completely nonplussed and unable to explain the things they saw according to ordinary physical laws. If Mr. Keely performed his experiments by fraudulent means, he was certainly one of the most clever and ingenious mechanics and electricians who ever lived. If he was a genuine discoverer, he lost the fame that might have been his by his eccentric insistence on secrecy, and refusal to submit to investigation. We can, perhaps, sum up the whole matter by saying that Keely's experiments and methods generally had most of the earmarks of a fraud; but it confounded the ablest men who examined his work to tell how it could possibly be accomplished by fraudulent means.



John W. Keely

At some other time we may give our readers in more detail an account of the investigations which have been made by members of the staff of this journal, in endeavoring to solve the mystery of Keely's work. The above, however, summarizes the only conclusions that have been reached.

The accompanying portrait of Mr. Keely, sitting in his workshop, with his peculiar apparatus grouped about him, is reproduced from a photograph taken in 1889, for which we are indebted to the courtesy of Chas. B. Collier, Esq., of Philadelphia, who has been for a quarter of a century Mr. Keely's attorney and intimate associate.

AN ACHIEVEMENT IN CASTING TEST BARS is described by Mr. Thomas D. West in a paper to be read before the Pittsburg Foundrymen's Association on Nov. 28. Mr. West is a member of a committee of the association which is making a most extensive research into the qualities of cast iron. It has prepared patterns for casting 200 test bars of different sizes and shapes, ranging from ½-in. to 4 ins., square and round, half to be made in dry sand and half in green sand. The patterns are to be sent to eleven different foundries, working on different grades of iron. It is most essential that the 200 bars of each cast be made under identical conditions as to quality of iron and temperature of pouring, and these conditions have been secured by the method Mr. West describes in detail in his paper. The molds are all set so as to cast the bars on end, and placed near together in a pit 18 ft. long, 8 ft. wide and 2 ft. 8 ins. deep. Parallel to the main runner on one of the longer sides of the bed, and separated from it by an iron plate placed edgewise, there is a basin, 15 ft. long by 12 ins. deep, made to hold three tons of melted iron. This basin is first filled with metal from the ladle, and then the iron plate is lifted 2½ ins., so as to allow only clean metal to flow into the runner. The success of the arrangement was complete. From the time the inlet plate was lifted until the 200 bars, weighing 3,780 lbs., were all poured, scarcely 20 seconds elapsed, and no bars were lost. This first set of bars was cast at the foundry of the Westinghouse Electric & Mfg. Co., at Wilmerding, Pa.

THE ARCHITECTURAL PLANS for the University of California, under the Phebe Hearst donation, were submitted to an international commission, made up as follows: For France, J. L. Pascal; for Germany, Paul Wallot; for England, R. Norman Shaw; for the United States, Walter Cook; for the University of California, J. B. Reinstein. This commission closed its examination of plans at Antwerp on Oct. 4, and it unanimously admitted to final competition the plans of the following architects and firms: Messrs. Barbaud & E. Bauhain, E. Benard, Paris; Prof. F. Bluntschli, Zurich; D. Despradelles & Stephen Codman, Boston; R. Dick, Vienna; J. H. Freedlander, New York; G Heraud & W. C. Eickmuller, Paris; Howard & Cauldwell, Howells, Stokes & Hornbostel, Lord, Hewlett & Hull, Whitney Warren, all of New York. In addition the commission recommended that the plans of the following architects be purchased for the University: Joanny Bernard & Robert, and Charles des Anges, of Paris; Ernest Flagg, of New York, and Skjold Neckelmann, of Stuttgart. The final meeting will be held in California in June, 1899, and the commission will there select the final plans.

◆

THE NEW WATER TUNNEL AT CHICAGO is again to be the source of litigation between the city and the contractors. The controversy is over the work on Section No. 3 of the land tunnel, the contractors for which are Weir, McKechney & Co. The original contract price of 1895 was $350,080, but up to date the city has paid $592,789, and the work is not yet finished. When Mr. Joseph Downey was Commissioner of Public Works he refused to continue payments for masonry filling in large excavations outside the tunnel section. The contractors took the matter into court, but the Supreme Court decided that they were not entitled to any compensation for excavation or backfilling outside of the tunnel proper. The contractors had, however, been misled to some extent by the profiles and borings furnished by the city, and the court decided that an extra sum must be paid where the excavation was partly in rock and partly in earth. The contract price was $2 per cu. yd. for rock excavation, but after the above court decision an agreement was made for $6 per cu. yd. where both rock and earth were encountered, with $10 per cu. yd. for masonry backfilling. This was approved by the city council, and on this basis the contractors are now endeavoring to claim "extras," while the city claims that much of the work was done purposely with a view to such extras. It is charged that after the proper section had been excavated, inclined drill holes were driven so as to bring down great masses of material above the roof, and to include both rock and earth in the excavation. Affidavits to this effect have been made by the city engineer and his assistants on the work, and by consulting engineers, who have been called in. The city engineer also charges that the directions issued by him and his assistants have been wilfully disregarded by the contractors, and that they have left the work in bad condition, without masonry lining, thus endangering the work and the buildings over the line of the tunnel. After paying several bills the Commissioner of Public Works, Mr. L. E. McGann refused to make any more payments, and on Nov. 10 ordered the work stopped. The contractors at once took the matter to the courts, where it is now being tried.

◆

RIVER GAGINGS IN OHIO are under consideration by the U. S. Geological Survey, and Mr. F. H. Newell, Chief of the Hydrographic Division, has recently visited Columbus to see about the work. Within the past year or so the State Board of Health has made a few gagings on three streams in Ohio.

◆

MUNICIPAL OWNERSHIP of water-works at Topeka, Kan., was decided upon at a special election on Nov. 12. The question was on authorizing the city council to issue bonds to buy or build works. The total vote was light, but the majority in favor of municipal ownership was decided, the vote being 1,703 for and 616 against. Within a few days prior to this action at Topeka, popular votes in favor of municipal ownership were cast at Alliance, O.; Meadville, Pa., and Barrie, Ont. The latter place is also about to establish a municipal electric lighting plant. It is reported that on Nov. 12, the authorities of Pasadena, Cal., and representatives of two water companies which now supply the city agreed on a plan for the purchase of the water-works by the city.

◆

A NEW WATER-WORKS PLANT FOR DENVER has been reported on by Mr. J. B. Hunter, City Engineer. The estimated cost of a large storage reservoir, settling basins, filter beds, supply main and distribution system is $5,700,000. The value of the present plant of the Denver Union Water Co. is estimated by Mr. Hunter at $3,764,000, on the basis of the present cost of duplication, and without allowing for the franchise. The company has offered to sell its property to the city for $9,000,000. The mayor has recommended that steps be taken to provide for an election to vote on $6,000,000 of bonds for buying or building works.

◆

A NEW CROP OF WATER-FILTRATION ORDINANCES is springing up at Philadelphia, three bills having been introduced in the select council the other day. Several more ordinances are promised for Dec. 8. Two of the ordinances provide for contracting for specific systems, and one calls for bids under plans to be furnished by the city.

◆

THE NUMBER OF BACTERIA in London crude sewage is 3,899,000 per cu. cm., at the Barking outfall, and 3,527,000 at the Crossness outfalls, according to the average of a number of recent counts by Dr. A. C. Houston, made early this year, under the direction of Dr. Frank Clowes, Chemist of the London County Council. The range at Barking was from 7,260,000 on May 3, to 513,000 on April 15; and at Crossness, from 5,290,000 on March 2, to 2,410,000 on April 20.

◆

THE ELECTROLYTIC MARINE SALTS CO. dies hard. A committee appointed in August to investigate its affairs has made a report against a receivership, but recommending that a committee of citizens take the company's business in hand, with power to test the Jernegan process for getting gold from sea water, and to disentangle the legal snarl into which affairs have drifted.

◆

A NEW METAL TRACK SIGN now being used to some extent on the Pennsylvania lines, the Missouri Pacific and the Wabash R. R., consists of an angle iron post, set in a section of 8-in. sewer pipe, to which it is secured by braces and a collar on the pipe. The pipe is buried in the ground and filled with concrete or earth well tamped, the bell of the pipe giving a good area for the foundation, so that the post will remain vertical. Sheet iron targets of any desired form or size are riveted to the iron post. These signs are manufactured by the Mathews Woven Wire Fence Co., of Jacksonville, Ill.

THE EQUIPMENT OF THE ARMY, in the late war, is reported upon by Quartermaster-General M. I. Ludington. In 3½ months an army of 275,000 men was uniformed, armed and equipped with supplies, and an army of 16,000 men was sent to Cuba. In the war period the animals purchased cost $3,871,690; wagons and harness cost $358,449, and 83,078 tons of coal were purchased. The movement of troops by rail aggregated 17,863 officers and 435,569 men. The department chartered on the Atlantic coast, to June 30, 43 vessels, with a total of 104,201 tons and these had a carrying capacity of 1,287 officers, 22,335 men, 6,746 animals, and the arms, ammunition and camp subsistence and medical supplies; four water-boats, of a total capacity of 820,000 gallons, tugs and barges were added to this fleet. On the Pacific coast 14 ships were chartered, aggregating 41,152 tons, capable of carrying 629 officers and 13,059 men, and their stores. These vessels cost $186,632 for fitting up; and there was paid for the service of these ships $1,007,952 on the Atlantic side, and $319,764 on the Pacific side. After June 30, other vessels were chartered or purchased, increasing the total tonnage to 111,099 tons, and the carrying capacity to 25,000 men on the Atlantic; and to 61,287 tons and 20,000 men on the Pacific. Fourteen ships, aggregating 61,298 tons, were purchased for $5,431,000; including other vessels and lighters bought, the aggregate expenditure on this account was $6,476,300.

◆

MEDICAL STATISTICS OF THE AMERICAN-SPANISH War, as reported by the Surgeon-General of the U. S. Army, stand as follows: From May to September, inclusive, and representing an army of 167,168 men, there were reported in full 1,715 deaths. Of this number 640 were due to typhoid fever; 97 to malarial fevers, and 363 to diarrhœa and dysentery. The death-rates of May and June—.46 and .70, were not in excess of those of the army in peace times; in July the rate reached 2.15 for the month, or 25.80 per 1,000, which does not much exceed that of well cared for cities. But in August the rate became excessive, or 4.08 per month, or 48.96 per 1,000 per year. In September the conditions improved and the death-rate fell to 2.45, or 29.40 per year. The records of the Civil War show that a high death-rate in August was generally continued for months after, and Dr. Sternberg ascribes the improvement noted in September to the stricter sanitary measures adopted.

◆

THE FIRST VOLUNTEER REGIMENT of Engineers, largely made up of men from New York, arrived from Porto Rico, on the S. S. "Minnewaska," on Nov. 24. In Porto leading to it, at Guanica; it rebuilt many masonry bridges on the military road between Ponce and Albonito, destroyed by the Spaniards; built an ice-making plant at Ponce, and also a water-works system, and did other work of similar character.

◆

FIFTEEN NEW WARSHIPS are asked for by Secretary of the Navy Long, in his annual report. These are classified as follows: Three sea-going battleships of about 13,500 tons trial displacement, estimated at $3,600,000 each, exclusive of guns and armor; three armored cruisers of 12,000 tons trial displacement, esetimated at $4,000,000 each, exclusive of guns and armor; three protected cruisers of 6,000 tons trial displacement, estimated at $2,120,000 each, without guns or armor, and six cruisers of 2,500 tons trial displacement, estimated at $1,141,800 each, exclusive of armor and armament. This fleet would cost over $36,000,000. The Secretary deems these vessels necessary, and he asks that construction be commenced at once. He also recommends to Congress the revival of the grades of Admiral and Vice-Admiral; a new system of rewarding merit and conspicuous service by naval officers; the amalgamation of the line and the engineering staff of the navy; the transfer of all military transport service from the War to the Navy Department; the encouragement of a national naval reserve maintained by federal appropriations; and the addition of 99 officers in the new line of the navy. Of the $29,973,274 appropriated to the Navy, out of the national defense fund, $618,447 remains unexpended. The maximum fighting force of the navy at the close of the war was 196 vessels of all kinds, manned by 24,132 men. The total naval casualties during the war were 17 men killed and 84 wounded; of the latter, 54 went back to duty, and one died of his wounds.

◆

CRUISERS OF MODERATE TONNAGE, with great speed, many guns, but no armor, promise to be a favorite warship of the future. As a direct result of the lessons gained from the Santiago fight, Russia is said to have ordered several 3,000-ton ships with 25-knot speed and heavy guns; and England is reported to be building five 3,000-ton cruisers with 25-knot speeds. The Russian Vice-Admiral Makoroff, head of the navy department, is reported as saying that the Spanish cruisers were provided with well-placed heavy armor, but it could not avert their destruction; they lost the battle because they were lacking in gunners and in guns. Admiral Makoroff argues that with given great speed and heavy armament, four 3,000-ton unarmored cruisers are more advantageous in war than one 15,000-ton ship.

◆

THE FOUR NEW MONITORS, according to plans finally adopted by the Naval Construction Board, on Nov. 23, are to have single turrets, with two 12-in. guns, as originally planned; but will be lengthened 27 ft., giving an added displacement sufficient to permit bunker capacity for 200 tons more of coal. The contractors have agreed to lengthen the vessels for the sum of 103,145 in addition to the original contract price.

◆

THE SHELLS USED BY THE UNITED STATES NAVY, the guns for firing them and the powder charges in each case, are given in the following table:

	Shells.				Guns			Total
Designation.	Diameter, ins.	Wght, lbs.	Length in ins.	Ch'rge contain'd, lbs.	Wght, lbs.-tons.	Lgth in ft.	Firing chrg, lbs.	cost of firing once.
1-pdr.	1⅜	1	3⅝	200*	100	5	...	$1.12
3-pdr.	1⅞	3	6¼	900*	500	7	...	.....
6-pdr.	2³/₁₆	6	8⅝	1,400*	920	9	...	5.70
4-in.	4	33	12¼	2	1½	14	14	....
5-in.	5	50	16¾	3	3⅓	17	30	33.00
6-in.	6	100	20¾	4½	6	21	50	40.00
8-in.	8	250	22⅜	11	15	29	115	65.00
10-in.	10	500	30	20	28	31	240	....
12-in.	12	850	36	40	45	37	425	....
13-in.	13	1,100	42	50	60	40	550	296.00

*Grains.

Note.—For 13-in. armor-piercing projectiles the total cost of firing is $588.00.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred, Nov. 27, on the Boston & Maine R.R., near South Berwick, Me., in which the engineer and fireman of a snowplow engine lost their lives. The plow was being pushed through the heavy snow when it suddenly left the track. The engine followed, going down an embankment and burying the engine crew in the wreck.

◆

A BOILER OF A RIVER STEAMER EXPLODED near Stockton, Cal., on Nov. 27, killing 6 men and injuring 10 others.

◆

SOME AMMUNITION EXPLODED in a house in Havana, Cuba, on Nov. 28, killing or seriously injuring 38 persons. The house contained a considerable quantity of powder, and five rooms filled with obsolete types of cartridges. Those injured were engaged in emptying the cartridges, the intention being to sell the powder.

◆

A LARGE ICE-BREAKER, for use on the Baltic Sea, has been launched in England for the Russian government. The vessel has a bow-propeller, to assist in breaking the ice, and the stern is provided with a recess in which the bow of a ship to be towed can be lashed. This boat is built for the purpose of attempting to keep traffic moving in the Baltic in winter; and besides convoying merchant ships, the breaker can itself carry a large cargo.

◆

ANOTHER OLD CANAL IS TO BE ABANDONED. The Pennsylvania Canal Co., controlled by the Pennsylvania R. R. Co., announces that the consent of the legislature will be asked to the abandonment of the Juniata Division, extending up the Juniata Valley from its junction with the Susquehanna to Newton Hamilton. The entire system of the Pennsylvania Canal Co., 248 miles in extent, carried 250,526 tons in 1897, and earned $59,662. Its operating expenses were $58,405, and the charges for interest and taxes were $151,022. The section which is to be abandoned is a part of the famous old Pennsylvania state canal system and was originally a link in the through line of transportation from Philadelphia to Pittsburg in connection with the old Portage Railroad over the Alleghenies. It was sold by the state to the Pennsylvania R. R. Co. in 1857.

◆

THE PORT ARTHUR CANAL CHANNEL & DOCK CO., says a Beaumont, Tex., item, has received a favorable decision in the Supreme Court of Texas in the injunction suit brought by the property holders near Port Arthur. The decision is claimed to remove all objections to the completion of the ship-canal now under construction, with 4½ miles practically finished. The right to condemn land, under the canal company's charter, was questioned and an injunction was granted by a Jefferson county court.

◆

THE PASS-A-LOUTRE CREVASSE, at the mouth of the Mississippi River, was closed on Nov. 13 by the contractors, Stewart & Co., of St. Louis, after one year's very hard work. The work done was to sheet-pile a length of 7,000 ft. across the Pass. The work was accepted by the U. S. Engineers, and on the next day, a heavy storm caused two breaks—of 102 ft. and 68 ft., respectively—in the eastern wing of the sheet-piling. The loss, amounting to about $8,000, will fall upon the government, but it would have little effect upon the general purpose of the work if these breaks were never closed, as the main body of water is now diverted into the Southwest Pass. The sum of $250,000 was appropriated for the repairs at Pass-a-Loutre; of this sum $195,000 was paid to Stewart & Co., $10,000 was used in surveys of the Southwest Pass, and the balance was practically consumed in incidental expenses. Another appropriation from Congress will thus be needed to close the last breaks.

◆

THE NEW YORK ANTI-TICKET SCALPING law has been declared unconstitutional by the Court of Appeals of that state, which has just handed down a decision in the test case brought by a New York city scalper shortly after the law went into force in 1897. The court's decision is based on an opinion written by Chief Justice Parker, and the court stood four to three in declaring the law unconstitutional. In his opinion Judge Parker says:

> The provisions of the statute in question have reference to the selling of valid tickets, regularly issued by a transportation company. Can the legislature declare such sales to be fraudulent or prohibit them on the ground that it tends to prevent fraud? It is not contended that the business of ticket brokerage is in itself of a fraudulent character. The business can be honestly conducted, and the most that is asserted is that there are some men engaged in the business who have imposed on the public. The same assertion can be made with equal truth of every business, trade and profession. The real motive for the enactment of this law, it is suggested, is to enable transportation companies to keep others with which they may enter into pooling arrangements from secret violation, which is frequently the outcome under the present ticket brokerage system. The granting of monopolies or the exclusive privilege to corporations or persons has been regarded as an invasion of the rights of others to follow a lawful calling and an infringement of personal liberty from the times of the reigns of Elizabeth and James. Argument certainly is not needed in the light of decisions of this court to support the assertion that the "liberty" of this relator (Tyroler) and other citizens of this state to engage in the business of brokerage on passage tickets is sought to be interfered with by the state under consideration; for brokerage in such tickets has been a lawful business for many years. The statute is in contravention of the state constitution, and is void unless its enactment by the legislature constituted a valid exercise of the police power.

As stated the anti-ticket scalping law was passed in 1897, after a hard fight, the scalpers contesting its passage by the legislature at every step. The test case just decided was brought almost immediately after the law went into force. Ticket scalping meanwhile has gone on about as actively in New York city, at least, as before.

◆

TWO NEW FAST EXPRESS TRAINS between New York and Washington, composed of observation, parlor, cafe, smoking and dining cars, the entire equipment being especially made for the service by the Pullman Company, have recently been put in operation by the Baltimore & Ohio R. R. The two trains will leave New York and Washington simultaneously at 3:30 p. m. each day, and they will be exact counterparts in every respect. The parlor cars are 70 ft. long and have 34 seats. They have wide vestibules with anti-telescoping device; empire decks, steam heat, Pintsch gas, air pressure water system, and all modern improvements. The observation, cafe and smoking car is of the same general exterior appearance as the parlor cars, except that the observation end is recessed with a deep platform. The full seating capacity of this car is 33 persons, including 14 chairs in the smoking compartment. All the cars are richly equipped and decorated, and the train will be called the "Royal Limited."

◆

THE PLATINUM PRODUCTION OF RUSSIA, according to Mr. W. R. Holloway, U. S. Consul-General at St. Petersburg, for the year 1897, was over 95% of the entire amount mined in the world, or about 6 tons. Most of this came from the following mines:

Mines of	Count P. P. Shuvaloff	1 ton 396	lbs.
"	Count Demidov San Donato	1 ton 144	"
"	J. Burdakov & Sons	1,512	"
"	Kolly.	1,404	"
"	Andreieff heirs	1,188	"
"	Koenigsberger	1,008	"
"	P. A. Konukhoff	792	"
"	19 small proprietors	1,620	"

EARTH SLIPS ON THE JORDAN LEVEL MARL BEDS OF THE ERIE CANAL.

By Geo. A. Morris.*

Beginning at Otisco or Nine Mile Creek, the Erie Canal for about four miles west runs through low, swampy land, comparatively level and about at the elevation of the present tow-path, making the canal a through cut, 11 ft. deep. At the surface the formation is a covering of muck, and below is found marl over a soft clay, then a cemented gravel. The marl is generally near the surface, but the cemented gravel varies from 2 ft. below surface to 65 ft. below. The valley is narrower at the eastern end (about one-half mile) and widens out on the north side of the canal to about 1½ miles. The old canal followed the foot hills on the south, but on the enlargement the alinement was changed to make long tangents. During the construction of the enlargement three firms of contractors were compelled to abandon their contracts, because of earth slips caused by the subsidence of the marl beds, and the work was finally completed by the State under force account, and after many difficulties had been overcome.

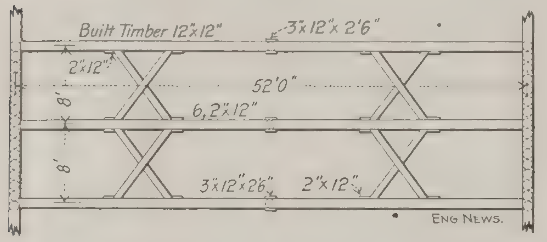

Fig. 1.—Original Method of X-Bracing Struts Across Canal Prism Through Jordan Level Marl Beds.

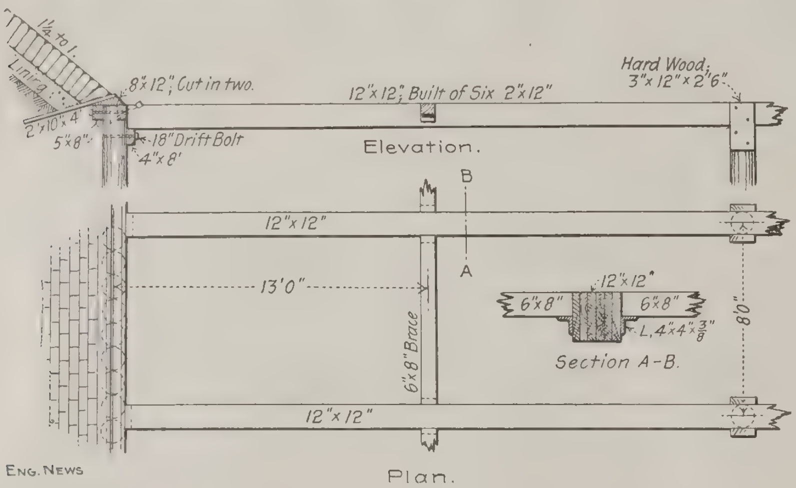

FIG. 2.—ADOPTED METHOD OF BRACING STRUTS ACROSS CANAL PRISM THROUGH JORDAN LEVEL MARL BEDS.

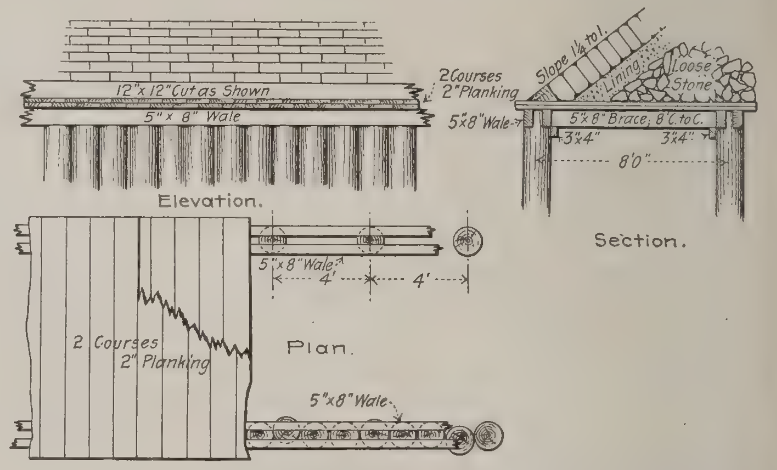

FIG. 3.—METHOD OF UNDERPINNING SLOPE WALL THROUGH JORDAN LEVEL MARL BEDS.

The stratum of marl is of varying thickness, the limit being about 15 ft. The following table gives the elevation of the top of the marl as actually shown from cross-section notes, datum being 1 ft. below the new canal bottom.

Station 208 = + 10 Station 240 = + 6 Station 410 = + 10
Station 220 = + 12 Station 368 = + 10 Station 420 = + 8
Station 238 = + 14 Station 380 = + 13

The marl and clay can be readily handled when dry, but when wet the mixture weighs from 80 to 83 lbs. per cu. ft. An excellent quality of Portland cement is made from equal parts of marl and clay by the semi-humid process. The "Engineering Record" of July 16, 1898, has the following analysis of this material as it is used by the Empire Portland Cement Co.:

	Per cent. Marl.	Per cent. Clay.		Per cent. Marl.	Per cent. Clay.
Si O_2	0.26	40.48	Mg O Co_2....	0.38	0.99
Al_2 O_3, Fe_2 O_3	0.10	20.95	Loss, ignition.	4.64	8.50
Ca O Co_2....	94.39	25.80			

As the elevation of surface of the water during navigation is 2 ft. lower than the tow-path and the latter is about on the level of the swamp, the canal necessarily had to take all the drainage. When the contractors commenced to excavate in the prism they built coffer-dams across the channel at short intervals and diked the sides, then used powerful steam pumps to drain their work. When the pressure from the sides was removed, the pressure from above would raise the material in the bottom (similar to squeezing paint from a paint tube) and it was soon discovered that more material was being removed than was shown on the cross-sections and that the slope walls were sliding into the canal and that the berme and tow-path banks were settling. Immediately it became necessary to devise means for stopping the sides and to confine the material. Various plans were suggested, but they all carried a considerable expense with them. Different methods that were economical in design were tried, each taking time to try the experiment. Piles were driven 8 ft. c. to c. with waling piece and sheet piling, then 4 ft. c. to c., then a close row of piles, but the piles would not enter into the cemented gravel, and as the material had become thoroughly saturated, they would lean over into the canal and occasionally would pop up out of the ground (Fig. 4). It was finally decided to abandon the attempt for that season and to drive a close row of piles during the season of navigation, then when the water was drawn in the fall, to put on a waling piece to start the slope on, and to build only a short stretch at a time. This course was adopted. The piles were driven during the summer, but as the piles did not penetrate into the cemented gravel, and the material around the piles was in solution, it was soon discovered that we would have to resort to an original and expensive plan and place struts across the canal, as shown in the accompanying plans. We found that the method of X-bracing (Fig. 1) was expensive and that the brace at right angles to the strut (Fig. 2) would answer. The latter was adopted. The plan as finally adopted proved very successful and was used for 3,700 ft. of canal in one place and 500 ft. in another.

The greatest difficulty was encountered between Stations 370 and 410, and occupied our attention during both closed seasons, but during the first season the adjoining swamps were full of water. During the season of 1898 a drainage ditch was made on both sides of the canal, emptying into Nine Mile Creek at the east end and White Bottom Creek at the west end. This ditch took all surface drainage, so that the only water in the canal was from percolation, which was considerable. Because of this drainage ditch about two miles of slope wall was built on both sides of the canal without using struts, but with only a close row of piles with a waling piece to start the wall upon (Fig. 3). This portion had formerly caused the most trouble and cost the most to build, and we had anticipated that it would be the most difficult to handle. But inside of two months the prism was excavated to grade and two miles of full depth wall built on both sides. This work was prosecuted by digging the excavation trench for the waling piece, putting the waling piece in place, and building the wall ahead of the prism excavation. Another advantage this work had in its favor was that it was done in the latter part of March, April, and the first of May.

The difficulties encountered on this section of the canal were so many and varied, that it is difficult to describe them in general, for the reason that until the struts were used all we had done proved unsuccessful in the aggregate, although quite a number of the plans used proved successful under certain conditions. A severe cold winter, instead of a very mild one, would probably have eliminated any of the difficulties, and the work would have been done wihout any additional cost or without any one being aware that there was a suspicion of what actually did occur.

In one of the photographs sent with this article (the photograph is too dim for engraving.—Ed.) is shown a pile with the head very near to the bottom of a 30 ft. pile-driver. The piles used for a long distance either side of this point were 42 ft. long. In describing the driving of this pile, I will state that what is true of this one is also true of all the others. When this pile was raised the head was 12 ft. or more above the top of the leads. As soon as the fastenings were removed, the pile settled with its own weight into the marl until its head was below the top of the leads. A small rope was fastened to the pile and two men pulled it down to where the hammer could be placed upon it, and with simply the weight of the hammer it settled to where it is shown in the photograph. A light blow drove it to the cemented gravel layer. There was a crust a few inches thick over this layer which the pile could be driven through, but which then became so hard that great care had to be taken not to hit the pile too heavy a blow, as it was liable to break it, or throw it out of line, and a pile out of line could not be forced back. The only remedy was to pull it and redrive it. Some of the piles that were driven to resistance have lifted to the extent of 8 or 10 ft., as shown by Fig. 4, which also shows how they would move bodily into the canal. Just before the opening of navigation in 1897, the tow-path in stretches from 500 ft. to 1,500 ft. in length settled anywhere from 2 ft. to 8 ft., and in all cases where it broke away from the main land it was a vertical fracture.

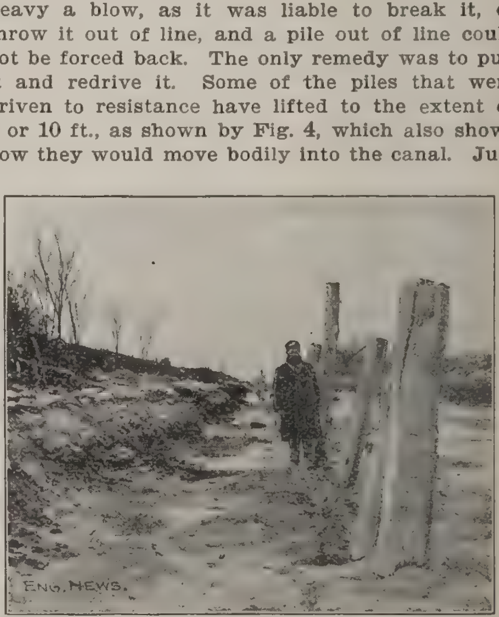

Fig. 4.—View Showing Manner in which Piles Rose and Tipped After Driving, Jordan Level Marl Beds.

At Newport Bridge we encountered a difficult

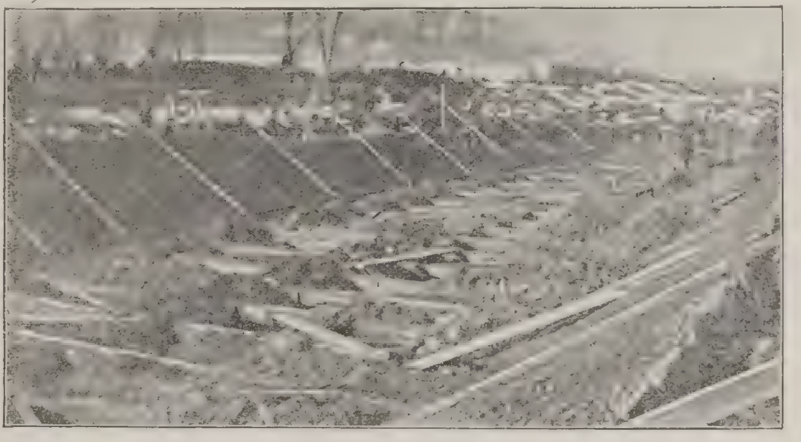

FIG. 6.—VIEW OF CANAL PRISM, SHOWING BOTTOM BRACES IN PLACE AND SLOPE WALLS UNDER CONSTRUCTION.

problem in rebuilding the abutments, vertical wall on tow-path side and slope wall on berme. Before the bottom courses of the old abutment on the berme had been removed in winter of 1896-'97, great fissures were discovered running either side of the excavation. We removed all of the excavated material from the bank and drove piles at the foot of the slope wall, but the fissures extended and the banks began to settle, the wall sliding toward the canal and pushing the piles we had driven with it. Great cracks exhibited themselves in the foundation to Dwyer's Hotel. We drove piles 50 ft. long as near to the hotel as the pile-driver could approach it, but they moved bodily toward the canal.

Under the foundation to the berme abutment piles 57 ft. long were driven with two courses of 12×12-in. hemlock foundation timbers securely fastened on them. On this the masonry was built. Cinders were used as back filling. When the back filling was about half completed the abutment moved bodily into the canal about 3 ft. and settled about 6 ins. It is supposed that the bottom of the piles remained stationary, and that the tops leaned all together, as the abutment did not move on the timber foundation and did not get out of line. As the bridge was in place when the abutment moved, the parapet walls on both abutments were destroyed. We immediately put four struts across the canal between the foundation of the berme abutment and the vertical wall on the tow-path side and below canal bottom. These struts remained until this spring.

The slope wall, however, kept sliding into the canal and finally laid flat. Two close rows of piles were driven 6 ft. apart, capped and floored with two courses of 3-in. plank, to make a foundation to start the wall. The embankment to build the wall upon was made of loose stone and coarse gravel from 4 ft. to 16 ft. back. Even with this precaution the wall would settle in one place and push out in another, and was rebuilt the second time in March and April, 1897, and in December about 300 ft. of the upper 4 or 5 ft. had to be relaid.

The vertical wall on the tow-path side kept settling all summer, and notices had to be put up cautioning the boats to keep on the berme, as the wall as it settled on top would raise on the bottom. In order to maintain the tow-path the contractors kept adding stringers and filling in with cinders during the whole season of navigation. In Fig. 5 it will be seen how much the wall settled below the tow-path. It was, of course, necessary to rebuild this piece of wall. Great vertical fissures developed running parallel to the tow-path, which kept growing wider, and the ground for 150 ft. each side of the bridge settled, in some places 2 ft., for 30 ft. back. We began the foundation and wall at the point furthest away from the bridge and worked toward it, meeting under the strut. Struts were used across and under the canal between the foundations of the vertical and slope walls, and between abutment and vertical wall.

The cost of this work is, of course, known, but whether it would benefit the public or not is a question not easily answered. The contract prices were used in paying for everything that could be measured. As there was no known way of ascertaining the amount of excavation, it had to be done under a force account. The cost of redriving piles, rebuilding foundations and walls, rehandling of all kinds of material, building runways and coffer-dams, keeping ditches open, and the many other items too numerous to mention or remember, all went toward the aggregate cost. The contract prices were reasonable, being as follows:

Excavation, cts., per cu. yd.	27½
Embankment, cts., per cu. yd.	30
Lining, per cu. yd.	$1 00
Piles, delivered and driven, cts., per lin. ft.	18 to 25
Hemlock timber, per M. ft., B. M.	$16.00
Spruce timber, per M. ft. B. M.	$17 00
Bridge abutment masonry, per cu. yd.	$7.00
Vertical wall in Portland cement, per cu. yd.	$5.00
Slope wall, per sq. yd.	$2.47
Portland cement concrete, per cu. yd.	$5.00

There was a deduction for all material found in the work that could be used. Mr. M. B. Palmer, of Clinton, N. Y., was the Assistant Engineer in charge of the work for about a year, and then Mr. Wm. B. Landreth, M. Am. Soc. C. E., of Cortland, N. Y., was in charge for nine months, or until the contract was completed.

COMPOUND ENGINE IN THE POWER-HOUSE OF THE BUDAPEST ELECTRIC RAILWAY.

(With full-page plate.)

The stationary engine illustrated in our insert sheet is one of three which are in use in Budapest, Hungary, in the power-house which furnishes current to the electric street railways and the underground railway. It was designed and built by L. Lang, of Budapest. The "Zeitschrift der Vereines Deutscher Ingenieure," from which we reproduce our cut gives a very brief description of the engine, from which we take the following:

The engine has its cylinders arranged on the Collmann system, which affects the balancing of the reciprocating parts, the two cranks being set at 180°. A vertical engine of similar construction was in operation at the Electro-Technical Exhibition at Frankfort in 1891. The diameters of the cylinders are 18 and 32 ins., the stroke is 33 ins. The normal speed is 135 revolutions per minute; this number can be varied 6% either way. The high pressure cylinder is fitted with the Collmann valve gear.

An inspection of the cut shows that this engine possesses many features that are quite novel to most American readers. Among them we notice especially the following: The fly-wheel is "dished" like a cart wheel, apparently with the object of getting its center of gravity closer to the bearing than is the case with the common wheel. The cylinders are placed neither tandem nor alongside, but in echelon, the high pressure cylinder being both forward of the low pressure cylinder and alongside of the piston-rod of the latter. With the cranks at 180° this arrangement is more compact than the cross-compound plan, at the same time making it possible to balance the reciprocating forces and to divide the work between two cranks, which cannot be done with the ordinary tandem engine, although it is very successfully done with the Wells balanced compound engine, which has two tandem cylinders, the low pressure piston having two piston rods, the high pressure cylinder lying between them. The valves on the high pressure cylinder are of the poppet valve type, controlled by a fly-ball governor, and multiported slide valves are used on the low pressure cylinder. Each cylinder has four valves, and all the valves are driven from eccentrics carried by a secondary shaft, which is driven by a miter-gear from the main shaft.

While the engine is no doubt well designed, and embodies many good ideas, it is likely to impress an American engine builder as being very complex and costly for a moderate sized stationary engine, only 18 and 32 ins. × 23 ins. stroke, and he will probably doubt the need of balancing such an engine, as to its reciprocating parts, when it is run at a piston speed of only 518 ft. per minute.

A HANDY INSULATOR FOR JOINTS IN WIRE.

We illustrate herewith a novelty in the way of an insulator for use in connection with railway motors, or in fact wherever the common brass sleeve screw coupling is used to splice wires. At present whenever a motor is removed from the truck, for repair or any other purpose, the insulating tape which has previously been carefully wound about these screw couplings has to be cut and thrown away. This entails the use of new tape, and as there are from four to six such connections for each motor, the time consumed is also quite an item. The device here illustrated consists of a tube oval in section, composed of semi-hard rubber, which is slipped over the screw coupling, and two flexible end caps which hug the wire and close down into grooves in the oval shell, as will be seen in the figure, thus making a sightly, safe and watertight joint which can be very quickly put on or removed, and can be used over and over again. The cost of this device is less than taping, and its advantages as a time saver will be only too apparent to those who have taped screw-coupled joints. This insulator is manufactured by the Methuen Electrical Co., Methuen, Mass.

THE NORTHEAST WATER TUNNEL AT CHICAGO was completed Nov. 21 by the contractors, Messrs. Fitz Simons & Connell. The land sections of the tunnel, known as the northwest land tunnel, are not yet completed, and there is litigation pending over this part of the work. The lake section will, however, probably be used during the winter, as the intake crib has been specially designed with a view to preventing trouble from ice.

RECENT IMPROVEMENTS IN CENTRIFUGAL PUMPS.

By J. Richards.*

The writer in 1896 was called upon to prepare designs of pumps for the great drainage plant, or plants, at New Orleans, and after a careful examination of the various means, other than centrifugal pumps, for raising and impelling large and variable volumes of water, came to the conclusion that the conditions, including the relative efficiency of different methods, made the use of centrifugal pumps preferable. This opinion was shared by Mr. Charles Brown, C. E., of Basle, Switzerland, who acted as my colleague, and who is, perhaps, the most eminent authority in such matters that can be referred to.

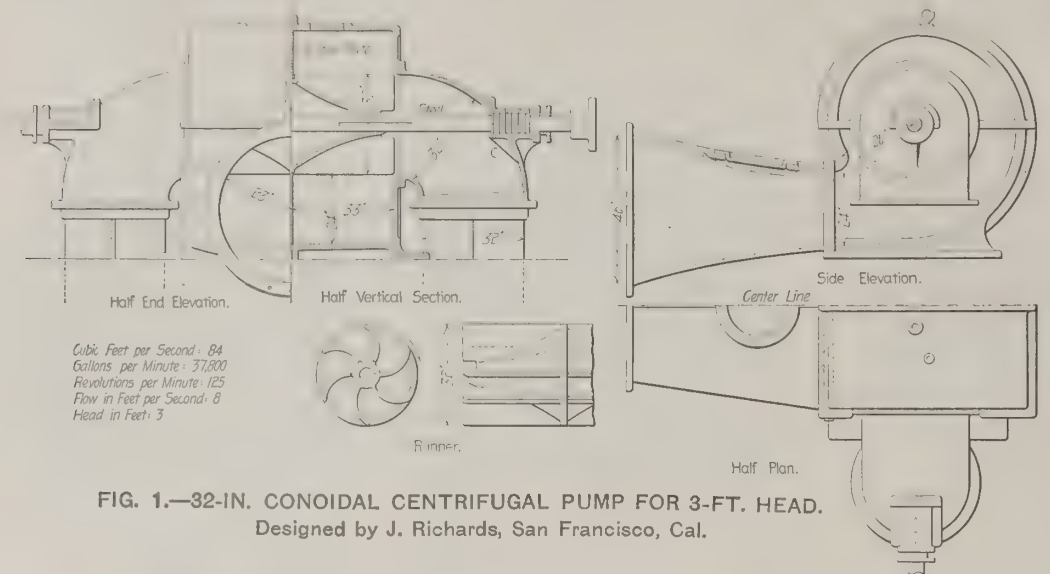

FIG. 1.—32-IN. CONOIDAL CENTRIFUGAL PUMP FOR 3-FT. HEAD.
Designed by J. Richards, San Francisco, Cal.

The power to impel the pumps at the various stations, scattered over the city and on the line of outfall, was in most cases to be transmitted by wires from a central power station and applied by electric motors, and therein arose a serious impediment in the adaptation of the speed of the pumps to that of the electric motors to drive them. A large number of motors were required, aggregating, as now remembered, over 7,000 HP., and the economic limitations of the speed or rate of revolution for the motors was such that the pumps had to be adapted accordingly.

As the proper circumferential speed of centrifugal pumps differs only in a slight degree from the velocity due to the head, being about $8.5 \sqrt{H}$, in feet per second, and as the head in some cases was only a few feet, pumps constructed on the ordinary lines were out of the question. The impellers to produce the required speed became less in diameter than the suction pipes to convey the water at a velocity of 8 ft. per second.

This difficulty led to the adoption of the "Conoidal" system which it is the purpose of this article to explain. The name "conoidal" was applied by Hon. Henry H. Bates, of Washington, D. C., and relates especially to the impellers, as will be explained hereafter.

Reverting further to the designs of the pumps for the drainage works at New Orleans, these were prepared under the impression that the machinery could not be submerged. Fig. 1 represents a pump to raise 84 cu. ft. per second, or 37,800 gallons per minute under a head of 3 ft., the pump and motor making 125 revolutions per minute.

The drawing with the dimensions given make the construction so clear that no explanation is required except in respect to the impeller. This, it will be seen, is a double conoidal spindle, provided with the usual vanes. It is buoyant in the water to the extent of its displacement, which about equals its weight, thus relieving the pump shaft from the pressure due to the weight. It will also be seen that the conoidal form distributes the work equally over the width of the impeller from the inlet to the center, completely changing the course of all the water before it reaches the center. To provide against any possible lateral disturbance around the impeller, a diaphragm (a) is introduced so that the two sides of the pump will operate independently and balance the thrust on the shaft.

The impeller is of the same diameter as the bore of the pipes, and the vanes have, in this case, no entering curves because the field of the water's revolution extends back into the suction pipes to some distance not yet determined by experiment. The discharge way was a rectangular parallelogram 66 by 24 ins., as shown in the drawing. The pump illustrated is of average size, many of them being larger.

After preparing the designs for the New Orleans draining plant, I proceeded to investigate this system of constructing centrifugal pumps, not only in respect to their being driven by electric motors, but for all purposes to which such pumps are applied. This investigation led to the development of tables for proportions so as to bring the design of the pumps as nearly as possible within an organized system of manufacture.

Fig. 2 is a drawing to scale of a conoidal pump of 10 ins. bore, or discharge, adapted to average conditions for heads from 10 to 50 ft., but as modification for the various heads is required in order to attain full efficiency, the tables referred to had not only to include constant dimensions and quantities, but also variations therefrom. The system is about to be subjected at San Francisco to regular trials for efficiency, the results of which will in due course be published. The letters on the drawing refer to tabulated dimensions.

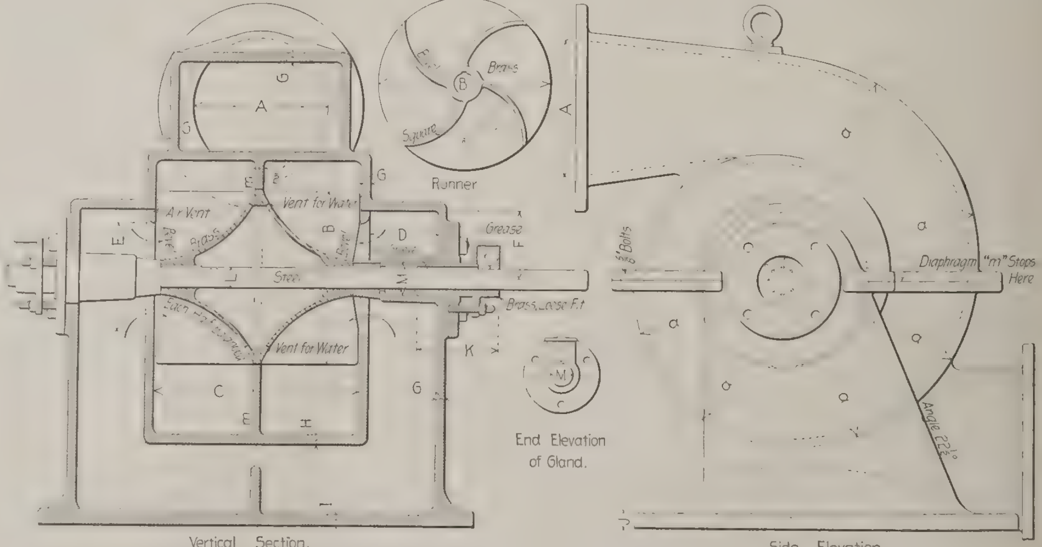

FIG. 2.—CONOIDAL PUMP FOR HEADS FROM 10 TO 50 FT.

Fig. 3 is an elevation of a conoidal centrifugal pump erected for pumping from a ditch or river, and gives the contour and appearance, which is quite uniform for pumps from 5 to 60 ins. bore.

The most important conditions in centrifugal pumping are the efficiency, endurance, and first cost, and as may be seen by examination of the drawings, the two last-named features have due recognition in the present system. Endurance can be inferred from construction, but the calculation of cost is more intricate. It may be explained from some rules of common application. For example: The relative dimensions, weight and cost of a rotative machine of almost any class or type, are inversely as the speed of revolution. The cost of centrifugal pumps is roughly as the square of their extreme dimensions; that is, a pump standing 6 ft. above its base will cost four times as much as one that measures 3 ft. above its base, and so on. By these rules it may be seen that the conoidal system will greatly diminish the cost of pumps for a given volume of water, because their dimensions are in most respects reduced inversely as the rate of rotation.

The technical features affecting efficiency could be discussed here, but as a good deal may be disclosed by experiment, this part of the subject will be laid over for a future article.

THE GEOGRAPHIC WORK OF THE COAST AND GEODETIC SURVEY.

By John F. Hayford,* Assoc. M. Am. Soc. C. E.

(With full-page plate.)

The United States Coast Survey first became permanent in 1832, although the original act providing for a survey of the coast and making an appropriation for that purpose was passed in 1807. A formal reorganization took place in 1843. In it the plans for the survey which had been formulated and acted upon in former years by F. R Hassler, the first Superintendent, were continued in force. The scientific organization of the Survey may, therefore, be properly said to date from 1832. The survey was to be made primarily for the benefit of commerce, was to extend twenty leagues from shore, and special observations were authorized even beyond that limit, as far as the Gulf Stream, when in the opinion of the President such observations might be especially valuable to the commercial interests of the United States.

In the course of time the Coast Survey proved to be an organization of such vigor, its results proved to be so uniformly trustworthy, and there were found among its officers men of such acknowledged ability, that the scope of its duties was gradually but steadily widened to include a great variety of operations allied in various ways to its original duty. Now, after a little more than a half century of activity, the Survey finds itself rendering more valuable benefits to commerce, by way of making the navigation of the coasts safe, than ever before; and also finds itself actively engaged in many other forms of geographic work.

The requirements of the original acts of organization of the Survey might, perhaps, be considered to be fulfilled when accurate charts of all parts of the coast had been made. This, the fundamental work of the Survey has been carried on vigorously and steadily. Commencing with a few of the more important regions on the Atlantic coast the work of chart making was gradually extended until the charts now cover (although the original surveys do not) every part of the Atlantic, Gulf and Pacific coasts of the United States, and a large portion of the Alaskan coast. From time to time, as the interests of commerce demanded, the surveys in certain special localities and important harbors have been repeated in greater detail, and the new information embodied in new charts—often of larger scale than before. Meanwhile the commercial interests involved have increased to such an extent that the demand for surveys for charting purposes is as great as ever, resurveys in greater detail in some regions and original surveys in regions where the charts now depend upon compiled data.

*Expert Computer and Geodesist, U. S. C. & G. S., Washington, D. C.

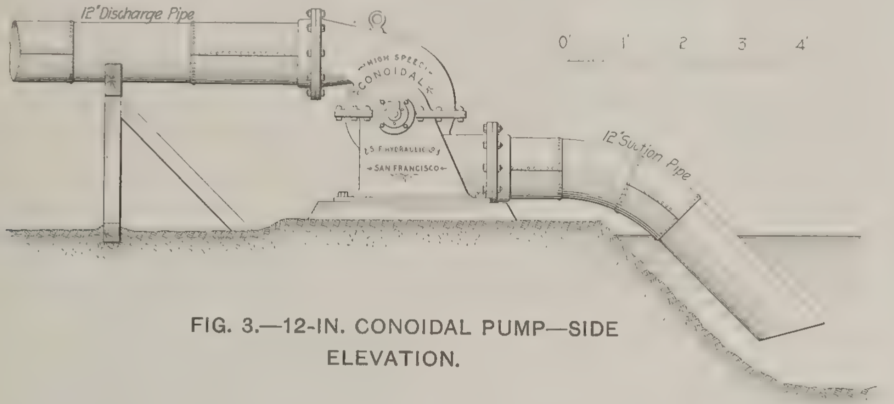

FIG. 3.—12-IN. CONOIDAL PUMP—SIDE ELEVATION.

The Survey at present issues over 500 different charts and maps varying in scale and character according to the objects for which they are designed. Nearly all of them belong to one of four general classes, viz.; 1st, sailing charts, on a scale of 1-1,200,000, which exhibit the approaches to a large extent of coast, give the offshore soundings, and enable the navigator to identify his position as he approaches from the open sea; 2d, general charts of the coast, on scales of 1-400,000 and 1-200,000, intended especially for coastwise navigation, and showing the configuration of the shore, the positions of islands, rocks, and shoals, the light-houses, life-saving stations, and other natural and artificial landmarks; 3d, coast charts, on a scale of 1-80,000, by means of which the navigator is enabled to avail himself of the channels for entering the larger bays and harbors, and to recognize the beacons, buoys and light-houses by their distinctive features and positions; 4th, harbor charts, on large scales, intended to meet the needs of local navigation. The work of the Coast Survey is closely co-ordinated to that of the Light-House Board, and all changes in lights, beacons, or buoys, are promptly indicated upon the charts by correcting them up to date by hand entries at the last moment before they leave the office. The charts, except certain editions classed as preliminary, are printed at the Survey office from copper plates made by the Survey's corps of expert engravers. They will stand the closest scrutiny as to the accuracy and neatness of work upon them as well as to the reliability of the information which they furnish. That the mariner appreciates these charts is indicated by his demand in ordinary times for 25,000 of them per year, at a cost to him of about $11,000. Another 25,000 or more are distributed annually to various departments of the government and to libraries.

The Coast Survey charts are a reliable basis upon which to design proposed harbor improvements, and they have been extensively so used by the Corps of Engineers of the Army. In those cases in which one or more resurveys of a harbor have been made the charts are of unusual value in this connection, for the changes observed to have taken place in the intervals between surveys serve to indicate what changes must be guarded against in the future, and what favorable changes may be relied upon, and to indicate the probable effect of proposed structures upon depths in their vicinity.

The officers of the Survey have made accurate topographic surveys of 38,000 square miles, mainly in connection with the work of making charts.

In addition to the charts the Survey now issues the "Coast Pilot" in nine quarto volumes, and other volumes are now being prepared. The "Coast Pilots" are issued for the same purpose as the charts, to conduce to safety in navigation. They give, in elaborate detail, descriptions from the mariner's point of view of the coast, of the shores of harbors, of the character of available anchorages, and of the known dangers to navigation, together with sailing directions for entering harbors. The volumes are illustrated by views of portions of the coast which may serve as landmarks, and by portions of charts.

When considering the contributions of the Coast Survey to geographic science, it should be kept in mind that its charts and "Coast Pilots" are in the main the results of original surveys and observations, made by its own officers, the data compiled from other sources forming but a small proportion of the whole. These original surveys have, as a matter of course, brought to light hundreds of shoals, banks, sunken rocks and other dangers to navigation which were before unknown. In several cases they have also incidentally made known unsuspected safe channels for entering harbors. The main ship channel now used in entering New York harbor was discovered by a Coast Survey party during its regular operations at a time when a much poorer channel was in use and was supposed to be the best. A Coast Survey party operating at the mouth of the Yukon during the past summer discovered a new channel carrying a depth of 8 ft. across the bar at low water. This channel will save much time and distance, and a trans-shipment, for vessels of sufficiently light draft to use it.

A study of the tides forms an essential part of the work of charting a coast. Along this line the Coast Survey has been particularly active, both in taking observations and in making tidal predictions. Over one hundred stations have been occupied with self-recording continuous-record gages, and the total length of such record is equivalent to a continuous record for more than three hundred years at a single station. In addition to this, short series of readings have been taken from staff or box gages at 2,500 different stations. Based upon these observations upon our own coasts and upon the compiled results of observations upon foreign coasts, the Survey publishes annual volumes of tidal predictions for the whole world. The volume for 1899 shows the predicted time and height of every high and low water throughout the year for 24 stations in the United States and for 46 foreign stations. These primary predictions are based upon a harmonic analysis of records from self-recording gages. In those cases in former years in which the predictions have been carefully compared with the actual tides as subsequently observed, the discrepancies developed have been so small that it is probable that they were due almost entirely to meteorological causes. These primary predictions are extended to about 3,000 secondary stations, with various degrees of accuracy, by means of tidal differences and ratios derived from short series of observations at those stations.

The shores of the ocean, and the bottom near the shore, are continually being modified by the action of waves, currents and winds. The Survey has rendered important service both to geographic science and to commerce by carefully noting such changes in certain localities, and by noting the mode of operation of the causes which produced them. The safety and efficiency of public works for the improvement of harbors often depend upon an accurate conception of these causes.

One of the most interesting problems of physical hydrography is that presented by the Gulf Stream. What explanation can be given for the existence of this great current of unusually warm and salty water; apparently acting as one of the controlling factors in the climate over an ocean and upon the coasts of two continents; seemingly resistless in its motion, and yet so sensitive to disturbing forces that in its current the varying effect of the moon's attraction has been detected? Through the observations made by the Survey the status of this problem has been greatly changed. Formerly it was easy to find a theory which would seem to explain the few observed facts, and accordingly many theories were extant and unrefuted. Now, such an abundance of facts are on record that none of the old theories seem to be adequate, and no satisfactory new theory has presented itself. The scientific world seems in this matter to be in a healthy state which is prophetic of true progress, viz., it is realized that while the facts so far established are sufficient to prevent unqualified acceptance of any extant theory, many more observations are necessary to satisfactorily refute old theories or establish a new one. The principal facts which have been established by the Survey depend upon soundings along the track of the stream and in the Gulf and Caribbean Sea; numerous and accurate observations of the density and temperature of the water at a great many points at all depths in the stream and the Gulf, serving to show the vertical as well as the horizontal distribution of these elements; and finally, observations of the current itself. The current observations are remarkable for the fact that they have been extended to great depths, never before explored by a current meter.

The mariner relies to such an extent upon the magnetic needle that a study of terrestrial magnetism is a necessity in connection with the duty of chartering the coasts. In harbors a knowledge of the dip and intensity is needed, as well as of the declination, in connection with the process of adjusting ship's compasses. Nearly all of the early, and many of the modern, surveys in this country having for their purpose the fixing of property lines were made with the compass, and therefore an accurate knowledge of the geographical distribution and secular changes of the magnetic declination in the interior of the country is of great practical value as a means of preventing and settling property disputes. The determination of the magnetic declination for the purposes of the mariner at various points along the coast formed the small beginning from which has developed a great magnetic survey which covers the whole country and which has proved to be of great scientific as well as practical value.

The operations of this magnetic survey may conveniently be classified as, 1st, magnetic observations by the officers of the Coast and Geodetic Survey; 2d, the compilation of results obtained by outside parties; 3d, the systematic correlation, discussion, and publication of the accumulated data.

Officers of the Coast and Geodetic Survey have made magnetic observations at some 1,200 stations distributed over the whole country (a few also in foreign countries), and many of these stations have been reoccupied several times with a view to determining the secular changes and to keeping the magnetic information up to date. Continuous series of observation have also been made at five stations (usually with self-recording instruments) covering a period of several years at each. These observations, together with those compiled from other sources, have served to determine the geographical distribution of the magnetic declination, dip, horizontal and total intensity for the whole United States, and a more or less extensive knowledge of their secular variations at many stations. The declination, which it is most desirable to know for practical purposes, has been determined at 3,500 stations, and there are 118 stations at which its secular variation has been determined by observations at 13 widely separated epochs on an average. The series of appendices to the annual reports, in which the carefully digested results have been published from time to time, form an unrivaled repository of magnetic information pertaining to the United States. Assistant C. A. Schott, the author of this series, had recently been awarded a prize of 5,000 francs ($1,000) by the French Academy as a recognition of the scientific value of his researches in terrestrial magnetism.

From the beginning, the surveys of the coast were based upon triangulation of a secondary and tertiary order in the immediate vicinity of the hydrographic and topographic operations. The desirability of an adequate control over this coast work when it extended over great distances led to the execution of primary triangulation extending some distance inland. Later, as the desirability of connecting the Atlantic and Pacific surveys became evident, and as it also became evident that inland triangulation was of value to the states traversed by it and to various inland interests, the transcontinental triangulation was projected, the Coast Survey was directed to furnish accurate geographic positions to the several states, and the name of the organization was officially changed from Coast Survey to Coast and Geodetic Survey (in 1878).

At the present time the triangulation covers an area of 350,000 square miles and determines accurately the geographic positions (latitudes and longitudes) of nearly 29,000 points. See full-page illustration showing areas covered by completed triangulation, together with reconnoissance and proposed triangulation. The elevations of 2,800 of the triangulation stations have been determined by measured vertical angles. In connection with the triangulation, over 5,000 miles of precise leveling has been done, and this serves to fix the elevations of more than 1,000 permanent bench marks, and to control the elevations derived in part from trigonometric leveling.

A geodetic survey is geographic work on its grandest scale, for it furnishes a measurement of the earth as a whole, even though the area covered by the survey may be but a small portion of the earth's surface. Aside from two other short arcs (8° in aggregate length) the Coast and Geodetic Survey has now nearly complete an oblique arc from Calais, Me., to Fort Morgan, Ala., 22° of a great circle or 1,500 statute miles in length, and an arc of the 39th parallel 48½° or 2,600 statute miles in length. These four arcs have an aggregate length measured on a great circle of 57°, whereas the combined length of the available arcs (measured by various nations) used by Clarke (in 1880) in deriving the figure of the earth was 82°. Evidently the United States is an *active* member of the International Geodetic Association. It is also noteworthy that the different Coast and Geodetic Survey arcs are all connected so as to form a single system, and therefore have greater weight, or efficiency, in the determination of the earth's figure and size than they would have if disconnected.

The figure and size of the earth are derived from the results of a triangulation by comparing the geodetic latitudes, longitudes and azimuths with the astronomical values of those quantities as directly observed. On the oblique arc, 14 telegraphic longitudes, 48 azimuths, and 61 latitudes have been observed; while on the transcontinental (39th parallel) arc the numbers are 35 telegraphic longitudes, 73 azimuths, and 109 latitudes. A few of these determinations are common to the two arcs.

The study of the station errors developed when these astronomic measures are compared with the geodetic measures also furnishes an interesting contact point between geodesy and dynamic geology, for the limiting magnitude of the station errors is a measure of the strength of the earth's crust—if it is permissible to use the word "crust" in the present state of our knowledge. Geologists have shown that in the past there have been immense quantities of material transported in various ways to considerable distances along the earth's surfaces, by glacial action and the action of running water, for example. Such transfers of material must produce stresses in the rigid (?) earth and must also produce station errors, the distribution of matter being changed from what it must have been when the whole globe was made up of fluids and the station errors were each zero. In those cases in which the transportation is continuously in one direction, as for example, that caused by running water, the stresses and the station errors must go on increasing indefinitely unless there is a yielding on the part of the rigid (?) earth. Any yielding and counter transference of material beneath the surface must reduce both the stresses and the station errors. The station errors furnish, therefore, a measure of the accumulated amount of transportation in those regions in which such amount is small; and furnish a measure of the strength of the material composing the earth in those regions in which the accumulated amount of surface transportation is very large and the station errors and stresses have both been reduced by yielding until the stresses could be borne by the material.

The formation of the great telegraphic longitude net, covering the United States and spanning the Atlantic, is a geographic feat worthy of especial note. This great net comprises no less than four transatlantic telegraphic determinations (1866, 1870, 1872, 1892), serving to connect the longitude system of this country with Greenwich and Paris. The whole system, including the European connection, is composed of 45 stations connected by 72 determinations of difference of longitude. The average value, without regard to sign, of the corrections to the separate determinations arising from the least square adjustment of this great net is only one-fiftieth of a second of time, and the maximum value is $0.^{s}069$ (to a determination in 1866). The probable error of an adjusted longitude difference is $\pm 0.^{s}024$.

In that grandest of geographic undertakings, the measurement of the earth as a whole, another method of attack is by the use of the pendulum for the measurement of gravity at various points upon the earth's surface. The activity of the Coast and Geodetic Survey along this line may be inferred from the fact that its observers have occupied over 60 home stations and 28 foreign stations.

The importance of a geodetic survey can not be properly judged by the number of points directly established by it. It bears the same relation to other surveys covering the same territory that the Supreme Court does to lower courts. Its results are of such a high degree of accuracy that it stands in the position of a court of last resort among surveys; it serves to prevent too great an accumulation of error in other surveys; to decide as to the right when two or more determinations by different surveys disagree; and to furnish indisputable points of departure for new surveys. It is in this relation to other surveys that the great geographic value of a geodetic survey lies. To the geodetic survey must properly be ascribed a part of the value of every survey based upon or controlled by it.

The relations of the Geodetic Survey of the United States to other surveys may be illustrated by a few instances taken almost at random. The Massachusetts State Survey, serving among other purposes to fix the township boundaries, is based upon the work of the national geodetic survey; two of the latest municipal surveys, that of Baltimore and that of the Borough of the Bronx* (a part of Greater New York), are based upon and controlled by the geodetic work of the Coast and Geodetic Survey; the topographic work of the United States Geological Survey is based upon triangulation by the Coast and Geodetic Survey in the regions covered by their triangulation; disputed portions of many of the state boundaries have been finally fixed by the Coast and Geodetic Survey. Among the latter cases, and within the last ten years, may be mentioned the oblique portion of the California-Nevada boundary now being located and marked after years of disputes and resurveys by various parties; a portion of the Maryland-Virginia line; the north boundary of Delaware; and the Indiana-Ohio boundary. The surveys on the part of the United States in connection with the disputed Alaskan boundary have been made by the Coast and Geodetic Survey.

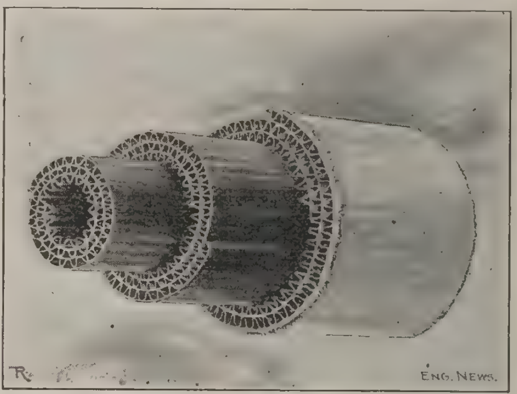
AN AIR CELL PIPE COVERING.

The pipe covering shown in the accompanying illustration, known as the "Gast Air Cell Covering," is designed to insulate effectually ammonia or brine pipes. It consists of corrugated and flat sheets of light straw board made up together in the form of split tubes. In placing the covering, after the pipe is clean and perfectly dry, the first section is sprung about the pipe, drawn tight, and the flap cemented down with paste or glue. The second and third sections are placed in the same way, except that each is slipped back, as shown in the cut, so that joints are broken. The total thickness of the covering for pipes up to 1½ ins. is 1½-in.; above this 2 ins. is used. The coverings are made in 3-ft. sections, the outer one having a canvas cover. In making elbows, tees and short bends a special filler with molded covers is used.



Corrugated Paper Insulating Covering for Pipes.

The peculiar construction forms a series of small air cells, one overlapping the other, the whole precluding the outside air from gaining access to the pipe. In this way no moisture can reach the pipe, and the formation of frost or ice on its exterior is, therefore, impossible. At the same time the circulating liquid is practically unaffected by temperature changes of the atmosphere or surrounding objects. The covering is also recommended for protecting water pipes from freezing in cold weather. It is made in sizes to fit ½-in. to 8-in. pipe, the former costing about 40 cts. per ft. and the latter $1.25 per ft., when in place; the other sizes ranging between these limits. The New York Fireproof Covering Co., 26 Cortlandt St., New York city, are the manufacturers. A steam pipe covering employing the same principle, using, however, asbestos paper instead of the corrugated straw board, is manufactured by the same company.

THE TRAINING AND WORK OF THE ENGINEER.*

By Chas. Wallace Hunt, Pres. Am. Soc. M. E.

A change has been taking place of late years in the work required of professional engineers. This has largely come from the development of our manufacturing establishments from the position of being a minor factor in our economic life, to being one of great importance, and the necessary employment of skilled engineers to conduct their technical affairs.

The engineer of the user and the engineer of the maker have widely different duties. Consider how different may be the information required in practice by two classmates, whom we will designate as "A" and "B," who graduate from college as engineers. "A" secures a position in the engineering department of a city, and commences his work, which may be the designing of a new water pumping station. His college course has fitted him for the work. His text-books were suited to problems of this character. He finds abundant information on all branches of the subject in data published in the proceedings of scientific societies, in technical literature, and in annual reports of city departments. The forms of contracts to be entered into are at hand, all found elaborately drawn, with every point safeguarded, and need only a little selection and adaptation to suit his case. They place in his hands the power to decide absolutely and without appeal all questions which may arise in carrying out the work.

* Port Angeles closed, station moved to Port Crescent, 10 miles distant.

"B" obtains employment in the engineering department of a manufacturing corporation, which in due time estimates and submit tenders for the pumping plant for which "A" has issued specifications. He will find that the form of contract proposed by "A" has many minute and carefully worded clauses to bind and limit the supplier. The tender to be submitted for the work must in its scope and wording protect the interests which "B" represents not only in a general sense, but in every one of the clauses of the proposed contract. Every obscure phrase and every adjective used by "A" must have definite consideration and be clearly defined in both an engineering and legal sense. "B" here finds that the information derived from his college course is largely inapplicable, and there is no technical literature which he can use, either as a general guide for making a form of tender or the proper expressions to use to define or limit the obscure clauses or words found in the specification.

Looking at the subject from a purely technical point of view, we see quite as great a variation in their work. "A" would require only a general knowledge, while "B" would require the most thorough and exhaustive information of the qualities of constructive materials, and shop practice available in that particular location. The farther we carry the comparison of their work, the more clearly it is seen that the educational requirements are becoming more complex to correspond with the growing specialization of engineering work.

Engineering Practice Abroad.

There is another phase in engineering practice represented by the duties of "A" and "B" which now becomes interesting if the work of American engineers is to take the place in the world at large to which the indications now so plainly point. In other countries it is a common practice for "A" to make all the general designs and all of the details, and the supplier has no responsiblity either for the design or for the efficient working of the plant when completed. If errors or omissions are found in the drawings or specifications, the cost of the changes required are paid by the purchaser, in the usual bill for extra work. In this case the duties of "B" are small or disappear altogether.

American Engineering Practice.

The American practice is tending to the method of making the requirements issued by "A" of a general character which will cover the results sought, and leave to the supplier, 'B," the work of designing the particular means to accomplish the desired end. Business has become of such a magnitude, and so complex that one mind cannot fully grasp, and readily handle, the new discoveries, new materials and new practices, which now come so rapidly. For efficient and economical results, each phase must be handled by an expert. There will be many "B" engineers to respond to the requirements of "A," and each will present for consideration different ideas, different materials, and different shop practices. "A" must select from these various plans and details submitted, the one which best promises to fulfill the requirements. It is a division of labor between "A" and "B," each of whom, by tastes and training, is especially fitted for his part of the work. We may paraphrase their duties by saying that "A" is a judge, "B" is a counsellor.

Post-Graduate Needs.

At the present time we cannot expect our technical schools, painstaking and perfect as they are, to prepare both "A" and "B" fully for such new and varied duties, or even to have their instruction in the practice of engineering fully abreast with the latest practice, or at least not until progress in the arts and sciences has substantially ceased. It takes time for a new practice or a new result to be recorded, published, considered, and adopted by the teaching staff. This difference between the teaching and the engineering practice of the day is not only an indication of progress in engineering, but in some measure an index of its rate. The student then must expect, as a normal proceeding, to supplement his graduating acquirements by further study, together with association with his professional brethren, in order to place himself abreast of the times, and to be fitted for the most effective and useful service.

Engineering theory and practice are rapidly extending with the general advancement of our economic interests, and the engineer, whether he be a young graduate or otherwise, who does not make use of the modern aids to information, among which are to be counted scientific societies and literature, and a personal association with his brethren, with the innumerable hints and suggestions which come from these, will soon be found struggling with what seems to him adverse fate, but what, in reality, is inferior knowledge, behindhand knowledge; or, plainly speaking, ignorance greater or less. The engineering world has passed by him, and he must then view the working out of the law of the survival of the fittest, with what grace he may.

The advance made in the accumulation of useful data and more accurate knowledge in practical engineering gained one season, is presented to a scientific society the next, and still later it will be embodied in text books for the instruction of students who are soon to take our places and carry on our work. Until attention is called to the subject, we are not likely to realize that in their essential parts the great bulk of the engineering data available to us now have been first presented to a scientific society, and there permanently preserved until the time came for their utilization or application. It is from this great fund of information, principally accumulated during the last century, that we draw upon for the materials for our textbooks, our general treatises, and our engineering handbooks.

Scientific associations aim to add to the great fund of information available to every engineer the world over, and not for the benefit of a limited clientage. The greater the availability and the publicity given to the published proceedings of a scientific society, the more nearly has the society accomplished the chief object of its existence.

Industrial Progress.

It has long been evident that we are making rapid progress in perfecting our manufacturing machinery, as well as organizing and developing our industries, thus constantly increasing the efficiency of our labor, until we have lately reached a point where an hour's labor with its facilities produced more of our principal products, and transported them further, than an hour's labor would do in any other part of the world.

Commencing under adverse conditions and developing in a field of restricted capital, with scarce and high-priced labor, engineering in America has applied the forces and materials of nature to the uses of man in a characteristic way. Freedom from mediæval traditions and the hampering conditions found in the older countries, left them substantially free in the choice of means to accomplish their end. Influenced as our engineering has been by the experience and the work of other parts of the world, yet we cannot escape the fact that its development was essentially independent, and in some phases unique. Improvement has followed improvement in technical matters, profits and savings have been added to the capital invested in our industries until the continent, two hundred years ago an untraversed wilderness—one hundred years ago a struggling nation—struggling with industrial difficulties and serious political problems—has triumphed over these early limitations, and has developed into a nation which, in numbers, prosperity, and wealth takes a prominent position among the great nations of the world.

Effect on the Mind and Character.

The life of the engineer has a full measure of the labors, the trials, the discomforts, and the disappointments which are found in this, as in every other walk of life. But it also has the successes which come from well-directed labors. It is not, however, either the useful work or the successes of life which bring happiness. It is man's ideals which make him happy.

Whichever way engineering may develop as time rolls on, its elevating influences are constantly at work on the mind and on the character. The work is carried on under unchangeable laws, which must be rigorously applied and adhered to, or failure is sure to result. Man builds to master, to resist, or to guide the forces of nature. If he has rightly judged the conditions, his work stands as a permanent monument of the fact; but if otherwise, the irresistible laws of nature will develop the defect and discover his ignorance, incompetence, or error to every observer.

Hence he laboriously seeks out the unseen laws and forces, then expresses the revelation in a workable form for his daily use. He tests his materials with painstaking refinement. He measures electric resistances with an accuracy now reaching the point of one in four millions, time to the one three-millionth part of a unit, divides a circle with a mean error not exceeding the one-millionth of the circumference, makes surfaces 6 ins. square with a variation from absolute flatness of less than one-two hundred thousandth of an inch, rules lines which vary from absolutely perfect spacing by only one-three millionth part of an inch, sees clearly the spectrum of samarium when one part is diluted with three million parts of lime, and surveys lines 11 miles long in the open air with an average variation in three measurements of only four-tenths of an inch.

The Basis of Ethics.

The effect of living and working in such a sphere of action, where it is inconceivable that an engineer could knowingly be otherwise than exact in his work, should tend to influence the whole trend of his life and character, and makes them to a greater or less degree a reflex of his daily work. He of all men has the most unchangeable and exalted basis for his ethics—the clearest of all knowledge of the disastrous results which will surely follow the violation of law. The very qualities of his mind which makes his work a pleasure and a success will all tend to bring his every act into compliance with the inexorable laws of the universe. If it is otherwise, and his conduct is not guided by the laws of right doing and right thinking, and his ethics not in accordance with them, then, and to that extent, he is not an engineer—not one who is skilled in the application of the forces of nature to the uses of man.

THE METHOD OF ERECTING EGYPTIAN OBELISKS has long puzzled the student of Egyptian antiquities, and the numerous documents and wall-pictures found do not explain it. In a late issue of "Construction Moderne," Mr. J. C. Kruseman suggests a possible method of handling blocks of stone weighing as much as 1,000 tons, and sometimes 131 ft. high and 10 ft. square at the base. These blocks were also placed on pedestals considerably raised above the actual level of the soil. Mr. Kruseman finds that these obelisks were generally placed in front of pylons or temples. He believes that the Egyptians first built a slightly inclined causeway of sand or other material, equal in height at one end to the obelisk to be erected; ending at the end in a strong wooden crib, and leaving a space between the crib and the temple for the obelisk. The base was then built and the space between the temple and the crib was about half filled with sand; and on the face of the crib a strong inclined chute was constructed leading to the base. The obelisk was then rolled up the incline on hard wooden rollers; and, with tackle leading to the temple, it was then allowed to tilt over the front of the crib, falling into the sand and guided by the chute. By slowly and carefully digging away the sand and hauling on the top of the obelisk it would thus be gradually sunk, until it would finally rest on its base.

A VENEZUELAN EXPOSITION, of natural, agricultural and manufactured products and works of art, will be held at Caracas, from Jan. 1 to April 27, 1900. The exposition is also to include methods of education, social economy, hygiene, public charity, colonization, etc.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; 6 *months,* $2.50; 2 *months,* $1.00. *To all other countries in the Postal Union: Regular Edition, One Year,* $7 60 (31 *shillings*); *Thin Paper Edition, One Year,* $6.31 (26 *shillings*). *SINGLE COPIES of any number in current year,* 15 *cents.*

In ordering changes of mailing addresses, state BOTH old and new addresses; notice of change should reach us by Tuesday to be effective for the issue of the current week. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 *means that subscription is paid to the 32d week (that is the issue of Aug.* 11) *of the year* 1898; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want noticees, special rates, see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

The greatest discrepancy between the engineer's estimates and the actual expenditure in the work upon the Erie Canal Improvement under the $9,000,000 appropriation occurred on Contract No. 4 of the Middle Division, located on the Jordan level of the canal. According to the Canal Investigating Commission, the bid on which this contract was awarded amounted to $154,471 at the quantities named in the preliminary estimate. Up to May 1, 1898, the State had expended $581,879 on this contract.

The difficulties encountered in carrying on the work on this contract, and the methods tried for overcoming them are described on another page of this issue by Mr. Geo. A. Morris, Resident Engineer of the Middle Division of the Erie Canal. The difficulties of building and maintaining embankments upon deep beds of soft material such as bogs and marshes are pretty well known to most engineers; but so little has been done in canal construction during the present generation that many engineers have forgotten probably that it is even more difficult to dig and maintain a water-carrying ditch through a bog than to build an embankment across it.

It is of interest to note that the sliding banks on the Jordan Level of the Erie Canal were closely paralleled by the heavy slides on the new Soulanges Canal in Canada, which occurred a year ago (Oct. 26, 1897). The latter were much greater in extent and occurred suddenly, while the earth movements on the Jordan Level were comparatively slow. Both, however, are examples of the difficulties involved in canal excavation through certain soils, especially when saturated with water. It is proper also to point out at this time when engineers are engaged on estimates for such important works as the canals at Nicaragua and Panama, and from the Great Lakes to the ocean, that the difficulty in making and maintaining canal excavations through the troublesome materials above referred to increases rapidly with the depths which the excavation must reach. Abundant experience was had, in fact, at Panama, in the excavation of the sea-level section through the marshes on the Atlantic side, with the difficulties in economical ditch digging under such conditions. One huge Slaven dredge is said to have worked at one time for several weeks without moving from her position, the weight of the mud which she discharged upon the banks continually crowding in the banks and raising the bottom as fast as the material was excavated.

◆

It sounds like the boom times of a dozen years ago to read that the United States Commissioner of Railroads proposes that the Government shall construct "a first-class, double-track air-line railway," from Kansas City, Mo., to San Diego, Cal. Probably most readers will be puzzled to know who and what the U. S. Commissioner of Railroads may be. The public and all railway men are fairly familiar with the Interstate Commerce Commission; but not one in ten thousand, probably, knows anything about the Commissioner of Railroads. We may explain, then, that he is an appendage of the Interior Department, and his duties appear to consist in watching to see that the government-aided Pacific railroads meet their obligations to the Government—and drawing his pay. Since the Union Pacific was reorganized, and the Government's lien was wiped out, the Commissioner's time seems to have hung heavily on his hands, and we presume he has hatched this scheme for a Government railway to amuse his leisure hours. To do him perfect justice we will give the substance of his argument for the enterprise in his own words:

> The annexation of the Hawaiian islands, and the probable control of the Philippine and Ladrone islands, must open up new trade relations of such growing proportions with them as to so materially increase the business of all the bond-aided roads that it is within the scope of reason to anticipate their ability at an early date to pay principal and interest of their debt to the United States.
>
> The vast volumes of wheat and other cereals which now find their way from the middle-western grain prairies to Asia and to other countries of the western hemisphere, via the Atlantic seaports, will, in a very few years, reach these same destinations via Pacific seaports, and with this changed condition will come vastly increased tonnage and revenues to all the trans-continental lines. The diversion of this very traffic on this idea is now receiving the careful attention and consideration of the executive and managing officials of some of the leading lines between Chicago, St. Paul and other middle-western grain centers and the Pacific slope.
>
> It may be timely just now to suggest that the government construct and operate a first-class double-track railway from Kansas City, Mo., to San Diego, Cal., by air-line route. This will open the shortest line, measured by the map, from Boston, New York and Philadelphia to the Pacific coast, along and near the coal fields of the east and of the west this side of the Rockies, and making the most direct line from our great commercial centers to the Sandwich islands and the Philippines.
>
> This, with other lines now working overland, may prove ample for the wants of commerce to the Pacific coast and the Orient, holding trade and travel within our borders pending the experiment of a canal through the fevered climate of the isthmus.
>
> As trade increases it may develop the importance of a direct and a similar line to Seattle, in Washington state. St. Louis, Mo., is a little south of the direct line between New York and San Diego, but the topographical features of the country indicate that possibly a better route may be found from that point, and the bridge over the Mississippi River at St. Louis may prove an important consideration. A survey, therefore, by direct lines should be made from each on these points.

It is news to us that "vast volumes of wheat and other cereals" were being shipped from the Mississippi Valley to Asia. The Nicaragua Canal people have averred all along that one great object for their canal was to carry California's surplus wheat crop to a market in the East, because there was not enough market for it on the other side of the Pacific. However, if any such heavy traffic as the Commissioner anticipates is to be thrown upon the transcontinental railroads, it will not be necessary for the Government to undertake railway construction on its own account to add to their number. Private enterprise can safely be relied upon to furnish all the railways that the traffic can support; and public opinion will very promptly condemn any attempt to involve the Government in new Pacific railroad subsidies or construction.

◆

The Washington Patent Law Association has recently reported upon the various bills pending in Congress for the amendment of the patent laws; and has secured the opinions of a large number of patent attorneys and officials familiar with the work and needs of the patent office and of the courts which try patent causes. The Association has found that general agreement exists upon three points in connection with proposed patent reforms. These are (1), the necessity of carefully studying out some plan to put into the best shape the mass of material piled up in the United State patent office, so that a thorough search might be made by the examining corps, by attorneys making validity searches and by the public generally in search of information; (2), that there are now too many appeals in contested causes in the patent office; (3), that the present arrangement of circuit courts of appeals as courts of final resort is a failure in the patent system, and that one final court is wanted whose rulings will cover territory co-extensive with the grant.

From the first of these conclusions there can surely be no dissent, and we can go further and say that the only possible method of effecting the desired end is through just such a classification of patents by their subject matter as the Patent Office has put into use. At the last session of Congress an appropriation was made for the purpose of improving and perfecting the present classification, and we may expect that no small amount of good will be effected by this. This classification, however, applies of course only to existing United States patents. It is at least worth considering whether the U. S. classification might not be extended and applied to existing British patents. The cost of doing this would be well repaid by the saving in the labor of the examining force and by the greater certainty which would attach to the final allowance of a patent. Of course the classification might be still further extended to cover existing patents issued by other countries; but the difficulty and expense in making use of these patents on account of the necessity of translation would probably prevent them from being generally used by the corps of examiners. The work would be of great value to all seeking to learn the state of the art in a particular field of invention; but if Congress should go so far as to make existing patents in the English language available for consultation, it would do considerably more than anyone expects.

A MODEL CITY CHARTER; THE REPORT OF A COMMITTEE OF THE NATIONAL MUNICIPAL LEAGUE.

In no one point has popular government, as it is carried on in the United States, been more criticised, than in its conduct of the affairs of cities. It is also true, we believe, that more hard work has been done in the endeavor to improve municipal administration than in any other field of governmental reform. State governments and our national government have gone on with little change in their methods of administration, in many cases, since their original establishment; but our cities have many of them had the most kaleidoscopic changes in the organic laws under which they are ruled, and the search for a city charter which shall make good government most easy and misrule most difficult still goes on.

Up to the present time, however, the progress in city charter amendment has been too often a case of the blind leading the blind. Self-styled reformers have urged this or that change in a city charter, and have failed to foresee that certain evils as well as the expected benefits would attend the change. There has been need for a painstaking investigation by competent experts to determine just what form of administration will most conduce to good government. Such an investigation has now been made, and its results are made public at this week's meeting of the National Municipal League, at Indianapolis.

At previous conferences the good and bad points of American municipal government and charters have been discussed at length by many of our ablest students of municipal reform. At the meeting in Louisville, in May, 1897, the following resolution was adopted:

> Resolved, That the Executive Committee appoint a committee of ten, to report on the feasibility of a municipal program which will embody the essential principles that must underlie successful municipal government and which shall also set forth a working plan or system, consistent with American industrial and political conditions, for putting such principles into practical operation; and such committee, if it finds such municipal program to be feasible, is instructed to report the same, with its reasons therefor, to the League for consideration.

In accordance with this resolution a committee was appointed, but with only seven members, as follows:

Messrs. Horace E. Deming, Albert Shaw and

OF THE
UNIVERSITY OF [illegible]

Prof. Frank J. Goodnow, of New York; Geo. W. Guthrie, of Pittsburg; Chas. Richardson, Prof. Leo. S. Rowe and Clinton Rogers Woodruff, of Philadelphia. Through the courtesy of the last-named gentleman, who is Secretary of the League, we have received an advance copy of the report, supplemented by papers by Messrs. Deming, Goodnow, Shaw and Richardson, and also a paper by Mr. Woodruff, reviewing "The Advance of the Movement for Municipal Reform." The report and papers,with anticipated discussion, will occupy the principal part of the attention of the conference at Indianapolis this week.

Although the report has been the subject of much individual effort, and of many conferences between the different members of the committee during the past 18 months, the committee believes "there is haste in leisure," and recommends that the program, papers and discussion be referred by the conference

> to a committee to be appointed by the executive committee of the league, with instructions to complete the work thus begun and to report, for action, a municipal program at the next meeting of the league.

We have thought it best to place the main features of this program before our readers, a large proportion of whom are in close touch with municipal affairs,, as citizens, officials, or in a business way, while few, if any, of them are not indirectly affected, for weal or woe, by good or bad city government. The committee recognizes, and distinctly states, that it is in the technical, administrative side of municipal affairs that much of the best work has been done, a statement that all thoughtful persons, and many of our readers, especially, will confirm.

The committee found that while many of the features of its program are already included in some municipal charter, constitutional amendments would be necessary in most states before all the features could be adopted. The committee, therefore, submits what may be termed a "blanket" constitutional amendment, from which each state may select what is necessary. This shows both the thoroughness of the work done and the magnitude of that which must of necessity be left to others. Every one who has given the matter attention knows how difficult it is to secure constitutional amendments, especially when the prejudices and perquisites of rural legislators are involved. But it is often well to know in advance the difficulties in the way. Municipal reform is becoming a mighty force, which only needs direction, if it keeps on the increase, to insure a fair measure of success regardless of the obstacles it encounters. As already intimated, much of this program can be put into effect without constitutional amendments, while the most sanguine person does not, or certainly should not, expect a program like this to come into universal use in such a republic of republics as ours, where not only several score of states are concerned, but several thousand municipalities as well. The greatest value of any such program must lie in its exposition of the principles involved. Few cities are likely to immediately abandon their present form of government and begin wholly anew under a new charter. We think, however, that no higher praise could be given the committee than the statement that it has come marvelously near presenting an outline of government capable of universal adoption. The reason for this is that it has confined itself to an outline, instead of falling into the common error of going largely into details. A few broad and deep underlying principles, based on wide experience and observation. are presented in sufficient fulness to warrant their ready comprehension and their observance, when once adopted.

The first one of these foundation principles we shall name is that a city charter should confine itself to matters of State, as distinct from local policy, leaving the latter for the municipalities to work out, each in accordance with its local needs, and in the light of experience. Such a plan makes unnecessary and inexcusable that continual legislative interference which is the bane of city government. It also renders it perfectly feasible for cities with a wide range of population to work under one general municipal incorporation act. The extent to which this plan would simplify and clarify state legislation is amazing, as will be appreciated when one reflects, as the committee suggests, on the vast mass of special municipal acts passed by many of our legislatures each year. With a few exceptions these acts may be divided into three classes: (1) Those prepared by and in the supposed interests of the municipality concerned, vouched for by some member of the legislature and railroaded through with little or no change. As such acts are generally prepared by some one not legally responsible, and are enacted without any feeling of moral responsibility, they are likely to be highly objectionable. (2) Bills prepared by individuals or "rings" to compass some private end, which are passed under the party whip or by "log-rolling." (3) Bills prepared to meet local demands but contorted to aid the ends of party managers or to satisfy rural or local prejudices.

To put a final end to all such legislation would be a great benefit to the communities concerned, and it would enable legislators at our state capitals to give more adequate and statesmanlike consideration to the other measures that come before them.

Realizing that the mere removal of the necessity, real or apparent, for special legislation would not be sufficient, the program prohibits all acts not applicable to all the cities or inhabitants of the state, except such as may be passed by a two-thirds vote of all the members of the legislature, and then either approved by a two-thirds vote of the council of the city affected, or passed by the legislature over the veto of the city council by a two-thirds vote of all its members, "which two-thirds shall include three-fourths of the members of the legislature from districts outside the city or cities to be affected." This provision will go far towards satisfying those who feel that in case of emergencies the legislature should be able to pass special municipal legislation, either to meet peculiar local needs or to furnish a check upon local officials when all other means fail. It will be noted that the municipal corporation act itself can be amended at any time, either directly, or by independent legislation, provided such changes or additions are not contrary to the constitutional amendments and apply to all the cities or inhabitants of the state.

To give still more elasticity to the program, where most needed, it is proposed that cities having a population of 25,000 or more may frame their own charters, subject, of course, to the principles laid down in the constitutional amendments.

It may occur to some that with such broad general powers and such freedom regarding details, the government of different cities would take on still more of that regrettable lack of uniformity which already prevails. But it is more probable that the opposite result would follow, for in the first place we should have a large increase of uniformity by the adoption of the same act of incorporation, and next the program recognizes the existence and provides for the continuation of the exercise of supervisory powers on the part of central or state admisistrative boards, like State Boards of Health. Besides this, city controllers, or heads of the finance departments, officials with great powers, are required under the program to report fully to some state official on the financial operations and conditions of each city, in accordance with forms prepared by the state official.

Before leaving the general subject of state control, by legislative or other means, attention should be called to one point forcibly brought out by the report: Extremes of state legislation in local affairs are often nullified by what may be termed local legislation by municipal officers. That is to say, the legislature goes into the details of local legislation, and even of local administration, but its mandates are left to local officials for execution. They use their discretion in the matter, and to that extent usurp legislative power. If the state wishes to exercise administrative powers, for the sake of uniformity or any other reason conducing to the general welfare, it should do so through central administrative bodies.

This brings us naturally to another important principle laid down in this municipal program, viz.: That the legislative and administrative powers of a municipality should be placed in separate hands to the greatest possible extent. We have not space to go into this matter, nor does it seem necessary. The program aims to effect this separation by vesting all legislative powers in the council and all administrative powers in the mayor, and in administrative departments created by the council, but with their members appointed by the mayor. All but the heads of such departments must be chosen by the mayor from lists of candidates certified to by civil service commissioners, these officials also being appointed by the mayor. Each civil service appointment is to be made by the mayor from the three highest names on the list of available candidates, preference to be given to citizens, if of equal rank or grading, honorably discharged from the army or navy of the United States.

Examinations of unskilled laborers are to relate only to "their capacity for labor and their habits as to industry and sobriety."

Probably some persons will feel that the heads of departments should be recognized at least to the extent of providing that they may express to the mayor their preference for some one of the three available candidates in any case, but in considering this matter it should be remembered (1) that the intention of the program is that the mayor and the heads of all departments shall be in harmony, hence the mayor would naturally consult the heads; and (2) that we must divest our minds of the picture, now so common, of a clean sweep of employees with each change of administration, and think of the whole administrative force as very largely continuous. Promotions in the service are to be made in order of merit and seniority, in accordance with rules established by the Civil Service Commission, and the program has the following to say regarding tenure of office:

> No officer or employee in the administrative service of the city shall be removed, reduced in grade or salary, or transferred because of the religious or political beliefs or opinions of such officer or employee; nor shall any official in the administrative service of the city be removed, reduced, or transferred without first having received a written statement setting forth in detail the reasons therefor; a duplicate copy of such statement shall be filed in the office of the Civil Service Commissioners, and at the option of the official who shall have been removed, reduced or transferred, such statement of reasons, together with the reply thereto made by the officer removed, shall be made a matter of public record in the archives of the city. Subject to the foregoing provisions of this act, all persons in the administrative service of the city shall hold their offices without fixed terms and subject to the pleasure of the mayor.

The last sentence, coupled with other provisions of the program, seems to mean that heads of admistrative departments, as well as subordinates, are to hold office until removed for cause, which cause shall be neither political nor religious. The only difference between the appointment of heads of departments and their subordinates would also seem to be that the mayor can select the heads in entire independence of the civil service commission or examinations of any sort. This plan should give great stability to the whole administrative machinery of a city, resulting in trained public servants of high technical ability, where such are necessary, and a high grade of efficiency on the part of all the employees, since all know they will be retained if faithful and able and are very liable to have to go if not. It would lift a load of anxiety from many an engineer, superintendent of water-works, streets or sewers, for instance, if he knew he were not liable to lose his position at the next election.

The only appointment made by the city council, except those pertaining to its own officers and servants, is the city comptroller, or head of the finance department. But while the council is shorn of all appointments save these, its functions in other respects are very greatly increased, as compared with the general American practice at present. All legislative functions are lodged in it, instead of being deposited, as is now so common, in boards of public works and other bodies having both legislative and administrative powers. Two other additions to the dignity and importance of the individual councillor are (1) that the legislative body is composed of but one branch, and (2) that the term of office is for six years. The acts of the council are subject to the mayor's veto, but this may be overridden by a certain majority (left blank in the program). The mayor, and not the council, prepares the annual budget, and the council cannot increase, but it may decrease, any item. On the other hand, the council makes specific appropriations of available funds, which the mayor may veto in whole or part, but the veto may be overridden. The total indebtedness and the percentage of the tax rate to the total valuation of the city are to be limited in the charter, but the fixing of the limit is left to the discretion of the state legislature. Debts for revenue-producing works are to be excluded in determining whether the city has reached the bonded debt limit, while reports on this and other financial matters are to be made by the city comptroller to a state officer or commission, and are designed to place each city's officers under some surveillance.

The policy of each city as to municipal ownership of water-works, lighting plants, street railways, and all such undertakings, either through purchase or construction, is left to the council, and the exclusion of debts for these purposes from the aggregate used to determine the debt limit gives councils more scope in this matter than they ordinarily have.

When franchises are granted they must be in the nature of leases for 21 years, with a payment to the city of a percentage of the gross revenue, and provisions for ultimate acquisition of the works in question, the price to include nothing for the value of the franchise, and the method of determining the purchase price to be stipulated in the franchise. To the end that the city shall be possessed of full information regarding all franchise-holding companies, such companies must report fully to the city their financial transactions, and these reports shall be public records. To render the omission of such reports less likely, and to ensure the inclusion of the desired figures, the program provides as follows:

> The accounts kept by a city shall, among other things, be designed to show in each case of a grantee of a franchise from the city rendering a service to be paid for wholly or in part by payments by users of such service:
>
> (1) The true and entire cost of construction, of equipment, of maintenance, and of operation thereof;
>
> (2) The amount of the cost collected annually from users of the service, and the character and extent of the service rendered to users in consideration for the payments by them;
>
> (3) The amount of the cost collected annually from taxpayers as such, and the character and extent of the service rendered the city in consideration for the amount paid annually for such service by taxpayers.

We have urged for years that franchises should be limited as to length, and be drawn with more care for the interests of the cities concerned. We have also pointed out, if we remember correctly, the advantages to both companies and cities of having greater publicity in the accounts of franchise companies. These advantages are seen and appreciated by some holders of such franchises and corporation lawyers.

A novel feature of the program, so far as American practice is concerned, is the provision that heads of departments, ex-mayors and mayors, may participate in the deliberations of the council; of course they cannot vote. The councilmen are to serve without pay, and to be elected on a general ticket, instead of by wards or districts.

One feature of the program which is open to objection is the limitation of all contracts for services or material to five years. There are some services which can be rendered much more economically to the city under a contract for a longer term of years, such as garbage disposal, where an expensive cremation or reduction plant must be provided. Under a five-year contract the risk of failure to secure its renewal must be offset by higher prices. The same thing is true to a large extent of electric lighting contracts.

Somewhat in the same category is the provision that all bonds must be redeemed within 20 years. Indebtedness for some purposes might very properly be extended over a longer period, depending, somewhat, upon the life or availability of the thing acquired. Thus, real estate or water rights, which will appreciate, rather than depreciate, in value, and serve future generations, might be paid for in longer term bonds than those issued for a pumping plant. But the time limit on both contracts and bonds is right in principle, and it must be remembered that this is a propaganda of principles rather than of detailed requirements.

Finally, it is to be noted that the program provides for municipal elections separate from state or national elections; for minority, proportional or other form of representation in the city council, to be determined by the vote of the people, either when the question is presented to them by the council, or by a petition signed by a certain percentage of the qualified electors; and that all nominations to elective offices are to be made by petition signed by legally qualified voters. The last provision is designed to vest the nominating power in the people instead of in the managers of the political machines.

LETTERS TO THE EDITOR.

Comparative Economy of "A" Type and Riveted Trusses for Short Spans.

Sir: The article published in your issue of Aug. 25, 1898, "Bridge Work on the Kansas City, Pittsburg & Gulf R. R.," contains a description of the patented "A" truss designed for short spans, and gives stress sheets, details, etc., for 100-ft. single track through spans as actually built in 1893. The advantages claimed for this type are, to quote the article referred to, great rigidity in all directions, ease and cheapness of erection, and economy in metal when structures of this type are compared with structures of other types having equal strength and rigidity. The inventor "considered the ordinary through Pratt truss too light and vibratory, and the riveted truss as then built, clumsy, unscientific and uneconomical." The faults of the short span Pratt truss were so well known in 1893 that it is safe to say that this type had about ceased to be used for 100-ft. spans at that date, but an examination of some of the riveted bridges designed in 1893 or constructed previous to that year will show that the criticisms applied to this type are not well founded.

The span shown in Fig. 1 is one of several built for a leading railway in the latter part of the year 1891. These spans were designed for a live load approximating that used in the design of the "A" type spans described in the article referred to, but were built of iron and were consequently heavier than if they had been built under "steel" specifications. An examination of the drawing does not reveal a want of science or an appearance of clumsiness either in detail or in general design. Fig. 2 shows a span designed in 1893, but not built. The span was designed for practically the same live load as the "A" type span and the sections proportioned for "steel unit stresses." Comparing the trusses and upper bracing of the span with the "A" truss, since the flow and lower lateral system could be made the same for both spans, we find a difference in both weight and stiffness in favor of the riveted type as follows:

	Type "A."	"Rvtd." Type.	Difference.
Weight, trusses and upper bracing, lbs.	66,900	50,700	16,200
Calculated max. live load, deflect'n, ft.	0.0453	0.0377	0.0076

With such a difference in both weight and deflection favorable to the "riveted" type it would seem that this type is by far the best for such crossings and has the additional advantages of presenting a pleasing appearance to the eye, which cannot be said of the "A" type. In the matter of erection the only difference would be in driving about 800 more rivets in the riveted type than the "A" type, a small disadvantage when the additional stiffness obtained by using rigid joints is considered. Should the riveted span be made to weigh the same as the "A" span the additional metal thrown into bracing or into the trusses would increase its rigidity greatly, a point in which it already has the advantage with its lighter weight.

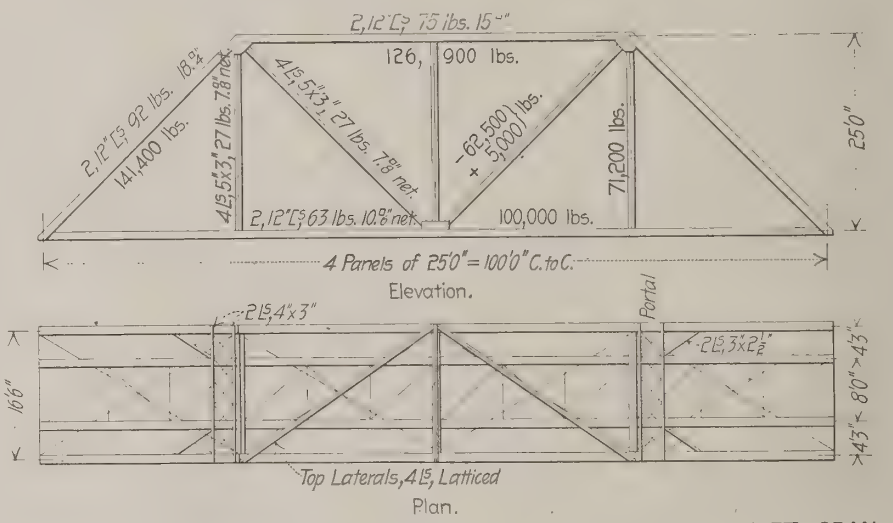

FIG. 1.—WROUGHT-IRON RIVETED TRUSS RAILWAY BRIDGE OF 100-FT. SPAN DESIGNED IN 1891.

Respectfully yours,
H. C. B.

Philadelphia, Pa., Oct. 1, 1898.

(In accordance with our usual practice, we submitted a proof of the above letter to Mr. Waddell, and we append his reply below.—Ed.)

Sir: In answer to H. C. B.'s letter of Oct. 1, I would state that his principal point was well taken, in that the type of bridge he illustrates is good. I have been using it for the past year or two, and have found it very satisfactory. However, it was not in common use in 1893, and can hardly be said to be so to-day. My disparaging remarks concerning the riveted trusses of those days referred to the lattice girder or multiple intersection truss.

H. C. B.'s comparison of weights appears to be faulty, showing as it does that the A truss requires 16,200 lbs. more material than does the riveted truss. As a part of my office records, I have just completed a book of diagrams of weights of fixed spans of all ordinary kinds for all classes of the "Compromise Standard System of Live Loads for Railway Bridges," designed in strict accordance with the specifications of "De Pontibus." Referring to this I find the following weights of metal for 100-ft. spans of Class X, which is the standard adopted by the Kansas City, Pittsburg & Gulf Ry. Co., the owner of the structures under consideration:

A truss span........................	1,240 lbs. per lin. ft.
Riveted truss span	1,190 " " "
Difference in favor of the latter =...	50 lbs. per lin. ft.

or 5,000 lbs. for the span.

This extra weight of metal is more than offset by the more expensive field riveting of the lighter bridge.

I must acknowledge that the result of my assistant's computations in respect to the weight of metal in these two types was a surprise to me, as I had not hitherto recognized such great economy of metal for the riveted type. As for the deflections, theoretical figures don't amount to much, especially on such short spans. H. C. B. finds maximum deflections of 0.54-in. and 0.45-in. for the A-truss and the riveted truss, respectively. The engineer who put up one of my 100-ft. A-truss spans found only 0.31-in. with the heaviest load he could get on the bridge, so it is safe to conclude that the maximum load would not have brought the deflection up to 0.4-in.

One great advantage of the A-truss bridge is the ease, rapidity and economy in its erection, while nothing that I have ever seen can beat it for rigidity. Moreover, its appearance is by no means unpleasing to the eye, as H. C. B. claims it is; at least, this is what everyone tells me who has examined this type of structure, and the accompanying view of one of the A-truss bridges erected on the line of the K. C., P. & G. Ry., as above noted, will also enable each reader to judge for himself to some extent in this respect.

Very respectfully yours,
J. A. L. Waddell.

Gibraltar Building, Kansas City, Mo., Nov. 12, 1898.

An Opportunity for Bridge Engineers to Practice Engineering Ethics.

Sir: We have heard a good deal about the "ethics" of the engineering profession from time to time, but beyond mere academic discussion nothing has been accomplished toward a code of action, and probably nothing ever will be from the nature of men and things, and from the fact that engineering is as much a business as a profession. While abstract preaching on such matters cannot be crystallized into concrete organized action among engineers, it has, however, its value in quickening the conscience, so that the individual may aspire to a greater reverence for the golden rule, and a respect at least for the eighth commandment, "Thou shalt not steal," which last injunction, by the way, was the sole platform on which a great political campaign was recently fought in an adjoining state.

The above remarks are apropos of the circular of the Quebec Bridge Co., issued to the bridge builders of this country. This circular affords the profession as represented by our great contracting firms an opportunity to exhibit the extent of their interest in the ethics of the profession. The Quebec Bridge Co. has in view one of the most difficult technical problems of bridge building ever presented to the profession. With a gall unparalleled, it has issued an invitation to contracting engineers to come to its aid and expend large sums of money to furnish it brains and experience, and binds itself to nothing in return therefor. It is known that this company has yet to be financed, and the magnitude of the enterprise makes it very doubtful whether it is commercially warranted, even with a liberal government subsidy or guarantee, which is hoped for, but not secured. The invitation is accompanied by an elaborate set of specifications covering the requirements which must be met, such as loads, strains, spans, grades, etc. Several variations of design are asked for under different conditions, any one of which is a special computation, involving vast labor. They will graciously receive anything in the suspension bridge or cantilever line, the only two possible directions in which the problem can be met.

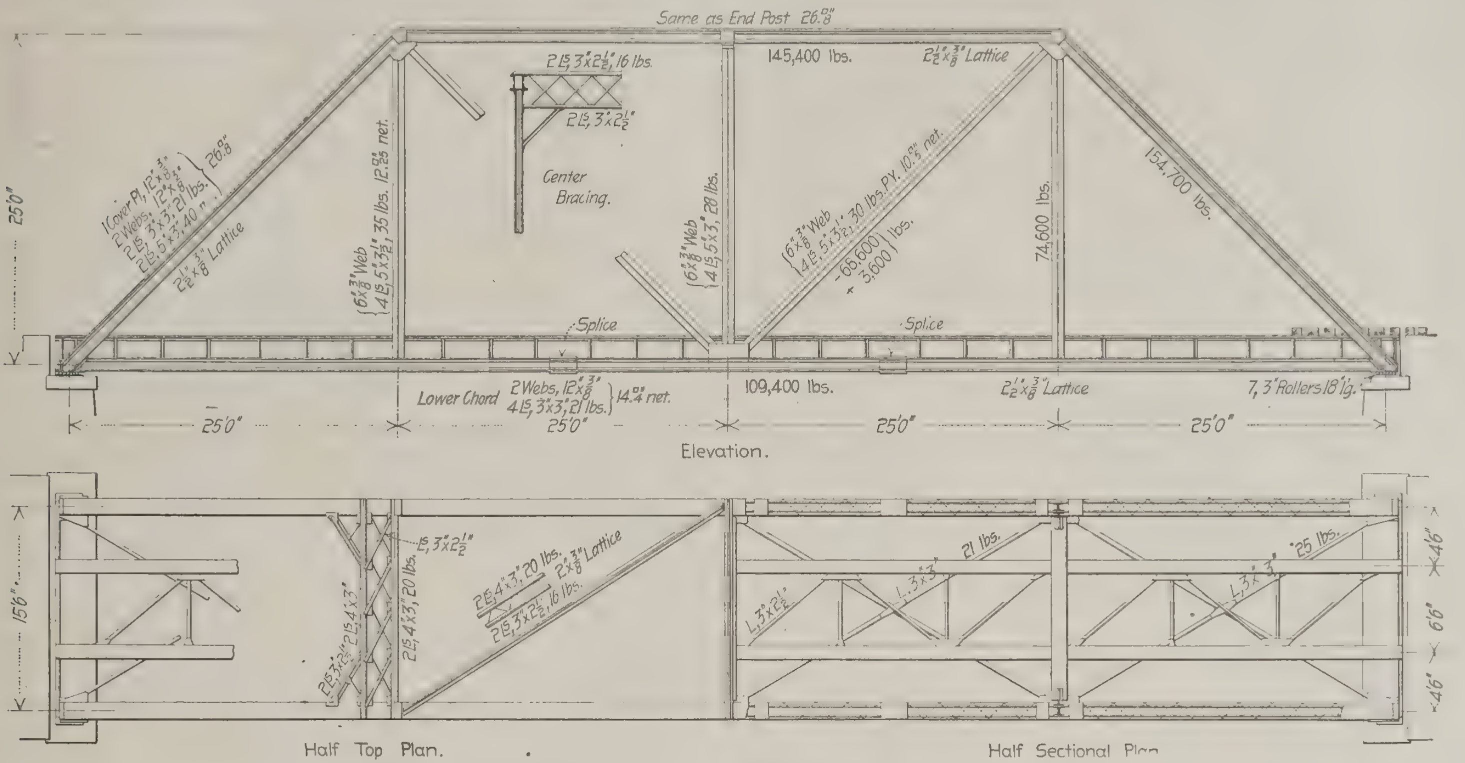

FIG. 2.—STEEL RIVETED TRUSS RAILWAY BRIDGE OF 100-FT. SPAN DESIGNED IN 1893.

This is a deliberate attempt to get something for nothing, and to obtain practical information at a great cost to everybody foolish enough to furnish it, with which the bridge company will endeavor to formulate a plan of financing on which to appeal to capital. If our contracting firms are fools enough to put at the disposal of such a concern as the Quebec Bridge Co., without compensation or a pledge of any kind, their computing room, and their drawing room, for three or four months, with their accumulated experience of years, they will only have spent their money for the pains, and receive a polite thank you (possibly) from the bridge company. It may be urged that the above method is pursued as a matter of common practice and is therefore not dishonest or immoral. In answer it may be said that most corporations furnish their own plans complete on which tenders are invited, and in other cases, when the contractor furnishes his own plans, it is for corporations prepared to proceed with their work, and on the understanding that the competition invited has a conclusion in a definite award. A contracting company will sometimes back an enterprise in promotion, spending large sums in plans and engineering, for a possible reward to accrue to itself alone, but this is its own affair and is dishonest to no one. But a cold-blooded attempt in cunningly appealing to the business instinct of greed and competition, for the purpose of obtaining, free of cost and obligation, the accumulated experience of the country, simply to find out what can be done so as to get something tangible to go before capital on which absolute cost can be predicted, should be met by our American contracting engineers with indignant refusal. If the engineers of the bridge company are unequal to design a structure to meet the problem, the honorable course to have pursued would have been to have offered a prize or prizes for the best plan, or better, to have selected some half dozen concerns or engineers of established reputation, paying them at least the cost of their outlay for preparing their plans, and submit the competition to a board of engineers for selecting the best and most suitable; the selected plan to be adopted and paid for, either by award of the contract to the successful party or on a per centage basis usual for such works.

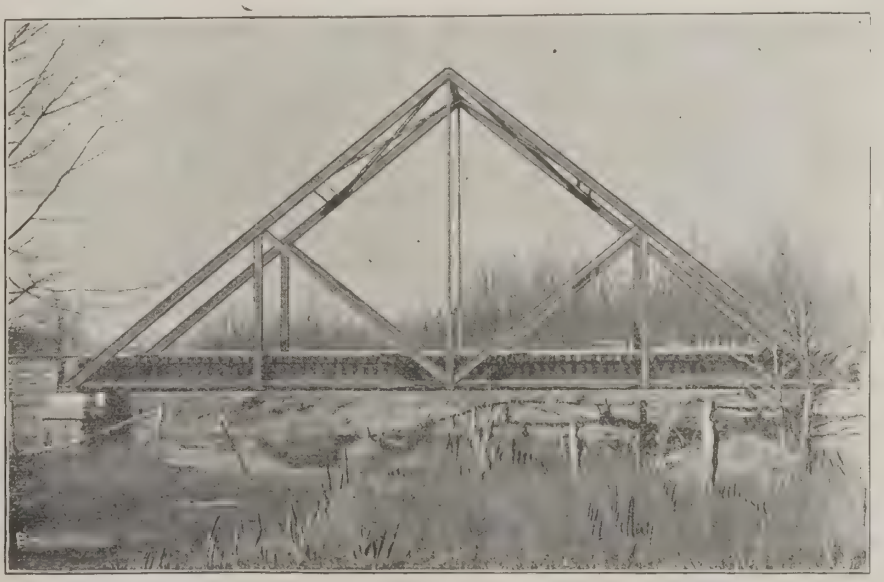
It would seem as if the Quebec Bridge Co. were financially unable to pay for the information they are seeking, specifically avoiding, as they do, all obligation of any kind, and until they are in a position to bind themselves to a conclusion which would afford some protection to competing parties, it is sincerely hoped that our great engineering firms will let the enterprise severely alone, not only in the interest of good professional morals, but also of their own pockets. To be made use of is bad enough, but to be made use of at a cost of some thousands of dollars, without the slightest contingent promise even, is a good deal worse.

A. P. B.

New York, N. Y., Nov. 14, 1898.

◆

(According to our usual practice, we submitted a proof of the above letter to the Quebec Bridge Co., Ltd., with the privilege of replying in the same issue to the criticisms contained in it. We append the reply received from the Secretary of the company.—Ed.)



100-FT. SPAN A-TRUSS BRIDGE ON KANSAS CITY, PITTSBURG & GULF RY., NEAR JOPLIN, MO.

Sir: The action for which the Quebec Bridge Co. is so severely arraigned before the tribunal of public opinion, is the fact of having at once invited tenders and competitive designs for a cantilever or a suspension bridge, without furnishing more than a general plan and general specifications. Your correspondent, A. P. B., condemns such a method as being a transgression of the law of ethics which he suggests should govern the engineering profession, but his own admission that there is not, and probably never will be, a written code to the effect he aims at, should have extenuated in his own judgment the gravity of the offence, if any. Particular cases are very seldom dealt with by the simple use of abstract principles or aphorisms, and with a little reflection, very rash applications of the eighth commandment would sometimes be avoided.

The undersigned hastens to repudiate, in behalf of the Quebec Bridge Co., any such intent or motive as is so freely imputed to the latter by your correspondent. The procedure decided on, to ask at once for competitive designs and tenders, was no "deliberate attempt to get something for nothing," but the natural outcome of circumstances about which A. P. B. manifestly knows nothing. It was adopted purely and simply because it then seemed to be the speediest arrangement for the purpose in view. The prize competition system was not entertained, because it does not generally bring up the same reliable class of respondents as if coupled with a formal invitation to tender for the work. In the first case, a scale of money reward is offered for the two or three first best designs, because designs alone are in view; in the second, the prize, being the letting of the contract to the most deserving, is generally considered well worth the risk. At all events, I beg to affirm that the decision to ask bridge building firms to tender on their own designs was taken in good faith, with no such dishonest aforethought as is imputed by A. P. B., and that it was arrived at only after it had been ascertained that the arrangement would be accepted as perfectly honorable by a sufficient a number of big contracting companies to justify us in calling for tenders in that manner. As to those, if any, who would be inclined to share A. B. P.'s opinions on professional dignity, their course is very easily traced: it is to refrain from tendering, but it is no reason for attacking our bridge company in the way A. P. B. does, any more than for describing as fools those who are willing to compete at once for the designing and the construction of our bridge.

As to the financial aspect of the question, on which your correspondent bases his whole argument, we squarely deny his right and qualifications to discuss it. His imputation that this company, composed as it is of 200 of the best citizens of Quebec, is unable to pay a few thousand dollars for the technical information it requires, and that it attempts to collect that information by crooked ways without any practical intention to use it, plainly shows he does not know what he is talking about. He surely does not contend that a private company ought to take the public in the confidence of its internal arrangements. How then can he speak of this company's inability to finance, and of the special conditions of its understanding with capitalists, as well as with the government and the city of Quebec? I have just now explained that, at the time the tenders were advertised for, it was with the express purpose to save time and to award a contract on the best competitive design thus secured, after due analysis by a board of competent engineers, in order to be ready to start work as early as possible next spring. I fail to see what dishonesty there is in such proceedings. Your correspondent admits himself that "when the contractor furnishes his own plan, it is for corporations prepared to proceed with their work." Such being our case, his whole argument falls to the ground, and he might have spared your readers his eloquent, though unjustified, sermon on professional ethics.

Ulric Barthe,
Secretary Quebec Bridge Co., Ltd.

Quebec, Canada, Nov. 25, 1898.

NOTES ON THE DEFINITIONS OF SOME MECHANICAL UNITS.*

By William Kent, M. Am. Soc. M. E.

The following paper has been suggested by recent discussions in the Society for the Promotion of Engineering Education, in which considerable difference of opinion was shown to exist between the physicists and the engineers in regard to definitions of the commonly used terms: force, mass, weight, etc.

If a body at rest, but free to move, whose mass is M, be acted on by a constant force, F, during a time, T, it will acquire at the end of the time a velocity, V.

The equation of the four quantities, M, F, T and V, is

$$F\ T = M\ V,$$

provided that the magnitude of the units in which these four quantities are measured, in any system of measurement, is such that the unit force is that force which will give the unit mass unit velocity in unit time, so that we may write

$$1\ F = \frac{1\ M \times 1\ V}{1\ T}.$$

From the equation F T = M V, we may obtain the four equations:

$$F = \frac{M\ V}{T}.\quad (1);\quad T = \frac{M\ V}{F}.\quad (2);\quad M = \frac{F\ T}{V}.\quad (3);$$

$$V = \frac{F\ T}{M}.\quad (4);$$

and from these four equations we may obtain definitions of the four unit quantities, each in terms of the other three, as follows:

(1) Unit force is that force which will give unit mass unit velocity in unit time.
(2) Unit time is that time in which unit mass will acquire unit velocity when acted on by unit force.
(3) Unit mass is that mass which will acquire unit velocity when acted on by unit force for unit time.
(4) Unit velocity is that velocity which unit mass will acquire when acted on by unit force for unit time.

These four statements, however, are not really definitions. They are simply expressions of arithmetical equalities. They have their analogues in the definitions based on the electrical formula C = E ÷ R, in which C is current in amperes; E, electro-motive force in volts, and R, resistance in ohms. Thus, unit current is that current which unit electro-motive force will cause to flow through unit resistance. Unit electro-motive force is that force which causes a current of one ampere to flow through one ohm. Unit resistance is that resistance through which one volt will cause to flow a current of one ampere.

These three definitions, as well as the four first given, are examples of reasoning in a circle. The definition of each quantity is expressed in terms of the other quantities. We may have other definitions, however, in which each term is defined independently, without reference to the other terms. Thus, in electricity unit current may be defined as that current which will deposit in a given time a certain amount of silver from a standard solution; unit electro-motive force as the electro-motive force existing between the poles of a certain standard cell; unit resistance as the electrical resistance of a certain piece of metal under certain standard conditions.

So in mechanics, unit mass may be defined as the mass of a certain piece of metal, such as the British pound, or the gramme. Unit force may be defined as that force with which the standard pound is attracted to the earth at London, or as some fraction—say, 1 ÷ 32.2 of that force; or, it might be defined as that force which will stretch a certain spring a certain distance, or, as that force which will elongate a certain steel bar a millionth part of its length. Unit velocity may be defined as the quotient of a certain distance divided by a certain time, the distance being the length of a certain piece of metal. Unit time may be defined as 1-86,400th part of a mean solar day, or, as the time in which a certain pendulum makes one vibration at London.

Referring again to the equation F T = M V, and choosing our units so that the unit force is that force which in unit time gives unit velocity to unit mass, we may obtain the following statements of the relation of the four unit quantities, F, T, M, V:

F × T = M × V

1 poundal acting for 1 second on 1 lb.
gives a velocity of 1 ft. per sec.

1 lb. " " 1 second on 1 massal
gives a velocity of 1 " " "

1 " " " 1 second on 1 lb.
gives a velocity of 1 gravital per sec.

1 " " " 1 timal on 1 lb.
gives a velocity of 1 ft. per sec.

The term "poundal" has been used by some English writers on mechanics. The terms "massal," "gravital," and "timal" have been invented for the purposes of this paper only. It is to be hoped that they will never be used in the text-books, and that the term "poundal" will soon be expunged from those text-books which have adopted it.

One pound force is the force with which gravity acts on the standard pound at London; 1 poundal is 1/32.19 of this force; 1 lb. mass is the mass of the standard pound; 1 massal is 32.19 lbs.; 1 gravital is 32.19 ft.; 1 timal is 1/32.19 of a second.

In the C. G. S. system, we have

1 dyne acting for 1 second on 1 gramme
gives a velocity of 1 cm. per sec.

1 gramme " " 1 second on 981 grammes
gives a velocity of 1 " " "

1 " " " 1 second on 1 gramme
gives a velocity of 981 " " "

1 " " " 1/981 sec. on 1 gramme
gives a velocity of 1 " " "

The "dyne" is a term used in the text-books. It is the force with which a mass of 1/981 gramme is attracted by gravity at Paris. New names might be invented for the quantities 981 grammes and 1/981 sec. 981 centimeters is 1 gravital, or 32.19 ft.

Out of the eight statements given above, we may select those that are most convenient for any given purpose, such as engineering practice, and throw away and forget the others, since the unnecessary multiplication of formulas, terms and definitions only gives rise to mental confusion and error. In engineering, with English weights and measures the third statement is practically the only one that is needed, and, translating the useless term gravital into its equivalent, we may write it: A force of 1 lb. acting on 1 lb. mass for 1 second, gives it a velocity of 32.19 ft. per second.

It may be convenient in electrical or stellar physics to use the dyne, or its multiple, the megadyne, but there seems to be no use in English measurements for the poundal, nor do we need any such terms as the gravital, the massal or the timal.

Prof. John Perry, in his work on "The Calculus for Engineers," London, 1897, says:

> I venture to say that there is not one practical engineer in this country who thinks in poundals, although all the books have used these units for 30 years.

The word pound is used in two senses, as the unit both of force and of mass (or weight). This need introduce no confusion, for whenever it may be necessary to make a distinction, we may say a pound force, a pound mass, or a pound weight.

We may rigidly define the pound force as the force which gravity exerts on the standard pound (a piece of metal) at London. The pound mass, or weight, is the standard pound itself.

It will be noticed that we cannot express the relation F T = M V in terms of the pound (or gramme) unit of mass and force, the second of time and the unit of velocity 1 foot (or 1 centimeter) per second, but in the English system we have either to introduce the numerical coefficient 32.19 or 1/32.19, and in the French system 981 or 1/981; or else, to invent a new unit such as the poundal, dyne, gravital, etc., in order to obtain an equation. If our unit of distance were 32.19 ft. of 9.81 meters, instead of 1 ft. or 1 centimeter, then we could express the equation without such a coefficient or new term, but the benefit would be infinitesimal in comparison with the confusion that would result from the introduction of a new unit of length. There is just as much reason, however, for using a new unit of length, such as a gravital, meaning 32.19 ft., as there is in using a new unit of force, such as the poundal.

The word mass, in what is said above, has been used in the sense in which it is used in the text books on physics, but it is used in another sense by most writers on engineering, namely, as the quotient arising from dividing the weight of a body at London by 32.19, or by dividing its weight (defined as the resultant of the attraction of gravitation upon it), at any other place by the acceleration due to gravity at that place, say 32.16 at latitude 45° at the sea level.

Some confusion often arises in the minds of engineering students from the use of the word mass in these two senses, and a like confusion sometimes results in the two senses in which the word weight is used. The definition of weight, above given—the resultant of the attraction of gravitation—is not the definition used in commerce or in engineering. The common definition of weight is quantity of matter as determined not by bulk (which is one meaning of the word quantity), but by weighing it; that is, comparing it by means of an even balance or platform scale with a standard weight, such as the pound. In common language, we say that we weigh a body; determine how much it weighs; obtain its weight in pounds, and these pounds are standard units of weight, so declared by act of Parliament, and so defined in the dictionaries. Modern writers on physics, however, say that this language is all wrong; that we should use the term mass instead of weight, when we refer to quantity of matter, and not to the attraction of gravitatation upon it. We should therefore say, perhaps, that we mass a body; determine how much it masses; obtain its mass in pounds, and that the act of Parliament was in error when it called the standard pound a weight and not a mass.

The definition of mass, commonly used by engineering writers, and sanctioned by such authors as Weisbach and Rankine, is the quantity of matter as expressed by the term W ÷ g, in which W is the weight of the body at London (either the attraction of gravitation on it at London, or its quantity as determined by comparing it with the standard pound anywhere on earth), and g is the London value of g, or the acceleration due to gravity at London, or 32.19. If, however, the weight of the body is that determined by weighing it on a spring balance standardized at London (which is not done in commerce or in engineering in the United States), then the mass would be the weight so determined, divided by the value of g at the place where the weighing is done.

The engineer uses the word weight in the sense in which the common people use it, and have used it ever since the word was known in the English language, and in the sense in which the physicist uses the word mass. The engineer uses the word mass to mean weight divided by 32.19, usually taken as 32.2.

Formulas commonly used by the engineer are

$F\ S = \frac{1}{2}\ M\ V^2$, formula for energy;
$F\ T = M\ V$, " " momentum;
$F = M\ A$, " " force causing acceleration;
$V = \sqrt{2\ g\ S}$, " " falling bodies, or for height due to velocity.

In the first three of these formulas the engineer always uses the pound as the unit of the force F, and for M he substitutes W, the weight in pounds, divided by 32.2. In the fourth formula, for accurate work, he must use the value of g for the latitude to which the particular problem in hand applies.

The difference between the physicist and the engineer is merely one of definition. There may be no objection to the physicist using for his own purposes the terms and definitions which he finds most useful or convenient, but it is an open question whether the physicist has the right to denounce the engineer's terms and definitions as improper, or whether it is advisable for the text-books used in teaching mechanics to engineering students, to use the definitions of the physicist instead of those of the engineer. The use of the term "poundal" is especially objectionable, for it is not used anywhere outside of the text-books, in any art, industry or profession. Much confusion in the minds of students of mechanics would be avoided if the term were denounced and dropped from the language.

A HOTEL IN SAN FRANCISCO BURNED to the ground on Nov. 24, causing the loss of five lives, the injury of four persons, and the destruction of over $2,000,000 worth of property. It is understood that the fire started in the café kitchen, and at the time there were several hundred guests and employees in the hotel. The building, owned by E. J. Baldwin, was completed in 1877, at a total cost of about $3,000,000, including ground. It was irregular in shape, being 200 × 400 × 300 ft. and 6 stories high, and it contained a theatre and several large stores on the ground floor.

◆

THE LOSS OF THE STEAMER "PORTLAND," of the Boston & Portland Steamship Co., off Highland Light, Mass., occurred in a severe storm on Nov. 27. The entire crew and all passengers, numbering about 117, were lost. The accident is attributed to a breakdown in her machinery, which allowed the vessel to drift onto the shore during the severe storm of Saturday and Sunday. The "Portland" was built in 1890 at Bath, Me., and was a side-wheel steamer 250 ft. long, 42 ft. beam, and 13 ft. deep, with a net tonnage of 1,317.

◆

A SUIT FOR INFRINGEMENT of the Hyatt patent on the use of a coagulant in connection with mechanical filters has been brought against the Jackson Filter Co., of St. Louis, by the New York Filter Mfg. Co. A hearing will be held on Dec. 13, in the U. S. Circuit Court, Eastern District of Missouri.

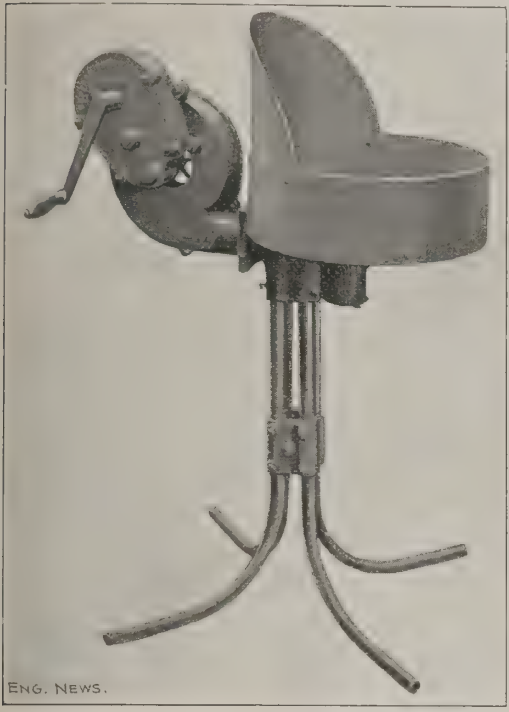
*A paper read before the session of Mechanical Science and Engineering of the American Association for the Advancement of Science, Boston meeting, August, 1898.

A PORTABLE FORGE WITH DETACHABLE PARTS.

The accompanying cut illustrates a new portable forge, manufactured by the Buffalo Forge Co., Buffalo, N. Y., which has some interesting features. For convenient packing and transportation it may readily be taken apart by loosening the clamp on the legs and the set-screws at the base. The crank is rigidly fixed to the shaft, which drives the gears enclosed in the dust-proof case, but the gear-case and the blower are both detachable from the tuyere pipe. No belts or chains are used in the driving gear, which consists of four spur gears, the two larger wheels having respectively 108 and 90 teeth, and the two pinions each 16 teeth, thus increasing the speed 37.96 to 1. The blast wheel is 9 ins. diameter, with five curved blades riveted to a sheet steel flange on each side. With 30 revolutions of the crank shaft per minute the peripheral velocity of the blast wheel is 2,684 ft. per minute.



Portable Forge, with Detachable Parts.

Manufactured by the Buffalo Forge Co., Buffalo, N. Y.

The body of the fire pan is made of No. 14 sheet steel. The total weight of the forge set up for use is 125 lbs. When taken apart and packed for easy carrying, it may readily be carried about scaffolding by one man. The gears are machine cut, the fan wheel is balanced, and the bearings are well finished, all contributing to ease of operation.

THE BURSTING OF SMALL CAST-IRON FLY-WHEELS.*

By Chas. H. Benjamin, M. Am. Soc. C. E.†

Of late years the failure of large fly-wheels have become alarmingly common. Every month brings its record of one or more disasters of this sort, some of them entailing loss of life and serious destruction of property. It is not the purpose of this paper to discuss the causes of such accidents, further than to notice the fact that the high belt speeds and close regulation required in electric plants have been indirectly responsible. Many of the fly-wheels have failed on account of excessive speed due to disarrangement of the governor and consequent racing of the engine. In some instances it has been difficult to determine the cause on account of the destruction and excitement at the moment. In no small number of instances, however, the wheels have burst at speeds but slightly above the normal and when the factor of safety was apparently ample.

Mr. James Stanwood, of this Society, was the first to point out the condition of stress existing in a fly-wheel rim and to show that the bending due to centrifugal force might reduce very materially the bursting speed (Trans. A. S. M. E., Vol. XIV., p. 251). This subject was further developed by Professor Lanza, and the probable amount of stress due to bending was indicated as well as its effect upon rim joints (Trans. A. S. M. E., Vol. XVI., p. 208). It occurred to the writer that a series of experiments on small cast-iron wheels might throw some light on the causes of failure and lead to more rational formulas for design.

The quality of the metal in a small wheel is better than in a large, and the stresses due to uneven cooling are much less. The linear speed of rim at which a large wheel will burst will therefore be less than that obtained by experiments on small wheels.

The experiments about to be described were conducted under the immediate direction of the writer at the laboratories of Case School of Applied Science. The wheels were all of cast iron and were clean, perfect castings. Two diameters were used, 15 and 24 ins., and each wheel was a scale model of some actual fly-wheel designed by a reputable firm. The wheels numbered 1 to 10 had solid rims, with the exception of No. 5. Wheel No. 11 was a special wheel, as will be explained later. The wheels numbered 12 to 17 had each two joints in the rim and were 24 ins. in diameter. All the wheels numbered from 1 to 10 were reduced models of a solid-rim fly-wheel 10 ft. in diameter now in use on a 12 × 30 Allis-Corliss engine in the laboratory. The wheels numbered 12 to 15 were models of the same wheel on a larger scale, with rim joints designed by the writer. The two wheels numbered 16 and 17 were models of the fly-wheel of a Corliss blowing engine. Tables I. and III. give the dimensions of the wheels in detail.

To give to the wheels the speed necessary for destruction, use was made of a Dow steam turbine capable of being run at any speed up to 10,000 revolutions per minute. The turbine shaft was connected to the shaft carrying the fly-wheels by a brass sleeve coupling, loosely pinned to the shafts at each end in such a way as to form a universal joint, and so proportioned as to break or slip without injuring the turbine in case of sudden stoppage of the fly-wheel shaft.

One experiment with a shield made of 2-in. plank convinced us that safety did not lie in that direction, and in succeeding experiments with the 15-in. wheels a bomb-proof constructed of 6 × 12-in. white oak was used. The first experiment with a 24-in. wheel showed even this to be a flimsy contrivance. In all subsequent experiments a shield made of 12 × 12-in. oak was used. Even this shield was split repeatedly and had to be re-enforced by bolts. The wheels were usually demolished by the explosion. No crashing or rending noise was heard, only one quick, sharp report, like a musket shot.

The determination of the speed offered some difficulties at first, it being too great for the successful use of a counter or tachometer. A commutator of one break was arranged on the fly-wheel shaft and this connected through the battery circuit with an earphone in an adjoining room. This arrangement worked satisfactorily, giving a clear, musical tone, and the number of vibrations corresponded closely to the speed as measured by a reducing counter shaft and speed counter. It was soon discovered that the audible tone produced by the machine itself when running at a high speed corresponded exactly to the tone in the ear-phone, and consequently the ear-phone was discarded. Two observers, having trained musical ears and provided with tuning forks, had no difficulty in determining the pitch within half a tone, the quarter tones being estimated. The error due to this method did not exceed 5%. The bursting speed of the wheels having rim joints was too low to produce a musical tone with any distinctness, and it became necessary to resort to the tachometer, a counter shaft reducing the speed from two to three times being employed.

Fifteen-Inch Wheels.

Test pieces cast from the same ladle as these wheels were broken in the testing machine, and the following average values obtained for the breaking strength: Tension, 19,000 lbs. per sq. in. Cross-breaking, 39,000 lbs. per sq. in. These wheels were all turned on the face and edges of the rim, and were carefully balanced by winding copper wire around the arms near the rim.

The shape of fracture at the outer ends of the arms in all the wheels usually indicated that the rim broke first midway between the arms, and that then the two parts of the rim flew outward and broke off at the arm.

Wheel No. 5 had two joints in the rim at opposite extremities of a diameter. The strength of the joints was designed to be one-third the tensile strength of the solid rim, but the wheel burst at only 2,925 revolutions per minute with a centrifugal tension of less than one-fourth that of the solid wheels.

Nos. 6, 7 and 8 had only three arms, every other arm having been removed from the pattern before casting. The object of this was to show more clearly the bending of rim due to centrifugal force.

Wheels Nos. 9 and 10 were of the original six-armed type, but with rims turned down to exceeding thinness. The results are summarized in Table I. An examination of the column containing the value of v in feet per second will show that as the segments of the rim between the arms become weaker as beams, either through increase of length or decrease of thickness, there is a falling off in the bursting speed.

TABLE I.—Particulars of 15-in. Wheels Tested.

No.	Area rim, sq. ins.	Weight of wheel, lbs.	Bursting speed: Revolutions per min.	Bursting speed: Feet pr sec. = v.	Centrif'g'l tension = $\frac{v^2}{10}$.	Remarks.
1.	1.4	20.87	6,525	430	18,500	
2.	1.3	20.44	6,525	430	18,500	
3.	1.23	19.12	6,035	395	15,600	Thin rim.
4.	1.04	16.62	5,872	380	14,400	Thin rim.
5.	....	20.87	2,925	192	3,700	Joint.
6.	1.38	19.25	5,600*	368	13,600	Three arms.
7.	1.23	16.56	6,198	406	16,500	Three arms.
8.	.95	13.68	5,709	368	13,600	Three arms.
9.	.75	12.68	5,709	365	13,300	Thin rim.
10.	.65	13.00	5,709	361	13,000	Thin rim.

*Doubtful.

Note.—The diameter of the wheels ranged from 14½ to 15⅛ ins. The breadth of rim was 2 ins., except Nos. 9 and 10, 1⅞ ins. The area of the arms was 0.46-sq. in. Nos. 6, 7 and 8 had three arms, the others six arms.

To determine to what extent the strength is affected by bending, values of $\frac{v^2}{10}$ have been calculated. As has been shown by Mr. Stanwood in the paper before referred to, this expression represents approximately the tensile stress on the square inch of section of rim due to the centrifugal force, for cast iron. By comparing these values with the tensile strength of the iron, viz., 19,000 lbs. per sq. in., the amount of stress due to bending may be estimated. This difference varies from 500 lbs. per sq. in. in Nos. 1 and 2 to nearly 6,000 lbs. per sq. in. in Nos. 9 and 10—being greatest in the wheels with thin rims or few arms. None of these wheels, however, except No. 5, would have been unsafe at the usual limit for fly-wheel rims of 100 ft. per second. Wheel No. 10 would have had a factor of safety of over 12 at that speed.

Twenty-four-Inch Wheels.

No. 11 was a special wheel which had been in actual use. This wheel burst at 3,670 revolutions per minute, or a peripheral speed of 385 ft. per second, which corresponds well with the average speed of the 15-in. wheels. The explosion was very violent, and completely wrecked the shield. The quality of the iron was unknown, save that it appeared clean and close-grained.

Flanged Joints.

The wheels numbered 12 to 15 were of the same model as the 15-in. wheels on a larger scale, but each wheel had two internal flange joints in the rim, midway between the arms. The joints were all carefully planed and the holes drilled to match. The wheels were not turned on the face, but were balanced the same as the others.

The bolts used were of steel, and samples of each broken in the testing machine gave the results shown in the table.

Wheel No. 12 burst at a speed of less than 1,800 revolutions per minute, but the exact speed was not recorded. The flanges broke, but the bolts were uninjured, except for a slight stretching.

No. 13 was a duplicate of No. 12 in every way. The bolts were uninjured but the flanges broken through the bolt holes. The flanges of the pattern were then strengthened by adding ¼-in. to the thickness, the bolts remaining the same.

In wheel No. 14 the bolts failed.

In No. 15, bolts ⅜-in. in diameter were used. The flanges of one joint were badly broken, the bolts remaining whole. The second joint was uninjured.

The results are summarized in Table II. It will be noticed that the rim speed is about one-half that of a solid wheel, and therefore the centrifugal tension about one-fourth. The joints in all the wheels were carefully made, and were relatively stronger than many joints in fly-wheels which are running to-day in our mills and shops. The centrifugal tension at the joint would be greater than that given in Table II., on account of the weight of finages and bolts. At a rim speed of 100 ft. per second these wheels would have a factor of safety of about 3 6-10, which is altogether too small.

TABLE II.—Particulars of 24-in. Wheels Tested.

No.	Shape and size of rim. Bre'dth, ins.	Shape and size of rim. Depth, ins.	Shape and size of rim. Area, sq. ins.	Weight of wheel, lbs.	Flanges. Effective breadth, ins.	Flanges. Efctive area, ins.
11.	2⅛	1.5	3.18	75.25	....	....
12.	4¹/₁₆	.75	3.85	93.0	2.8	1.92
13.	4	.75	3.85	91.75	2.75	1.89
14.	4	.75	3.85	95.0	2.75	2.58
15.	4¹/₁₆	.75	3.85	94.75	2.5	2.34
16.	1.2	2.1	2.45	65.1	...	....
17.	1.2	2.1	2.45	65.0	...	....

Notes.—No. 11 was a solid rim wheel. Nos. 12 to 15 had internal flanges bolted. Nos. 16 and 17 had linked joints—No. 16 with three links, and No. 17 with two. The flanges of Nos. 12 and 13 were 11-16-in. thick; Nos. 14 and 15, 15-16-in. Each joint was bolted with four bolts, 15-16-in. diameter, except No. 15, which had ⅜-in. bolts.

By testing machine:

Tensile strength of cast iron = 19,600 lbs. per sq. in.
Transverse strength of cast iron = 46,600 lbs. per sq. in.
Tensile strength of 5-16 bolts = 4,000 lbs. each.
Tensile strength of ⅜ bolts = 5,000 lbs. each.

Linked Joints.

Wheels numbered 16 and 17 were of the familiar rolling-mill type, with the joints connected by steel links over cast-iron lugs, the links being heated and shrunk on. The dimensions of the lugs and links are given in Table III.

Wheel No. 16 had three links to each joint, one on each face and one inside. Each joint broke on one side, through the rim, without shearing the lugs or breaking the links.

In No. 17 the link was omitted from the inner lug, leaving but two links to each joint. On one side the rim broke as in No. 16; on the other side the lugs failed by breaking off. It is impossible to say which joint failed first. No. 16, with three links, broke at a speed 66% in excess, and No. 17, with two links, at a speed over 50% in excess of that of the wheels with flanged joints.

The strength of the rim at the weakest section is apparently in excess of the strength of the links, whereas it was the rim that failed in each case. It must, however, be remembered that the links were under direct tension, while the rim was subjected to bending in addition.

At 100 ft. per second the factors of safety for Nos. 16 and 17 would be 10¼ and 8 4-10 respectively.

Conclusions.

1. Fly-wheels with solid rims, of the proportions usual among engine builders and having the usual number of arms, have a sufficient factor of safety at a rim speed of 100 ft. per second if the iron is of good quality and there are no serious cooling strains.

In such wheels the bending due to centrifugal force is slight, and may safely be disregarded.

2. Rim joints midway between the arms are a serious defect and reduce the factor of safety very materially. Such joints are as serious mistakes in design as would be a joint in the middle of a girder under a heavy load.

3. Joints made in the ordinary manner, with internal flanges and bolts, are probably the worst that could be devised for this purpose. Under the most favorable circumstances they have only about one-fourth the strength of the solid rim and are particularly weak against bending.

In several joints of this character, on large fly-wheels, calculation has shown a strength less than one-fifth that of the rim.

4. The type of joint exemplified in Nos. 16 and 17 is probably the best that could be devised for narrow-rimmed wheels not intended to carry belts, and possesses when properly designed a strength about two-thirds that of the solid rim.

It is gratifying to notice the fact that since the subject of joints in fly-wheel rims has been so thoroughly ventilated during the discussions before this Society, several of our prominent engine builders have changed the designs of their wheels by bringing the rim joints opposite the ends of the arms.

TABLE IV.—Failure of Linked Joints.

		No. 16	No. 17
Lugs.	Breadth, ins.	0.45	0.44
	Length, ins.	1.0	.98
	Area, sq. ins.	.45	.43
Links	Effect. breadth, ins.	.57	.54
	Thickness, ins.	.327	.380
	Effective area, sq. ins.	.186	.205
Maximum rim area, sq. ins.		2.45	2.45
Net rim area, sq. ins.		1.98	1.98
Strength of links, lbs.		30,540	20,360
Strength of rim, lbs.		38,800	38,800
Bursting speed, revs. per min.		3,060	2,750
Bursting speed, ft. per sec = v.		320	290
Centrifugal tension.	Per sq. in. $= \frac{v^2}{10}$	10,240	8,410
	Total	25,100	20,600
Remarks		Rim broke.	Lugs and rim broke.

By Testing Machine: Tensile strength of cast iron = 19,600; transverse strength of cast iron = 40,400; average tensile strength of each link = 10,180.

The experiments which have just been described, although at times a trifle too exciting, were interesting from first to last. The writer hopes to supplement them by others on models of the more recent rim-joints, and would be glad to receive any suggestions.

The more this subject is agitated, the less shall we have occasion to mourn the destruction of life and property on account of faults in the design of this most necessary element of the steam engine.

A NOTE ON THE STRENGTH OF WHEEL RIMS.[*]

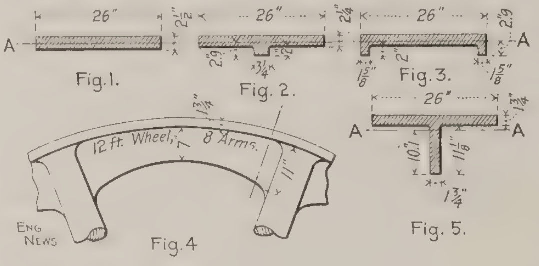
By Albert K. Mansfield, M. Am. Soc. C. E.[†]

On p. 5 of Mr. Supplee's translation of Releaux's "Constructeur" occur these words: "It is upon this point that the peculiar strengthening effect of ribs depends, and which makes their use so advantageous in cast-iron construction."

Then illustrations follow to support the fact that ribbed construction increases strength, that is, is economical of material; but it is not shown there, nor elsewhere to the present writer's knowledge, that this is not universally the case, but that the exact contrary may be the fact.

This may best be pointed out by a practical illustration: The moment of resistance[*] of the rectangular section of Fig. 1 is $\frac{bh^2}{6}$ or $\frac{26 \times 2\frac{1}{2}^2}{6} = 27.07$, AA being the neutral axis.

Now let ¼-in. of the thickness of this section be formed into a rib 3¼ ins. thick, as shown by Fig. 2. Preserving the same total area as before, this rib becomes 2 ins. deep, making the total depth of the section 4½ ins. The neutral axis will be found to be located as shown in the figure, and from a well-known formula the moment of resistance is found to be 18.64; that is, the least moment of resistance, or the moment of inertia divided by the greatest distance of fiber from the neutral axis.



Fly-Wheel Rims of Various Section.

The section has therefore been weakened by the ribs; in fact, unless it represents the special case of a cast-iron beam loaded so that the extreme fiber is subjected to compression, it is only about two-thirds as strong as before. It is seen, therefore, that under some conditions ribbing does not have a strengthening effect. It would clearly be useful to generalize this matter in such a way as to make it easy for the designer to determine when and to what extent ribbing may or may not be resorted to with advantage, but that is beyond the purpose of the present writing.

If we separate the rib of Fig. 2 into two ribs and place them at the ends of the section as in Fig. 3, we have, without change of strength, a section similar to that often used in the construction of wheel rims. The bending moment of such rims, due to centrifugal force, acts with maximum effect near the wheel arms, in such way as to cause tension at the extreme fiber. It will be clear, therefore, that such ribs in such place may make the wheel weaker than it would be if they were not employed. It is not meant that wheels cannot be ribbed in this manner to their advantage, but rather that it is necessary to take care that they are not thus ribbed to their disadvantage. There are many wheels in service which have been strengthened in this negative way.

The destructive accidents which have occurred to large wheels have led to bringing cast iron into disrepute as a material from which to construct such wheels. This fact, coupled with that pointed out above relative to rim-flanges, has led the present writer to the use of the method of ribbing wheels illustrated in Fig. 4, which seems to fill all requirements, enabling cast-iron rims to be made as strong as may be practically desired.

Maintaining the same face of wheel and total area of section as before, let us employ ¾-in. of the thickness of rim in forming a rib 1¾ ins. thick at center of rim; the section then becomes as shown by Fig. 5. The neutral axis of this section is at line AA, and the moment of resistance becomes 77.5, which is nearly three times as strong as the section of Fig. 1, and more than four times as strong as the flanged section of Fig. 3. Of course, a further increase of strength may be obtained by adding to depth of flange.

Now the section of Fig. 5 is taken to represent that next the arms, in which (the case being that of a built-in beam uniformly loaded) the extreme fiber is under tension. The mid-section between arms, however, while acted upon by an equal moment (when the cross-section is uniform), is bent in an opposite direction; therefore the extreme fiber is compressed, which, for equal strength, enables the flange at this point to be reduced, because cast iron is twice as able to resist compression as extension. The modulus of resistance at this point may therefore be one-half as great as at the arms, which will be found to correspond with a flange depth of about five-eighths of that at arms, or in this case about 7 ins.

The proportions are shown in Fig. 4. Almost any desired strength may be attained by this method. It has several other advantages over uniform flanges at edges which will readily occur to designers or wheels.

---

[*] A paper presented at the New York meeting of the American Society of Mechanical Engineers.

[*] [This is more correctly the "section modulus." The moment of resistance is the section modulus multiplied by the resistance per square inch at the extreme fiber.—Ed. Eng. News.]

[†] Mechanical Manager, Buckeye Engine Co., Salem, O.

FORM FOR REPORTING THE RESULTS OF BOILER TESTS.

The Committee of the American Society of Mechanical Engineers, appointed in 1895 to revise the standard code of 1885 for trials of steam boilers, has presented in pamphlet form its report at the meeting held in this city this week. A year ago it presented what was called a "Preliminary Draft of Report," prepared by a sub-committee of four out of the nine members of the committee, requesting full discussion and criticism. In our issue of Dec. 9, 1897, we printed from this "preliminary draft" those sections which differed materially from the code of 1885. In the final report now presented, which, however, is still "subject to revision" before being printed in the volume of Transactions, the amendments to the 1885 code which were in the "preliminary draft" are retained, with a few corrections of more or less importance. The principal new feature of the report in its present shape is the insertion of a "Short Form of Report" of the results of a boiler test, containing only 31 items, as an alternative to the longer form presented last year, which contains 74 items. The short form is recommended for commercial tests and as a convenient form of abridging the longer form for publication when saving of space is desirable. We reprint this "Short Form" below:

Data and Results of Evaporative Test,

Arranged in accordance with the Short Form advised by the Boiler Test Committee of the American Society of Mechanical Engineers.

Made by................on...........boiler, at..........
to determine ....

Grate surface	sq. ft.
Water-heating surface	"
Superheating surface	"
Kind of fuel	
Kind of furnace	

Total Quantities.

1. Date of trial	
2. Duration of trial.	hours.
3. Weight of coal as fired	lbs.
4. Percentage of moisture in coal.........	per cent.
5. Total weight of dry coal consumed.....	lbs.
6. Total ash and refuse	"
7. Percentage of ash and refuse in dry coal	per cent.
8. Total weight of water fed to the boiler.	lbs.
9. Water actually evaporated, corrected for moisture or superheat in steam.......	lbs.

Hourly Quantities.

10. Dry coal consumed per hour.	lbs.
11. Dry coal per hour per square foot of grate surface	"
12. Water fed per hour..................	"
13. Equivalent water evaporated per hour from and at 212° corrected for quality of steam	"
14. Equivalent water evaporated per square foot of water-heating surface per hour	"

Average Pressures, Temperatures, Etc.

15. Average boiler pressure	lbs. per sq.in.
16. Average temperature of feed water.....	deg.
17. Average temperature of escaping gases..	"
18. Average force of draft between damper and boiler............	ins. of water.
19. Percentage of moisture in steam, or number of degrees of superheating...	

Horse-power.

20. Horse-power developed (Item 13 ÷ 34½)	HP.
21. Builders' rated horse-power............	"
22. Percentage of builders' rated horse-power	per cent.

Economic Results.

23. Water apparently evaporated per pound of coal under actual conditions. (Item 8 ÷ Item 3).........................	lbs.
24. Equivalent water actually evaporated from and at 212° per pound of coal as fired. (Item 9 ÷ Item 3)..........	"
25. Equivalent evaporation from and at 212° per pound of dry coal. (Item 9 ÷ Item 5)	"
26. Equivalent evaporation from and at 212° per pound of combustible. [Item 9 ÷ (Item 5 — Item 6)].................. (If Items 23, 24 and 25 are not corrected for quality of steam, the fact should be stated.)	"

Efficiency.

27. Heating value of the coal per pound...	B.T.U.
28. Efficiency of boiler (based on combustible)	per cent.
29. Efficiency of boiler, including grate (based on coal)	per cent.

Cost of Evaporation.

30. Cost of coal per ton of 2,240 lbs. delivered in boiler-room	$
31. Cost of coal required for evaporation of 1,000 lbs. of water from and at 212°..	$

MEDICAL OUTFIT AND INSTRUCTIONS FOR AN ENGINEER IN THE TROPICS.

In the "Medical Fortnightly" of Nov. 15, we find an interesting letter by Albert L. Ashmead, M.D., of New York city, describing a medical outfit which he prepared for his brother, Mr. Percy H. Ashmead, C. E., who has recently sailed to Ecuador to fulfil an engagement as topographical engineer on the line of the Guayaquil & Quito R. R As many of our readers are likely to see servic in tropical countries during the next few years, we reprint in full Dr. Ashmead's description of this outfit, which, it is of especial interest to note, can all be carried in a box only 9 × 12 × 6 ins. in size:

Two porte caustics; to stop a bleeding point; to stimulate a sore that heals too slowly, etc.

Iodoform gauze 10 per cent; as a dressing for wounds, cut off as much as may be required.

Sun cholera mixture tablets; for diarrhea, one every two hours until the diarrhea is checked.

Triplex pills (blue mass, aloes and podophyllin); for torpidity of the liver in the tropics; when there is constipation take one of the pills at bedtime.

Permanganate of potash pills (2-grain); in case of snake bite, take one, and follow at once with a tumbler of water. Repeat every hour. In gonorrhea, dissolve one in a tumbler of water, and use as an injection. As a surgical wash in the same dilution, apply on cotton to the part affected.

Chronic acid solution (1 to 100 parts of water). This is the Orfila prize remedy for viper bites. Use as a wash with absorbent cotton, to the snake bite wound, at once after the biting.

Solution of chloride of gold (1 in 60 parts of water). This is Calmette's remedy for snake bites. On being bitten, after washing the wound with the above acid solution, inject 10 minims (or drops) with the hypodermic syringe, in the sound skin, near the wound; repeat the injection after one hour.

Solution of chloride of lime (Merck's pure 1 in 60 parts of water). This is another of Calmette's remedies. In snake bites, after washing the wound with the chromic acid solution, and injecting in the neighborhood of the wound, the chloride of gold solution (10 minims), inject with the hypodermic syringe, 10 minims of this solution, beneath the sound skin, near the wound. Repeat after an hour's interval.

These three local remedies, the chromic acid wash, the hypodermic chloride of gold, the hypodermic chloride of lime, must be fortified in case of snake bite, by the internal administration through the mouth, of a permanganate of potash tablet (followed by a glass of water) every hour.

Callodion with 2½% salicylic acid. In insect stings paint over the skin, and also in certain skin eruptions, with a piece of cotton wrapt around the end of a stick.

Callodion with 10% idioform; use as a dressing for wounds, painted on the wound, with cotton on the end of a stick, or with camel's hair pencil.

Calomel and soda tablets (each one grain); to stimulate liver, correct disordered stomach, relieve colic, correct torpidity of liver when stools are clay or gray colored, to cause a flow of bile, and when diarrhea refuses to yield to sun cholera mixture treatment, take three of these tablets at a dose. If diarrhea is present, continue taking sun cholera mixture tablets, one at a dose, as before ordered in diarrhea.

Mercury with chalk (12 sample powders, 5 grains each, and one-half ounce in bulk in bottle). In tropical dysentery, with bloody mucus, with straining at stool, with abdominal pain, before bloody mucus stooling, take a five-grain powder, with a five-grain Dover's tablet, every two hours. Continue until the character of the stools change; that is, becomes natural, either brown or green. Watch the gums, if taken more than a day, so as not to salivate. Should blood and mucus appear again in the stools, after having been once checked, or should the straining and the pain return, go through the same course of treatment again. It may be noted here that no case of tropical dysentery can be cured without this course of mercury.

Muriate of pilocarpine, 1-20th grain tablets. One tablet is to be taken by the mouth, and then again after four hours, unless the prostration and the sweating should be excessive. In case of pleurisy, in pernicious congestive malarial fevers, a tablet of pilocarpine.

Dover's tablets, 5 grains each. In dysentery, a tablet with a mercury and chalk 5-grain powder, to be taken every two or three hours. In coughs or colds of every kind, give a tablet every two or three hours (without mercury and chalk), or on going to bed, two tablets at a dose. For fever, malarial or any other, give a tablet every three hours, with a quinine pill.

Quinia Sulph. tablets, 5 grains each. While in the tropics take one every night, even when you are well. In case of chills and fever, take two at night, and one every three hours. In case of congestive malarial fever, or a fever which does not yield at once to this treatment, give two pills every four hours (supplemented by the hot pack, the patient to be wrapped in a sheet wrung out of hot water), until 100 grains of quinine have been taken. While administering quinine, add morning and night five tablets of calomel and soda. If the fever does not yield in two or three days of this treatment, give one calomel and soda tablet every two hours until the mouth is sore from the mercury, and at night time, a purge of one triplex pill. If the purging appears too severe, check it with a sun cholera mixture tablet after each purging.

Carbolized vaseline (1 in 8) for dressing wounds, and for piles.

Surgical needles (half round, 6, assorted) and thread.

Styptic cotton (one bottle) for nose bleed of the Andes, etc. Ointment oleate of bismuth, as a mild dressing for inflamed skin or burns.

One hypodermic syringe, with instruction how to use it.

One can of mustard leaves, for counter-irritation.

Three two-inch roller gauze bandages.

Three three-inch roller gauze bandages.

One pair dressing scissors.

All to be packed in a wooden box with absorbent cotton (one-half pound) 9×12×6 inches. A copy of Dr. Paul Gibier's pamphlet (Bulletin Pasteur Institute, January, February, March, 1897), serum-therapy in snake poisoning, etc., was added to the package.

THE NEW YORK MEETING OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

The annual meeting of the Society, which is being held this week at its house in New York city promises to be as largely attended as was the meeting a year ago, which was the largest in the history of the Society. The meeting was informally opened on Tuesday afternoon, Nov. 29, by the gathering of many members in the spacious parlor, which was for the time being a smoking room, and was formally opened at 9 p. m. in the auditorium, when the retiring president, Mr. Charles Wallace Hunt, delivered his annual address, a portion of which will be found elsewhere in this issue.

On Wednesday morning a business session was held, at which were presented the annual reports of the council, tellers and committees. The tellers reported the election of 22 new members, including 2 promoted from the associate grade, 4 associates, and 13 junior members.

The new officers elected were announced as follows: President, George W. Melville, Chief Engineer, U. S. N., Washington, D. C.; Vive-Presidents, E. D. Meier, St. Louis, Mo., George R. Stetson, New Bedford, Mass., and B. H. Warren, Pittsburg, Pa.; Treasurer, Wm. H. Wiley, New York; Managers, E. C. Felton, Steelton, Pa., R. H. Soule, Philadelphia, Pa., and A. M. Goodale, Boston, Mass.

The Annual Report of the Council contains many matters of interest. Among them are the appointment of a new committee to consider the subject of Standard Pipe Unions, to confer with similar committees of the Railway Master Mechanics and Car Builders' Associations; and the appointment of a committee to report on Standardization or Unification of the Methods of Testing Steam Engines. A letter has been received from the British Institution of Civil Engineers, expressing its desire to welcome the members of the Society in England in 1900 on the occasion of their visit to the Paris Exposition. The membership of the Society now consists of: honorary members, 14; members, 1,395; associates, 123; junior members, 349; total, 1,881. The financial report shows receipts during the year, $32,406; disbursements, $31,755; cash balance, $698; uncollected accounts, $4,486; unpaid bills, $485. Assets over liabilities, $51,285, of which $23,600 is invested in 5% bonds on the building of the Mechanical Engineers' Library Association, and $24,107 is in the volumes of printed proceedings of the Society. The outstanding indebtedness of last year, $3,200, has been wiped out. The Library Association reports net assets of $1,194 in cash and $10,700 in books and manuscripts.

The report of the committee on a standard code for steam boiler trials was presented in pamphlet form. We give an extract from the new code in another column.

After the business session, professional papers were presented for discussion as follows: "Note on Strength of Wheel Rims," by A. K. Mansfield. "The Bursting of Small Cast-Iron Fly-Wheels," by Prof. C. H. Benjamin. A brisk discussion followed this paper, which was participated in by many members, including John Fritz.

A luncheon was served in the building at the close of the session, and the afternoon was left free to members to visit places of interest, to meet socially in the parlors or to attend to other business. In the evening the annual reception and conversazione of members and ladies was held at Sherry's, 44th St. and 5th Ave.

A THIRD BRIDGE OVER THE EAST RIVER, possibly at Blackwell's Island, is advocated by Mayor Van Wyck, and he requests the Board of Public Improvements to take such action, as to location, plans and construction, as may be necessary before the project is submitted to the Municipal Assembly. He recommends crossing over Blackwell's Island. Some complications may arise, as the New York & Long Island Bridge Co. already has a franchise for a bridge at Blackwell's Island. It has built piers on Long Island and Blackwell's Island; but the company is somewhat entangled in the settling up of the Corbin estate, which controls the enterprise. The new assessed valuation of real estate in Greater New York, raising the aggregate by about $400,000,000, seems to have removed the debt limit obstruction, which for a time interfered with raising funds for the East River bridge now under construction.

AN ARC AT THE EQUATOR is to be measured as a result of the Stuttgart conference of the International Geodetic Association, in October. Mr. E. D. Preston, of the U. S. Coast and Geodetic Survey, represented this government at the conference and he will soon make his official report. This arc at the equator, when measured, will be compared with one near the pole, now being measured by the Swedes and Russians; and the comparison will make it possible to determine the difference in length between the polar and equatorial diameters of the earth. Continuous latitude observations, at six stations encircling the earth near the 39th parallel, north latitude, are to be made by six separate nations. The purpose of this observation is to investigate the small periodic changes in the latitude of all places first reported about ten years ago, and to determine the secular motion of the pole. The International Bureau of Weights and Measures, at Paris, reported that a bar made of 36% nickel and 64% steel, was expanded by heat only 1-50th of what would be expected from the separate metals. This is of great importance in the manufacture of astronomical clocks, as it practically eliminates the temperature question.

THE TOTAL IMPORTS OF GOLD INTO THE UNITED States, in the ten months ending Oct. 31, 1898, says the U. S. Bureau of Statistics, was $143,658,095; this is more than 50% in excess of any previous importation in the same period. The exports of gold in this ten months were but $14,061,849, or less than for any similar previous period. This unprecedented flow of gold to the United States is explained by the enormous balance of trade in our favor; the total imports of merchandise, in these ten months, being valued at $527,757,754; while the total export was worth $987,964,356. Out of $1,866,757,783 in circulation in the United States, on Nov. 1, 1898, the sum of $649,846,727 was gold; on Nov. 1, 1895, the gold in circulation amounted to $475,181,593, out of $1,598,859,316 as a total.

EXPORTS OF MANUFACTURED GOODS from the United States, and their phenomenal growth in the past ten years, as compared with the two preceding decades, are well shown by a table just issued by the Bureau of Statistics of the Treasury Department, which we reproduce as follows:

	Total value of exports for fiscal year ending June 30. (1 = 1,000)			
Manufactures.	1868.	1878.	1888.	1898.
Iron and steel.......	$8,352	$16,052	$17,763	$70,367

Glass, etc.	609	869	881	1,211
Brass manufactures..	16	589	308	1,320
Starch	205	605	202	1,371
Soap	626	658	815	1,390
Railway cars	.....	532	826	1,478
Paints, etc.	131	239	492	1,079
Wool manufactures...	206	449	471	1,089

It should be especially noted that the growth in volume of exports is really much larger than the above table shows, for prices have gone steadily downward during the past thirty years. This is especially true of the decade from 1888 to 1898, in which the greatest growth in the value of exports is shown. Besides this, it must be remembered that the value of the exports of 1868 was measured in the paper currency of that date, the value of which was only 71.5% of the value of gold. Hence the growth in volume of exports from 1868 to 1878 was at least 30% more than the above table shows.

THE REPORT OF SECRETARY OF THE INTERIOR Bliss deals with public lands, Indians, pensions, territorial and educational affairs, etc. Mr. Bliss says that of 301,000,000 acres of desert land requiring irrigation, the available water supply is only sufficient for 71,500,000 acres; the remainder is only valuable for grazing purposes. The 30 forest reservations contain an estimated area of 40,719,474 acres. During the year the U. S. Geological Survey made a topographical survey of 30,057 sq. miles; the aggregate now surveyed being equal to about one-fourth of the entire territory of the country, exclusive of Alaska.

THE PROGRESS IN ELECTRICAL SCIENCE was the subject of the late address of William Henry Preece, C. B., F. R. S., on assuming the Presidency of the Institution of Civil Engineers. Mr. Preece was a pupil of Faraday, and for nearly 50 years has been actively engaged in electrical work, and especially in telegraphy. He said that the original line of Cook and Wheatstone, constructed in 1837, and connecting Camden Town and Euston Grove Station, and 1⅓ miles long, had grown to 1,111,366 miles of wire under British control alone. This aggregate covered 435,000 miles for the General Post office; 105,000 miles for railway companies; 387,966 for India and the Colonies, and 183,400 miles of submarine cables. In the United Kingdom alone there are now in use 152,019 telephones, 133,498 of these belong to the National Telephone Co. Mr. Preece recommends the control of the telephone business by the state as in the case of the postal and telegraph service in England. He combats the popular idea that the purchase of the telegraph business in 1869 was a bad bargain for the state. He says the sum paid for it was $24,945,240; the number of messages then sent was about 5,000,000 per year, and the gross annual income was about $2,500,000. This income is now $15,358,615, and over 83,000,000 messages are sent per year; the capital account, closed in 1891, and including Post Office extensions, was $50,656,645; and he says a syndicate now wanting to buy the plant would have to raise a capital of over $150,000,000. In referring to electric lighting, Mr. Preece said that the electrical energy used in a first-class battleship was expended as follows:

	E. HP.
Internal lighting	60
Searchlights	65
Ventilation	30
Capstans, hoists, etc.	60
Reserve	45
Total	260

This quantity supplied 1,000 glow-lamps, 6 searchlights, 16 ventilating fans, and required from 2 to 8 motors. Searchlights were first introduced on warships in 1875, by Mr. Henry Wilde; the first ship fitted with internal electric lighting was the "Inflexible," in 1882. In 1884 the British Admiralty ordered it to be applied to all warships. Electric power was first used on the "Barfleur" for working guns and ammunition hoists. Its use has been partially extended to working gun-turrets, capstans, ventilating fans, boat hoists, etc., but hydraulic power, for these purposes, is still preferred in the British Navy.

◆

A PUBLIC MEMORIAL MEETING, in commemoration of the late Col. George E. Waring was held at the Cooper Union, New York city, on Nov. 23. The City Club, Authors' Club, Century Association and Chamber of Commerce united in arranging for the meeting. Letters were read from prominent citizens and speeches were made by President Low, of Columbia University; Bishop Potter, Reuben Simons, Carl Schurz and Jacob A. Riis. Resolutions were adopted setting forth the services of Colonel Waring as a soldier, citizen and sanitary engineer. The Chamber of Commerce has appointed a committee to raise a fund of $100,000, the income from which is to be paid semi-annually to the widow and daughter of Colonel Waring; and after their death the principal is to go to Columbia University and is to be known as "The Waring Municipal Fund." Thus far about $37,000 has been subscribed.

◆

AN ELEVATOR TRUST, to be called the Otis Elevator Co., says the "New York Commercial," has been formed by consolidating into one company about 90% of the elevator business of the country. The capital of the company will be $10,000,000; $4,000,000 in non-cumulative preferred stock, and $6,000,000 in common stock. Mr. Wm. H. Baldwin, of the Otis Elevator Co., is the chief mover in the enterprise, and will probably be the president of the new company.

◆

BOOK REVIEWS.

BUILDING, CONSTRUCTION AND SUPERINTENDENCE. Part II., Carpenter's Work.—By F. E. Kidder, C. E., Ph. D., Fellow American Institute of Architects, New York, 1898: William T. Comstock, 23 Warren St. Cloth; 6¾ × 9¾ ins.; pp. 544; 524 illustrations. $4.

The first volume of this work appeared in 1896 (Eng. News, Nov. 26, 1896), and was devoted to the treatment of those details of building construction generally coming within the province of the mason. Part II., which is now before us, is of the same size and general make-up, but it has 100 more pages and nearly twice as many illustrations. As indicated in the title, it treats of the carpentry work of building construction, and it is essentially a book for the carpenter and builder rather than for the engineer.

Taking up the contents in somewhat more detail; Chapter I. describes the appearance, quality, ease of working, etc., of the different building and finishing woods of the United States. Among the particular features of this chapter which one notes with most interest are the illustrations and remarks showing the manner in which wood shrinks, and giving the methods of preventing shrinkage. Chapter I. is followed by chapters on wood framing; windows and outside frames; outside wood finish, such as cornices, gutters, gables, porches, etc., shingle roofs and the accompanying metal work; interior woodwork, including furring, interior finish, cabinet work, stairs, flooring, etc. Chapter VI. contains nearly 100 pages on the subject of builders' hardware, covering the construction of locks, hinges, butts, etc., etc. In Chapter VII. the subject of heavy framing in wood is discussed, and we note that the author gives the results of the most recent investigations upon the framing of compound beams which have been made by Prof. Kidwell (Eng. News, March 11, 1897, Feb. 3, March 17, 1898), and others. Chapter VIII. gives forms of specifications for carpenters' work, hardware, trimmings, slate and gravel roofing, tin work, etc.

The book is very profusely illustrated, many of the illustrations being detail drawings of parts of which drawings are not easily obtained. Taken as a whole we do not know of any book on the subject which contains the same amount of up-to-date information, and any young architect or ambitious carpenter would do well to place a copy in his library. The book has a very good index which enables references to be made easily to the different subjects treated.

RAILWAY CONSTRUCTION.—By William Hemingway Mills, M. Inst. C. E., Engineer in Chief of the Great Northern Ry. of Ireland, London, 1898: Longmans, Green & Co. Cloth, 6 × 10 ins.; pp. 364; illustrated; $5.

The American book which this volume most resembles in its character and scope is Mr. Geo. L. Vose's well-known "Manual for Railroad Engineers." It is a far less comprehensive treatise of the subject, however, than the American publication. The detailed information relating to the strength of materials and structures and the typical specifications and standard mathematical formulas given by Mr. Vose are almost entirely omitted by Mr. Mills. The book also describes English practice almost exclusively; the author's references to American practice being few in number and not always very accurate. For these reasons the chief value of the volume to the American engineer will be in the knowledge which it gives him in a broad general way of English practice in railway construction, leaving him to go elsewhere for such information as will qualify him actually to do the work. Keeping these limitations in mind, however, and considering the book as a series of notes upon English practice in railway construction rather than as a treatise upon railway construction in general, as its title indicates, it has considerable usefulness for the American engineer. Doubtless it would fill a much more useful field for the English engineer.

The chapters in detail are: (1) Location of a Line of Railway—Government Regulations—Questions for Consideration in Connection with Gage, Gradients and Curves: (2) Works of Construction; Earthworks, Culverts, Bridges, Foundations, Screw Piles, Cylinders, Caissons, Retaining Walls, and Tunnels; (3) Permanent Way, Rails, Sleepers, Fastenings, and Permanent Way Laying; (4) Station Buildings, Roofs, Lines and Sidings; (5) Sorting Sidings, Turntables, Traversers, Water Tanks and Water Columns; (6) Comparative Weights of Some Types of Modern Locomotives; (7) Signals, Interlocking, Block Telegraph and Electric Train Staff Instruments; (8) Railways of Different Ranks, Progressive Improvements, Growing Tendency for Increased Speeds, with Corresponding Increase in Weight of Permanent Way and Rolling Stock—Electricity as a Motive Power.

UP-TO-DATE AIR-BRAKE CATECHISM.—A complete study of the air-brake equipment, including the latest devices and inventions used. All troubles and peculiarities of the air brake and a practical way to find and remedy them are explained. By Robert H. Blackall, Air-Brake Instructor and Inspector, Delaware & Hudson Canal Co.'s R. R. New York: Norman W. Henly & Co. 12mo, cloth; pp. 230; 40 illustrations. $1.50.

This little book is designed especially for railway trainmen whose duties require a knowledge of the air brake and its methods of operation. The aim has been to make it so elementary and simple that the "green hand" can learn all he needs to know about air-brake work without other aid than this book gives. It is also a valuable textbook for use in the air-brake instruction schools which are carried on by most railway companies. Besides the air brake, the book also gives instructions on the use and care of the air signal. This is the first book for engineers' instruction we have seen which specifically cautions against reversing the engine at the same time the brakes are applied in making an emergency stop.

COMPRESSED AIR PRODUCTION, or the Theory and Practice of Air Compression. By W. L. Saunders. Published by "Compressed Air," 26 Cortlandt St., New York. 8vo, cloth; pp. 58; 27 illustrations.

This book consists chiefly of matter which was published serially in the little monthly journal called "Compressed Air." Mr. Saunders is well known as one of the leading authorities on the subject. His present book is of an elementary nature, entirely free from mathematics; but it presents the fundamental principles governing the production and use of compressed air in a way which can be readily understood, and will prove a useful handbook to those who undertake the installation or management of compressed air plants.

A HANDBOOK OF ENGINEERING LABORATORY PRACTICE. By Richard Addison Smart, M. E., Associate Professor of Experimental Engineering, Purdue University. New York: John Wiley & Sons. London: Chapman & Hall, Limited. Cloth, 12mo; pp. 290. $2.50.

The scope of this book is shown in the following extracts from the preface:

> This volume is intended primarily as a maual for the use of students in the routine of experimental work in Steam-engineering, Strength of Materials, and Hydraulics. It may also serve in a limited way as a guide to those engineers in active service whose familiarity with the ordinary methods of testing is limited. The chief object in view has been to provide in convenient form such directions for the conduct of the various tests and experiments comprising the course as the student will need to enable him to take charge of and conduct the particular work assigned to him in an intelligent manner and with little delay. The methods of testing described under the various general heads are not intended to cover the subject in an exhaustive way. Only such tests have been described as may be carried on in connection with the complement of apparatus to be found in the better equipped laboratories of experimental engineering, and the methods explained are those which the author has found to be most easily employed in every-day practice. Both the manner of arranging apparatus and the method of conducting the tests are capable of great variation to suit the needs of special invesigations.

The author has condensed a great deal of useful information into small space. His style is clear and simple, and his treatment is entirely of a practical nature, avoiding theory almost entirely. The book should prove a useful one to students of mechanical engineering.

THE STORY OF THE RAILROADS.—By Cy. Warman, author of the "Tales of An Engineer," "The Express Messenger," "Snow on the Headlight," etc. New York: D. Appleton & Co. Cloth, 7¾ × 5 ins.; pp. 280; illustrated. $1.50.

This is not an engineering treatise, but a story of engineers, and a very interesting general history of the beginning and completion of the various trans-continental railways. The history of the Union Pacific road commences with the efforts of Asa Whitney, in 1835; but progress really begins with the surveys of the present Gen. Granville M. Dodge, made when in the employ of the Mississippi & Missouri Railway Co., in 1853. The story of the Union Pacific is carried to the completion of that road; and the Atchison, Topeka & Santa Fe, the Denver & Rio Grande, the Northern Pacific, and the Canadian Pacific are then taken up in sequence. Interspersed with the story are many incidents connected with the life and trials of the engineers and workmen engaged in building these roads, and character sketches of the rough social element that drifted West with the iron rails. The book is interesting reading for engineers and valuable for the historical matter which it contains.

PRACTICE AND THEORY OF THE INJECTOR. By Strickland Kneass, C. E., M. Am. Soc. M. E., etc. Second edition, revised and enlarged. New York: John Wiley & Sons; London: Chapman & Hall, Ltd. Cloth, 8vo; pp. 161. $1.50.

Mr. Kneass's book on the injector has been well known, since the issue of the first edition a few years ago, as the standard work on the subject. The new edition contains some new matter, and many changes have been made in the text of the original edition.

THEORY OF ELECTRICAL MEASUREMENTS.—Lecture Notes Prepared for the Third Year Classes of the Cooper Union Night School of Science. By William A. Anthony, Professor of Physics. First edition. New York: John Wiley & Sons. 5 × 7½ ins; cloth; pp. 90. $1.

This little book was prepared by the author for the use of the third year classes of the Cooper Union, New York, Night School of Science, in which he is Professor of Physics. It makes no pretension, of course, to be an elaborate and exhaustive treatise, but it presents the fundamental principles of electrical measurements to the student in a brief but clear manner.

Not the least valuable feature of the book is the series of problems given at the end of each chapter, the correct solution of which is proof that the student correctly understands the preceding text.

A TEXT-BOOK OF GEODETIC ASTRONOMY.—By John F. Hayford, C. E., Assoc. M. Am. Soc. C. E., Expert Computer and Geodesist U. S. Coast and Geodetic Survey. New York: John Wiley & Sons. Cloth; 9 × 5¾ ins.; uu. 351; illustrated.

This work is limited to the treatment of astronomy as applied to surveying, or to geodetic astronomy only. It is primarily a text-book for students, and is made sufficiently short and easy to be mastered by the student of civil engineering in the limited time usually devoted to this branch of study. The simpler and special means of deriving working formulas have been chosen, and considerable space is devoted to the discussion of the various sources of error in each kind of observation, and to the practical handling and adjustments of instruments used. In fact, the five principal chapters in the work separately treat of the sextant, astronomical transit, zenith telescopes and determination of latitude, the azimuth instrument and methods of observing longitude. The aim of the author has been to select formulas which have been found in practice to lead to the most rapid and accurate computations; and to this end he freely uses the larger and standard works of Chauvenet, Doolittle and Loomis, the various reports of the U. S. Coast and Geodetic, Lake, Boundary and other surveys and the practice of those making these reports. It is to be regretted that the illustrative figures used are bunched instead of being distributed through the text, where they belong.

EXPLOSIVE MATERIALS.—The Phenomena and Theories of Explosion, and Classification, Constitution and Preparation of Explosives. By Lieut. John P. Wisser, 1st Artillery, U. S. A. Instructor Department of Military Science, U. S. Artillery School, Editor "Journal U. S. Artillery." Van Nostrand Science Series, No. 70. New York: D. Van Nostrand Co. Boards; 6 × 3¾ ins.; pp. 145. 50 cents.

About fifteen years ago a first edition of this treatise appeared; but the development in this art has been so great in the interval, that the present edition has been entirely rewritten. The result is an entirely up-to-date study of the materials of explosives, the phenomena of explosion, chemical composition, the origin and rapidity of reactions and their propagation, and the products and force of explosion. The various types of explosives are then taken separately and minutely described. The composition and manufacture of smokeless powders is gone into at very considerable length, and forms an unusually interesting portion of the work.

ENGINEERING NEWS
AND
AMERICAN RAILWAY JOURNAL.

VOL. XL. No. 23.

TABLE OF CONTENTS.

ENGINEERING NEWS OF THE WEEK........353, 367
- Progress on the New Water-Works for Cincinnati, O. (with two-page plate and other illustrations).. 354
- A Cooling Tower and Condenser Installation...... 355
- Switches and Frogs for Track of 100-lb. Rails, Duluth & Iron Range R. R. (illustrated)............ 356
- Is it Safer to Run Fast or Slow Over a Weak Bridge? 356
- The New Covered Filter Bed for the Water-Works of Somersworth, N. H. (illustrated).................. 358
- A Universal Circular Saw (illustrated)............. 359
- Tests of Formaldehyde as a Disinfectant at Newton, Mass. 359
- The Hughes Air Lock, Valparaiso Harbor (illustrated).. 362
- New Air Lock and Cylindrical Wooden Pneumatic Caissons for Foundations (illustrated)........... 363
- Between the Mine and the Smelter................ 365
- The Exposure Fire in the Home Life Insurance Co.'s Office Building, New York city (illustrated)...... 366
- Book Reviews 367
- The New York Meeting of the American Society of Mechanical Engineers 368

THE CHESAPEAKE & OHIO CANAL sale is to take place on Feb. 7, 1899, when sealed bids will be opened by the Board of Public Works of Maryland for the entire interest of the state in the canal. This interest consists of a $2,000,000 mortgage made in 1834, and the accrued interest thereon for 64 years, common stock to the amount of $788,724, and preferred stock amounting to $4,375,000. There are some prior liens on the property, amounting to about $2,000,000, which are held by interests friendly to the Baltimore & Ohio R. R. It is generally conceded that the only bidders for the property will be some railway company desiring to use the canal towpath as a roadbed, or the Baltimore & Ohio, which may purchase it to prevent the establishment of a competing line. It is stated that except during the years from 1867 to 1878 the canal has never been a financial success.

THE NEW YORK CANAL INVESTIGATION is again brought to public attention by the report of Hon. Edwin Countryman, who was assigned by Gov. Black last August to make a special study of the testimony taken by the Canal Investigation Commission and to report whether civil or criminal proceedings should be instituted against any persons or public officers by reasons of acts in connection with the canal works. Judge Countryman's report is a voluminous one. He finds in the first place that there is no evidence that any of the contractors were guilty of collusion or fraud in obtaining or carrying out their contracts, and concludes that with two or three possible exceptions there is no chance for a successful suit by the state against the contractors. As regards the State Engineer and the Superintendent of Public Works, however, Judge Countryman holds that, although corrupt collusion with the contractors is not shown on their part, they were guilty of various infractions of law; and he advises that the evidence against both these officials be submitted to the Grand Jury. He holds the State Engineer culpable for not making use of the quantities and information contained in the preliminary surveys in preparing his estimates, and he thinks the reason was that it was desired to conceal from the public the fact that the $9,000,000 appropriation was inadequate to complete the work. The reclassification of earth as rock on various contracts is severely commented upon, together with the means which were adopted to induce subordinate engineers to fix quantities and classify materials in accordance with the instructions of those over them and against their own opinions and measurements.

Concerning the Superintendent of Public Works, Judge Countryman holds that his power and authority were sufficient to have enabled him to have detected and prevented the various illegal acts charged to the State Engineer's department, that he exceeded his powers in the making of special contracts for extra work, and that the application of part of the $9,000,000 appropriation to other work on the canals than the deepening ordered by the legislature was a violation of law.

Concerning the subordinate employees of the departments, Judge Countryman says that while many of them have been shown to be willing assistants in the various illegal practices complained of, he has deemed it best that the public prosecutor should be left at liberty to exercise his discretion in using any of them as witnesses in the prosecution of the principal offenders.

As soon as Judge Countryman's report was made public, Gov. Black instructed the Attorney-General to institute criminal proceedings against the two officials. Superintendent of Public Works Aldridge presented his resignation on Dec. 1.

THE PROBABLE EFFECT OF THE CHICAGO DRAINage Canal upon the water flowing by the communities below its outlet, and especially upon the city of St. Louis, is still causing much discussion in Chicago and St. Louis. A committee of prominent public men has been appointed at St. Louis to investigate the subject, while at Chicago Arthur R. Reynolds, M. D., Commissioner of Health, has addressed a communication to the Trustees of the Sanitary District of Chicago urging that a series of bacterial and chemical examinations be instituted of samples of water collected at various points between Chicago and St. Louis. These examinations would be continued for some years, in order to show the changes wrought by putting the canal in operation.

RIVER POLLUTION BY THE SEWAGE OF MIDDLEborough, Mass., has been pronounced by the State Board of Health of Massachusetts as possibly one of the "causes of the large amount of sickness in the portion of the town which is nearest the river." The board recommends that plans be prepared and carried out for the establishment of a sewage purification plant.

RIVER POLLUTION AT WATERBURY, CONN., has been before the courts more or less of the time since April, 1891, and a new suit, entered upon some two years ago, has just come up for trial after a number of delays. The suit is brought by Platt Bros. & Co. and the Platt Mills Co. against the city of Waterbury. An injunction is sought against the discharge of sewage into the Naugatuck River, and damages are claimed on the ground that the river has been rendered unfit for all uses except power, to which it was formerly put by the plaintiffs.

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred Dec. 2 on the Fitchburg R. R., near Athol, Mass., in which two freight trains collided. The wreck caught fire and a brakeman, who was pinned in the wreck, was burned to death before he could be released.

THE BURSTING OF THE MAIN STEAM PIPE of the Mallory Line steamship "Alamo," on Dec. 3, caused the death of six men and the injury of one other, all belonging to the engineering force. The "Alamo" had been used as a United States troop transport during the recent war and was just starting on her first regular trip South after being thoroughly overhauled and equipped with new boilers and steam pipes. Both had been tested by U. S. government inspectors, and at the time of the accident the boiler pressure was about 80 lbs., while 100 lbs. was the safe allowable pressure. The accident is attributed to the straining of the copper steam pipe at the time it was tested by the government inspectors.

THE EXPLOSION of a part of the refrigerating machinery of the government hospital ship "Bay State," at a dock in Brooklyn, N. Y., on Dec. 6, resulted in the death of the engineer in charge and the injury of a number of hospital attendants. According to reports one of the pipes leading from the ice machine burst, blowing away the bulkhead separating the ice room from the engine room and otherwise damaging the interior of the vessel.

THE EXPLOSION OF ABOUT 10,000 lbs. of powder at Lamotte, Mo., on Nov. 23, killed 6 men and injured several others. According to accounts the explosion occurred in the packing house of the powder mill at that place, and was so severe that its effect was felt fully 25 miles away.

A HARBOR MINE EXPLODED at Fort Independence, Boston, Mass., on Dec. 6, while being hauled from the water's edge to the magazine. Four men were killed, three of them being blown to fragments.

AN ELEVATOR ACCIDENT occurred in a 11-story building at 55 William St., New York city, on Dec. 6, in which one man was killed and three others were seriously injured. It appears that when the car reached the bottom of the shaft the counterweights became displaced and fell from the shaft upon the car.

TWO BASCULE BRIDGES over the Chicago River will be built by the Drainage Board, as they will be cheaper than the construction of by-passes around the old bridges, in order to increase the capacity of flow. One of these will be at Taylor St., and the other will be for the Chicago & Northern Pacific R. R., between Taylor and 12th Sts. The present structures are swing bridges, and both of the new structures will be of the Scherzer rolling-lift type, already in use at three points on the Chicago River. The cost is estimated at $314,000, or $95,000 less than that of the by-pass, while the new bridges will give better facilities for navigation than those at present existing.

TRACKWAYS OR WAGON TRACKS are proposed for use on State St. and Clark St., Chicago, between 16th and 22d Sts., in order to relieve the street railway tracks from the wear and delay to traffic, due to the very heavy wagon traffic at these points. The Chicago City Ry. Co. has to repair the pavements between the streets named, and Mr. M. K. Bowen, President of the company, proposes to use flat rails, 6 ins. wide, slightly concave on top, forming wagon tracks, between the street railway tracks and the sidewalks.

A COMMISSION TO PREPARE A BUILDING CODE for the city of New York has been authorized by the Municipal Council, and the matter is now in Mayor Van Wyck's hands. The ordinance provides for a representative of the Corporation Counsel, the three Commissioners of Buildings, and five experts who shall have had at least five years' actual experience. It is understood that the five experts will be appointed by President Guggenheimer of the Council, and President Woods of the Board of Aldermen.

THE HOLLAND SUBMARINE TORPEDO BOAT has been favorably reported upon by the Board of Inspection and Survey of the Navy Department. The report says that the board found all the claims of the builders verified, but it recommends a further test under "war conditions." This test is to be conducted in about one month over a mile course. In the center of this course an old vessel will be anchored; and the "Holland" must rise to the surface, discharge a torpedo effectively at the hull and then disappear. On the successful accomplishment of this work will depend the acceptance of the boat by the government.

PROPOSALS FOR MACHINERY for rolling armor plate, to be delivered at St. Petersburg, will be received until Dec. 12 at the office of the Naval Attaché of the Russian Embassy, D. T. Mertvago, 818 18th St. N. W., Washington, D. C. A reversing engine is wanted, capable of rolling the ingots to plates at one heat. The rolls are to be 4,000-mm. in length, the maximum weight of ingot 60 tons, and the maximum thickness of the plate is 900 mm. Roller tables lifting appliances, two sets of regenerative furnaces, with movable bottoms, and other appurtenances, are also called for.

A NEW FACTORY FOR MAKING LARGE GUNS is likely to be built at Newport News, in the vicinity of the shipyard at that place. Negotiations are in progress between Mr. C. P. Huntington and Vickers' Sons & Maxim, the English shipbuilding and gun-making firm, for the taking by the firm of a large part of Mr. Huntington's interest in the Newport News company, and for the addition of gun-making to its business. The work on the great dry-dock at the shipyard is advancing rapidly. About 10,000 piles have been driven, and a large part of the excavation has been made.

THE NEW U. S. COALING STATION at Pago Pago, Island of Lutuilla, Samoa, the contract for which was let some time ago to Healy, Tibbitts & Co., of San Francisco, Cal., is being rapidly rushed. The contract for the steel work, amounting to 2,800,000 lbs., has been awarded to the Carnegie Steel Co., and the mills are now at work getting out the material. Contracts are yet to be let for 350,000 lbs. of iron castings, 200 tons of cement and 200,000 ft., B. M., of timber. The coal shed will be 150 × 100 ft., with a framework of steel covered with corrugated galvanized iron. The contractors will take about 40 skilled workmen from America, but will depend upon native laborers for the other help.

THE TROPENAS STEEL PROCESS is about to be adopted by the Union Iron Works of San Francisco. A large foundry is being built, in which will be placed two 2-ton Tropenas converters. Mr. Irving M. Scott, vice-president and general manager of the company, recently made a thorough investigation of the process in operation in Europe. Messrs. Powell & Colné, 11 Broadway, New York city, are the agents for the process in the United States.

A WOODEN SUBMARINE CABLE CONDUIT to carry electric light cables across Fort Point channel, Boston, Mass., was described in "The Electrical Engineer" for Nov. 24. This was constructed by the Boston Electric Light Co. of 6 × 14-in. pine timber grooved on a planer so that when bolted together there were formed 24 circular ducts. The ends are made of oak and are curved up on a 20-ft. radius. The curves were built up of 4-ft. lengths while 20-ft, lengths were used in the straight section. In placing, a trench was dredged across the channel bottom, the conduit was built in two sections and launched; afterwards being joined and weighted until it sank into the trench, and duplicate cables were then drawn in and terminated in separate manholes.

PROGRESS ON THE NEW WATER-WORKS FOR CINCINNATI, O.

(With two-page plate.)

The most comprehensive scheme of water-works improvement now being carried out by a single city in this country is the one at Cincinnati, O. Here work is well under way on a new supply, which will include a river intake pier and tunnel, a primary pumping station, large settling reservoirs, filter plant, clear water basin, long gravity main, second pumping station and a force main to the present distributing reservoir, for all of which $6,500,000 of bonds have been authorized by the legislature.

The need of a new water supply at Cincinnati has long been recognized. The present intake is located on the river front in the heart of the city, below a large number of sewers. The water of the Ohio River at its best is so laden with sediment that few Eastern men or women would tolerate it for a moment, while at its worst it is shunned even by Cincinnatians. The people of Cincinnati, and the West in general, feel very kindly towards the Ohio and Mississippi water, especially when the mud has been removed from it, and speak scornfully of the "vegetable tea" served up by water-works officials in the East. There is some reason for this, for these Western waters, minus their loads of mud, are very palatable. Besides the sewage and mud in the present supply, the old Front St. pumping station at Cincinnati has a far from modern equipment, being sometimes referred to as a museum of pumping machinery.

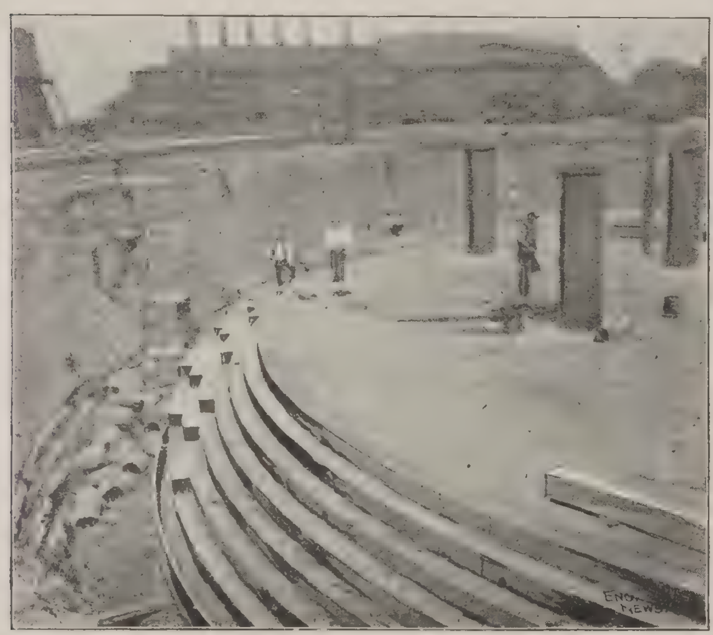

Fig. 9.—Curved Timbers of Triangular Section in Place.

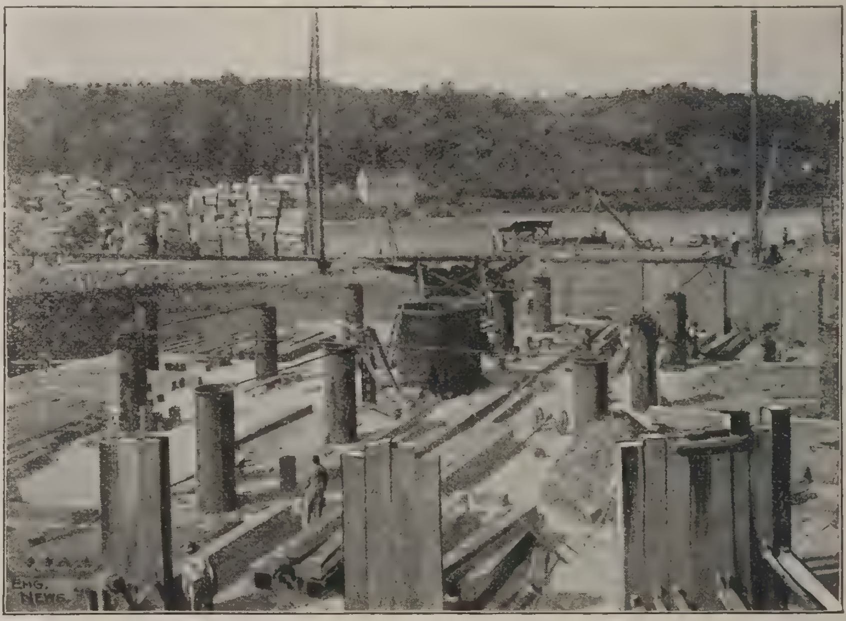

Fig. 10.—Part of Outer Staves and Lining of Central Shaft in Place.

VIEWS OF CAISSON UNDER CONSTRUCTION; THE NEW WATER-WORKS FOR CINCINNATI, OHIO.

In our issue of April 2, 1896, we reviewed briefly a report on a new water supply for Cincinnati, made by Messrs. John W. Hill, Samuel Whinery and Geo. H. Benzenberg, Mems. Am. Soc. C. E., a commission appointed by the Board of Administration of Cincinnati. In its broad general outlines the plan recommended by the commission was similar to that now being carried out, but in its particulars there was much difference. After the appointment of a body officially styled "Board of Trustees, 'Commissioners of Water-Works'," to build new works, the original plans were referred to a new commission for its opinion. The members of this commission were Messrs. Charles Hermany, M. L. Holman, Clemens Herschel, Henry Flad and Samuel M. Felton, Mems. Am. Soc. C. E., and a note giving the main recommendations of its report was published in our issue of May 6, 1897. One of the most significant of the recommendations was that before making designs for a slow sand filtration plant "further investigations be made as to the most advisable method of rendering the water of the Ohio River beyond criticism as to appearance or suspicion as to potability." Mechanical filtration was mentioned as worthy of consideration.

A few days after receiving the report just named the trustees appointed Mr. Gustave Bouscaren, M. Am. Soc. C. E., of Cincinnati, as its chief engineer, and later it selected Mr. Geo. H. Benzenberg, M. Am. Soc. C. E., of Milwaukee, and Mr. Charles Hermany, M. Am. Soc. C. E., of Louisville, as Consulting and Advisory Engineers.

A member of the editorial staff of this journal visited Cincinnati early in October, 1898, saw the work then in progress, and through the courtesy of Mr. Bouscaren, secured the information and material for illustrations from which the remainder of this article has been prepared. It was found that contracts had already been let, as follows: For the intake pier, tunnel and pump pit, to F. H. Kirchner & Co., Cincinnati, who had sublet the pneumatic work to John Monks & Son, of New York city; for grading levee, filter grounds, railway spur and Miami River protection work, to the David Folz Asphalt Paving Co., of Cincinnati; for three 30,000,000-gallon vertical triple expansion pumping engines, boilers and an electric traveling crane at the primary pumping station, to the Lane & Bodley Co., of Cincinnati. Work was already well under way in October on the caisson to be used in sinking the pump pit and on the grading contract. Detailed plans for the pumps had not yet been submitted by the contractors. Experiments, described further on, were in progress to determine the design of the purification works, more especially of the filter plant. The present article will be confined almost wholly to the caisson and the purification experiments.

Description of the Caisson and General Notes on the New Works.

The map, Fig. 1, shows the location of the new intake works in relation to the city and its Kentucky suburbs, while Fig. 2 shows the general plan of the intake, pumping station and purification works. Alternative areas for the filter plant are shown, one for slow sand, the other for mechanical filtration. The river channel here is near the Kentucky shore, necessitating an intake pier in the river and a tunnel with a clear diameter of 7 ft., and a length of about 1,400 ft., as is shown in the plan and profile, Fig. 3. The difference between high and low water in the Ohio River is about 70 ft., which accounts for some of the features of the design of the pumping station, and for the rather unusual appearance of the Covington pumping station, which may be seen on the opposite shore in some of the views. The water will be pumped to two subsiding reservoirs having a combined available capacity of about 345,000,000 gallons, from which it will flow by gravity to the filter plant, and thence to the clear water reservoir and the city pumping station, where it will be repumped to the Eden Park distributing reservoir. The works are being designed for an average daily consumption of 60,000,000 gallons, at the outset, with provisions for a future increase to 80,000,000 or 90,000,000 gallons. Some of the principal elevations of the works will be as follows: Low water at the California, or primary, pumping station, 3.5 ft.; subsiding basins, range, 141 to 110 ft.; clear water basin, range, about 96 to 76 ft.; bottom of well at Pendleton, or second pumping station, about 34 ft.; Eden Park Reservoir, high water, 240.78 ft. The capacity of the Eden Park Reservoir is 100,000,000 gallons.

A cross-section through the California pumping station and pit, showing the caisson at the bottom, is shown by Fig. 4, and the details of the caisson shoe by Fig. 5. The five views, Figs. 6 to 10, show the caisson in its early stages of construction, but before it was completed ready to begin sinking it. The caisson, except for the working cells and air locks, is a solid oak structure, 127 ft. in diameter and 20 ft. high, resting on a steel shoe. It contains about 2,250,000 ft. of oak timber, 12 × 12, 12 × 16, and 12 × 18, every stick of which is planed, and much of which is sawed to special shapes, there being some 15 miles of band saw work on 12-in. oak. Drift bolts, mostly 30 ins. long, 1 to 2 ft. apart, are used vertically and horizontally to such an extent that their combined length would be about 40 miles.

The girders shown in the section, Fig. 4, and in the views, Figs. 6 and 7, divide the lower portion of the caisson into 21 working cells, each 22 ft. square and 8 ft. high, above the level of the cutting edge of the shoe. The cross walls are 3½ ft. thick, including the 3 × 12-in. planking. The inside walls are calked both before and after applying the planking, and the outside walls and the top are calked once. The joints of each horizontal course of timber are grouted with Portland cement and lime, 4 to 1 by weight, after being cleaned with an air blast.

As shown by the views, Figs. 6, 7 and 8, the cross walls, or girders, were first constructed, the first course of roof timbers put on, and then the inclined staves set. After this, the lower, outer part of the caisson was brought to a cylindrical form by adding horizontal timbers, sawed to the proper curves. The inner timbers had their inside faces sawed to fit a conical surface and their outer faces sawed to the radii of the proper circles. These timbers were 12 ins. high, 1½ ins. wide at the bottom, and 13½ ins. at the top. Compressed air was used to bore the holes for the drift bolts and to drive the vertical drift bolts. The pneumatic work and the building of the caisson is in charge of Mr. Daniel E. Moran, M. Am. Soc.

C. E., of and for the sub-contractors, John Monks & Son.

There will be one central shaft, 10 ft. in diameter, which will be the suction shaft, and twelve smaller ones, each 3 ft. in diameter, as shown in some of the views. The latter are the standard shafts for Moran air locks.

All shafts are lined with steel, the plates of the large shaft being ¾-in., and of the small shafts about ¼-in. thick. The caisson is to be sunk to a depth of about 87 ft. below the surface of the ground. The working cells will be refilled with the best sand found in making the excavation, and the air lock shafts will be filled with concrete. The central shaft will then be carried on down to rock, about 18 ft., and continued in the rock to the level of the intake tunnel, the height from the bottom of the shoe to the center line of the tunnel being about 46 ft. The central shaft and the pump house walls will also be extended upwards from the top of the caisson, as shown in Fig. 4. A special feature of the outer masonry wall will be a ¼-in. steel cylinder built into it to make it water-tight. Mr. Alfred Petry, M. Am. Soc. C. E., is resident engineer on the work now in progress at California.

The intake tunnel is designed for a self-cleansing velocity of 3 ft. per sec. It is to be lined with two rings of brick, backed with concrete.

The subsiding reservoirs will be operated on the fill and draw plan. Each basin will be alternately pumped into and drawn from for from 72 to 48 hours at a time, giving an average subsidence of 72 hours for a daily output of 57,500,000 gallons; 60 hours for 69,000,000 gallons; and 48 hours for 86,250,000 gallons. Grounds have been provided for the construction, when needed, of a third settling basin, at the same elevation as the others, with a capacity of about 120,000,000 gallons.

The reservoirs will be formed by damming ravines, thus giving them the irregular shapes shown on the plan, Fig. 2. This irregularity makes the continuous settling plan impracticable, owing to uncertainties regarding the circulation of the water. The embankments will be built by what Mr. Bouscaren terms the dry process, that is, in 4-in. layers rolled dry with heavy steam rollers. In wet weather work on the embankments will stop. Four years is allowed for building these reservoirs. A similar plan of construction was employed by Mr. Bouscaren on the subsiding reservoirs for Covington, Ky., which are right across the river from the new works for Cincinnati. The Covington intake is close by the location chosen for Cincinnati, so the water for the two cities, as drawn from the river, will be identical in character. This fact has interest because some thirty days of sedimentation in the Covington reservoirs effects a large removal of bacteria and sediment, but even this long period of quiescence does not produce an ideal water. Thirty days sedimentation for Cincinnati, with the proposed ultimate capacity of 90,000,000 gallons, would mean duplicate settling basins of 2,700,000,000 gallons each.

The clear water basin will be 20 ft. deep, 400 ft. sq., and have a capacity of 20,000,000 gallons. As it will contain only about an eight hours' supply it is not thought necessary to cover it.

The final location and character of the conduit to the city pumping station had not been decided up to Nov. 20. Its length will be about 23,000 ft.

A toll road passed through the land bought for the new purification works. To divert the traffic, and to save paying tolls, the trustees have bought about a mile of this turnpike, and are constructing a piece of new road. They have also made a contract with a railway for changing its track from narrow to standard gage. A spur about 5,000 ft long will be built by the city from the railway to the pumping station. This will be available for the use of the contractors. It will include a viaduct 630 ft. long, on an 8½° curve, composed of plate girders of alternate 30 and 60-ft. spans.

The five trustees of the new works are: Aug. Herrmann, President; Maurice J. Freiberg, Chas. M. Holloway, Leopold Markbreit and Wm. B. Melish.

The Cincinnati Experiments on Water Purification.

In November, 1897, the chief and advisory engineers submitted a recommendation that water purification experiments be instituted, they being

> confronted with the fact that there is not sufficient reliable information or experience at hand regarding the best and most economical methods to be adopted for filtering th Ohio River water.

The engineers did not doubt the success of slow sand filtration abroad, but they said that the water there differed materially from that of the Ohio for at least six months of the year. They also desired information to enable them to decide between slow sand and mechanical filtration, and more light on sedimentation. They considered that it would be wise to spend in experimental work 3% of the estimated cost of a purification plant and advised

> the construction of settling tanks and filters of sufficient capacity to purify Ohio River water at the rate of 250,000 gallons per 24 hours for a period of eight months.

Mr. Bouscaren estimated that the desired experimental work could be carried out at a cost of $23,000 for construction, and $9,000 for operation for eight months. Mr. Geo. W. Fuller, who had just finished his experimental work on water purification at Louisville, was engaged as chief chemist and bacteriologist to take direct charge of the Cincinnati tests. On March 28, 1898 the experimental plant at Cincinnati was put in operation, and it, as a whole, has not shut down since, running days, nights and Sundays. It is expected that the experiments will be continued until at least Jan. 1. The following information regarding the scope of the experiments, and the factors involved, were obtained from Mr. Fuller.

The drainage area of the Ohio River above the new intake is about 71,000 sq. miles. The turbidity of the water ranges from 5 to 2,500 parts per 1,000,000 of total matter in suspension, by weight. The minimum amount of suspended matter is practically all clay, while of the maximum a large percentage is silt and coarse clay, suspended matters in the water being divided conventionally into sand, silt and clay, according to their hydraulic subsiding value. Between the limits named there are all sorts of variations and combinations in the amount and character of the suspended matter. This will be better appreciated on noting that the drainage area of the Ohio includes many variations in surface geology, and that the rainfall and runoff causing increases in turbidity may cover the whole drainage area, or any of its several sections having different geological formations. The maximum turbidity may occur several times in a year. As compared with the Merrimac River at Lawrence, water from which has been used for the Massachusetts experiments on slow sand filtration, the turbidity of the Ohio River is enormous, for, while at rare intervals, say, perhaps, four or five times in a century, the Merrimac River in freshet may carry 1,100 parts of suspended matter (silt), there is generally so little that chemists do not take the trouble to determine it. The bacteria in the Ohio River water range from 1,000 to 100,000 per cu. cm., with an average of about 10,000. The suspended organic matter ranges proportionately with the total suspended matter, but of the fairly constant dissolved organic matter it is hard to distinguish between that of sewage origin and that washed from the surface of the earth.

The experiment station at Cincinnati is located immediately below the retaining wall of the Eden Park Reservoir, so water may be taken from the force main leading from the main pumping station and pass through the purification plant by gravity. This secures water as nearly as possible like that of the river, at the intake of the present pumping station. The unit basis of the plant being a daily capacity of 100,000 gallons, four settling tanks, each of that available capacity, were provided and are used in rotation. These are of steel, 25 ft. in diameter, and 34 ft. high. They are designed for quiescent subsidence, being filled from the bottom and emptied through valves placed at different levels, the upper valves in succession being opened first. The average total subsidence is designed to be three days, figured from the time the tank is full until it is half empty. It takes about four hours to fill each settling tank.

The water passes by gravity from the settling tanks to an equalizing tank, in which it is held automatically at an approximately constant level. From this box the water flows through valves kept wide open, for constant flow, to the top of the filter beds, which are all at the same level.

There are 15 wooden tanks used for filter beds, in three sets, of five each. The diameter of each tank is 11.78 ft., or 1-400 acre. In each set of five tanks one is 10 ft. deep, three 8 ft. and one 6 ft., the shallower tanks being blocked up to bring the tops all to the same level. Each of the 15 tanks has gravel layers at the bottom for supporting the filtering sand, similar to those at the Lawrence Experiment Station. The 10-ft. tanks contain 5 ft. of filterng sand; the 8-ft., 3 ft.; the 6-ft., 1 ft. The available water space above the sand in each tank is 4 ft., before the depth of the sand is decreased by scraping. To prevent the water from rushing down the sides of the tanks in channels there is a series of horizontal grooves about 1¼ in. wide and ⅝-in. deep, 6 ins. c. to c. They seem to be successful. Each set of five filter tanks is filled with coarse, medium and fine sand, with effective sizes of 0.34, 0.27 and 0.20 mm., respectively. The sand was taken from the bed of the river, in the vicinity of the site for the new works. The inlets to the filter tanks enter at the sides, about 2 ins. above the original sand surface. The filtered water is drawn from the bottom of the tanks, near the sides. The outlet pipes extend to a meter room beneath the filter platform, there being a meter for each filter. On each outlet pipe there are two valves, one close to the tank, which is kept wide open, and one in the meter room, which is used to regulate the rate of filtration.

All the filters operate on the continuous plan. The rates of operation, for each set of five, are, three at 2,600,000 gallons acres per day, these having, respectively, 5, 3 and 1 ft. of filtering sand; one at 4,000,000, and one at 1,500,000 gallons, each having 3 ft. of sand.

The laboratory is a temporary one-story building, of wood, about 30 x 65 ft. It contains a full chemical and bacteriological equipment. Besides Mr. Fuller, who is Chief Chemist and Bacteriologist, there are six trained assistants, three of whom, ranking as first assistants in their respective departments, were with Mr. Fuller on the Louisville work, as follows: Chas. L. Parmelee, Engineer; Jos. W. Ellms, Chemist; Geo. A. Johnson, Bacteriologist.

As to the results of the experiments it is not fitting to speak, in view of their present uncompleted state, further than to say that on the whole satisfactory progress is being made, and that the bacteria are more easily removed than the turbidity. This last is not surprising, in view of the fact that at times the particles of clay in suspension are much smaller than the bacteria. When the Cincinnati report is published we shall have for the first time, so far as we know, detailed information regarding the possibilities of combined sedimentation and slow sand filtration for the removal of bacteria and turbidity from a water liable to be frequently high in both.

A COOLING TOWER AND CONDENSER INSTALLATION.*

By J. H. Vail.†

The conditions existing prior to the installation of the plant referred to in the following paper were as follows: The electric light station was equipped with 27 boilers, 48 ins. in diameter, 20 ft. long, with 22 5-in. tubes. The engine capacity and the load on the station already taxed all the boilers to the limit of their steaming capacity.

Plans had been prepared and estimates made for enlarging the building and increasing the boiler capacity.

After an investigation of the existing conditions, the writer recommended that by the putting in of a cooling tower and a condensing system, the engine capacity of the station could be increased, leaving the boiler capacity the same, thus saving the cost of adding more boilers and enlarging the building, and at the same time obtain better economy, as well as a greater capacity for production.

To determine the steaming capacity of the boilers, two tests were made with one pair of boilers, which showed that under regular working conditions, with Shenandoah pea coal, each 48-in. by 20-ft. boiler would evaporate into steam 4,281 lbs. of water per hour, giving a capacity of 115,587 lbs. steam per hour with every boiler in operation. Coincident with the boiler test, one 18½ x 30-in. Buckeye engine was using the steam from the boilers under test. The result from the engine test and average of all cards showed a steam consumption of 46.8 lbs. steam per I. HP. per hour. [This high figure is no doubt largely due to extremely variable loads.—Ed.]

---

*Condensed from a paper presented at the New York meeting of the American Society of Mechanical Engineers.

†Chief Engineer Pennsylvania Heat, Light & Power Co., Philadelphia, Pa.

The writer recommended that the Buckeye engine should be converted from the 18½ × 30-in. hugh pressure engine into a 14¼ and 25 × 30 tandem compound condensing engine. Also that an additional 750-HP. tandem compound condensing engine should be erected in the station, together with a cooling tower and the necessary condenser equipment, and that the only change in boilers should be to raise the working pressure. No increase of boiler capacity has been made.

After investigation, the Barnard type of cooling tower was selected as desirable to best meet the conditions existing at this plant, which were, minimum floor space, and minimum weight, and a considerable elevation above floor level of engine room.

Details of Cooling Tower.

The cooling tower is of the twin type, having two chambers, with a pair of fans supplying a strong draft of air to each chamber. The interior dimensions are 12 ft. 3 ins. by 18 ft. by 29 ft. 6 ins. high. The shell of the tower is of steel, 3-16 and ¼-in. plates, reinforced with angle and channel irons.

The hot water from the condenser discharge is delivered through a 10-in. wrought-iron pipe, extending the whole length of each chamber, slotted on top, and perforated at the bottom, giving equal distribution to a series of 96 distributing pipes, extending across the tower, each pipe being slotted and perforated, thus insuring a very uniform distribution of water.

Means are provided for cleaning these pipes, which is found necessary in cold weather, when the cylinder oil from the exhaust steam is liable to clog the pipes and interfere with uniform and free distribution of the water.

The hot water falls from the distributing pipes over 42 galvanized wire mats, made of No. 19 steel wire, woven to No. 5 mesh. Each mat is 12 ft. by 15 ft. 6 ins., affording a total of 8,064 sq. ft. of cooling surface. Each mat is suspended by galvanized iron hooks, and is easily removed for cleaning or repairs. In actual service it is found that the water is uniformly distributed.

The circulation of air is furnished by two pairs of 8-ft. diameter fans, each pair of fans being mounted right and left on a 2 15-16-in. shaft, and the four fans being capable of delivering 360,000 cu. ft. of air per minute when driven at a speed of 150 revolutions per minute. The air entering the tower chambers at the lower section is deflected vertically from each fan, thus avoiding cross currents, and affording a uniform blast through and between the mats.

The rated capacity of each section of this cooling tower is to cool the circulating water needed to condense 12,500 lbs. of exhaust steam, from an initial temperature of 132° F. to 80° F. when the atmospheric temperature does not exceed 75° F., nor the humidity 85%.

The circulating water is handled by a Blake vertical twin air pump and jet condenser.

In an equipment of this kind it is important to have facilities for driving the fans at variable speeds; this requisite flexibility has been obtained by using a small vertical engine without a governor direct connected to the shaft of each pair of fans.

The accompanying table, extracted from the log records for many months, shows details as to temperatures, speed of fans, reduction of temperature of condenser discharge, etc.

As previously noted, the 18½ by 30 Buckeye engine was changed to a 14½ and 25 by 30 tandem compound condensing engine by bolting new tandem cylinders on the existing frame and making necessary alterations in valve rods, etc.

Specimen cards, taken from this engine as in daily service, give the following data:

Revolutions, 137; steam pressure, 113 lbs.; mean effective pressure, 50.16 lbs.; vacuum per gage, 26 ins.; I. HP. developed in high pressure cylinder, 163.42; I. HP. in low pressure cylinder, 168.48—total, 331.9 HP., and of this 90.52 HP. is below atmospheric line. The work is divided almost equally between the high-pressure and low-pressure cylinders; all cards show similar results.

In addition to the tandem Buckeye engine a tandem compound condensing engine, 20 and 36 by 42 ins., 120 revolutions per minute, Corliss type, built by Pennsylvania Iron Works, was installed to drive a direct-connected Stanley 500-K-W. two-phase A. C. generator. This engine works 15 to 17 hours per day.

The usual work required from the cooling tower and condenser varies from 7 to 17 hours per day. A notable record was made on Aug. 2, 1898, when the run was from 7 a. m. till 12 midnight, and from the daily records, the following data are extracted:

	Maximum.	Minimum.
Temperature, atmosphere	103°	83°
Temperature, condenser discharge to tower	128°	106°
Temperature, condenser suction	98°	91°
Degrees of heat extracted, through tower	32°	21°
Speed of fans, revolutions per minute	160	140
Vacuum at condenser	26	20
Strokes of condenser pump	50	38
Pounds boiler pressure	121	100
Temperature, boiler feed	212°	200°
Engine, HP. developed	900	400

A continuous heavy load was carried during the entire 17 hours' run. This was not a test record, but simply daily service.

Indicator diagrams, Nov. 5, 1898, from the 20 and 36 × 42 tandem compound condensing Corliss engine, gave the following:

Engine revolutions	120 per min.
Steam pressure	112 lbs.
Vacuum at condenser	25 ins.
Work done in high-pressure cylinder	311.8 HP.
And in low-pressure cylinder	31.5 HP.
	643.3 HP.
Work done in low-pressure cylinder below atmospheric line	185.1 HP.

Simultaneously with the engine, the pump and fan engines were indicated. The cards showed:

Work done by the pump	13.75 HP.
Work done by the fan engines	13.5 HP.
Total external work	27.25 HP.

which if deducted from the work done below atmospheric line in low-pressure cylinder 185.1 HP. leaves a net gain of 157.85 HP. from the use of the condenser and cooling tower.

It will be noticed from the previous data that the feed water shows a temperature above 200° F. There are two feed-water heaters in connection with the condensing plant. First, an intermediate tubular heater in the line of exhaust between low-pressure cylinders and condenser. Second, an auxiliary feed-water heater was also attached, receiving the exhaust from the condenser and boiler feed pumps, and any other auxiliaries.

The feed water is first heated in a tank that receives the exhaust from the general line of high-pressure engines. The feed water then passes through the intermediate heater, and thence through the auxiliary heater, and reaches the boiler at a temperature of upwards 200° F.

The condensing plant has increased the station capacity about 1,000 HP. with the aid of a condensing system, using the same water in continuous circulation, while the boiler plant, previously stated to be fully loaded, supplies steam for this additional work with boilers to spare.

	1898.

SWITCHES AND FROGS FOR TRACK OF 100-LB. RAILS; DULUTH AND IRON RANGE R. R.

The use of 100-lb. rails is not yet so extensive but that switches and frogs built up of such rails have a sufficiently striking appearance to attract attention from and be of interest to the users and makers of track equipment, and it is interesting to note that equipment of this kind is now being introduced on the Duluth & Iron Range R. R. The present track of this road is laid with 80-lb. rails, but we learn from Mr. R. Angst, Chief Engineer, that his road is now laying about 4,000 tons of 100-lb. rails (of the section recommended by the rail committee of the American Society of Civil Engineers), and has adopted standard plans for the switches and frogs, as shown in the accompanying drawings.

The switch, Fig. 1, has switch rails 20 ft. long, the throw at the toe being 5 ins., and the width over gage lines at heel, 6½ ins. These rails are connected by five tie rods ¾ × 2½ ins., the ends of which are fitted into sockets in large heads bolted to the rails. The front rod is 9 ins. from the toe, and the rods are spaced 38 ins. c. to c. Near the ends, the switch rails are stiffened by reinforcing bars ⅝ × 3 × 81 ins., each bar being secured to the outside of the web of the rail by ⅝-in. rivets. The ties are spaced 19¼ ins. c. to c., except that those at the heel and toe are 17 ins. and 18½ ins. apart, respectively. On every tie are tie plates or slide plates for the switch rails, and rail braces outside the stock rails. The plates vary in size from 6 × 19½ ins. to 5 × 9 ins., the former being ⅜-in. thick, with slide seats raised 7-16-in., while the smaller plates range from ⅜-in. to 3-16-in. in thickness.

The frogs are of the spring rail type, as shown in Fig. 2, which represents a No. 10 frog. The frog is riveted to a ¾-in. plate, 7 ft. long, and 19 ins. and 27 ins. wide at the ends, on which are the springs, guides and anti-creeping attachment. The main rail is carried to the point, its end being beveled, and 5 ins. from the theoretical point, having a thickness of 7-16-in. The heel block, or raising block, is either a steel casting or an inverted piece of the rail planed to shape. Wooden footguards are fitted to the throat, and at the ends of the spring and wing rails. The frog is 15 ft. 11 ins. long over all, and has a spread of 7⅞ ins. at the mouth and 5½ ins. at the heel, while the width of throat and flangeway is 2 ins. The connections to the lead rails are made with six-bolt splice bars. The movable rail is held by double coiled springs, placed at the throat, 12 ins. from the point. The frog rests on ten ties, 19 ins. c. to c., the toe being over the sixth tie from the heel.

Perhaps the most interesting feature of all, however, and one which is certainly novel, is the use of a heavy angle iron instead of the usual piece of track rail for the frog-guard rail, as shown in Fig. 3. This guard rail is made from a piece of commercial angle iron ¾ × 6 × 6 ins., 20 ft. long. It gives a flangeway 1¾ ins. wide for 8 ft., and then flares out to an entrance width of 4½ ins. The guard rail is fastened to the ties by spikes in ¾-in. square holes, and is secured to the track rail by seven ⅞-in. bolts with cast spacing pieces or fillers. This arrangement reduces the field work on the metal to the drilling of a few holes in the main rails, makes a neat job, and ensures uniformity.

The switch rails, frog and frog guard rails for each turnout are ordered in one lot.

FIG. 1.—SWITCH WITH 100-LB. RAILS; DULUTH & IRON RANGE R. R.
R. Angst, Chief Engineer.

IS IT SAFER TO RUN FAST OR SLOW OVER A WEAK BRIDGE?

The precaution most commonly adopted to avoid accident in the case of a weak railway bridge is to reduce the speed of crossing trains. The wisdom of this practice can hardly be questioned when we consider all the conditions in the majority of cases, but occasionally the question arises whether in a particular case it would not have been safer to reverse the ordinary practice and cross the weak structure at high speed. A query of this character has recently been brought to our attention by a well-known engineer who gives it his own answer, and states the reasons upon which that answer is based in the following interesting communication. We shall be glad to give space to the narration of similar incidents of trains jumping weakened bridges by any of our readers who may have observed the circumstances. Our correspondent writes as follows:

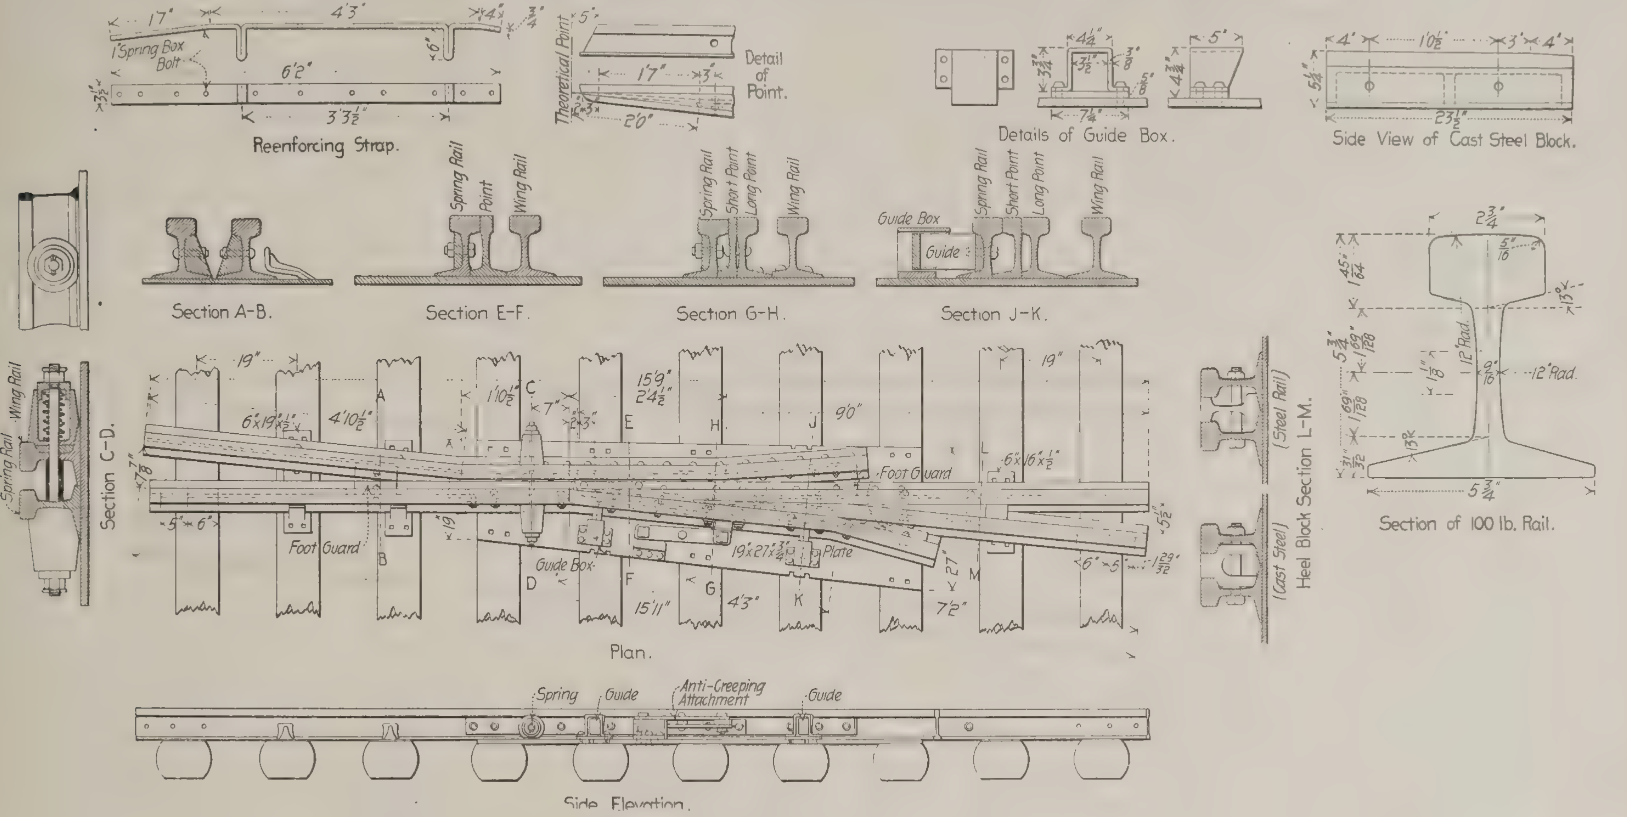

FIG. 2.—NO. 10 SPRING-RAIL FROG WITH 100-LB. RAILS; D. & I. R. R. R.

I believe it possible, if not probable, for a passenger engine running 50 or more miles per hour, actually to leap a clear opening of say not over one-third its stiff-frame length. I would not care to be on the engine, but still I believe such an occurrence is possible. The "leaps" on which I base my opinion were not over clear openings, but over structures that had none or little supports other than the track rails, strength of bolster bolts and stiffness of bolsters (or corbels), stringers and undermined masonry. Though the following trains in each case were wrecked, yet, had their engines been running light at the time, the engines would not have even left the rails but have passed on in safety. These are all authentic occurrences as the newspapers of the dates, the trials in the courts, and the records of the several roads will verify, and I was the Chief Engineer of the roads at the time.

The Blue River accident was at Salem, Ind, and my memory is that the bridge consisted of four spans of 18 ft. (total length, 72 ft.), made up of two new oak stringers, 12 × 16 ins., under each rail, long bolsters of the same size crossing each pier, having 1-in. bolts. All the piers, three in number, were entirely washed out and gone. The engine crossed and stopped (off the rails) safely, and I think, uninjured, on the top of the embankment at the south end of the span.

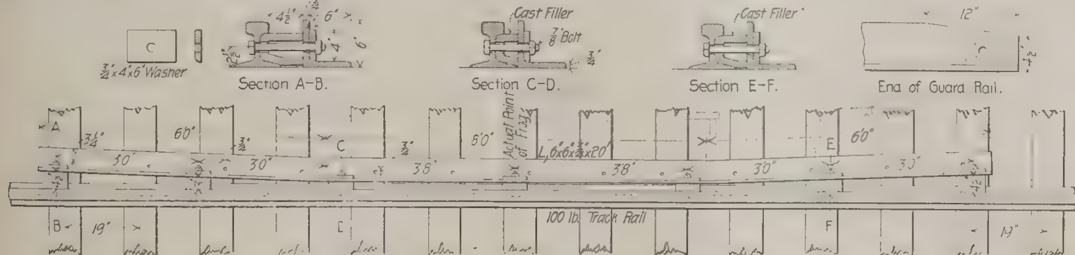

FIG. 3.—ANGLE IRON GUARD RAIL FOR FROGS WITH 100-LB. RAILS; D. & I. R. R. R.

The White River bridge at Broad Ripple, near Indianapolis, had two spans of Howe truss, about 100 ft. long each. We were putting in new stronger end rods in the south end of the north span and moving the old rods towards the center, throwing away the old center rods. The foreman (a smart Alec), against orders, permitted an accommodation train, going south, to run onto this span while only the four temporary 2½-in. diameter construction rods were in, instead of the six new 2-in. rods, which he was just preparing to put in. One of these 2½-in. rods broke. The span broke in two at the north end of the first south panel. The locomotive went over safely, stopped, just off the rails, on the north end of the south span, and was not injured. Both these accidents occurred between 1881 and 1885, and Engineering News, I am sure, gave an account of them.

The Ten-Mile bridge accident, on the Louisville, Cincinnati & Lexington R. R. (Cincinnati Branch), occurred so long ago (between 1875 and 1881) that I have forgotten whether it was two 100-ft. spans of Fink trusses or only one. I think it was two. However, the center pier or one of the abutments was undermined and fell while a train was on the bridge. The engine in this case also went over safely and stopped on the embankment near the bridge.

A few miles north of Crawfordsville, Ind., a light engine I was on, was flagged by the carpenter foreman just as we rounded a curve. The engineer reversed and when we stopped the center of the engine was exactly over a 10-ft. opening. The engine was going north and the north end of the stringers were entirely unsupported by anything, the embankment bent having fallen out.

At the Wea trestle, a few miles south of Lafayette, Ind. (spans c. to c. of bents 15 ft., stringers 15 ft. long, two under each rail, I think, 10 × 16 ins., with bolsters of the same size and about 8 ft. long, bolted with 1-in. bolts through the bolsters and stringers at each end of the bolsters, the stringers being 15 ft. long and cut off over each bent), a freshet at night washed entirely away the second bent at the north end. The Superintendent of Bridges was sent by me to see what damage the freshet had done, if any, as the last engineer over the trestle reported something wrong. The superintendent and all his men with him, after repairing the rocks misplaced at the embankment end, reported the trestle safe—did not miss the missing bent. The engine drivers for a week reported "track not good at Wea trestle," but said it was only a "little rough." The section foreman, who crossed every day and who had repaired the surface at the north end, also reported everything safe. A week after the freshet I went to Lafayette, took a "hog," and with the roadmaster, went to the trestle, went below, to one side where I could see the whole trestle, took a look; asked the roadmaster if he thought the trestle safe, who answered, "Yes." I told him I did not think so as one bent was gone, and pointed to the space. The "hog," waiting for us to get through looking at the trestle, was standing with its tender on the embankment and the pilot over the lost bent space. I motioned the engineer to back up slowly, and he moved his engine onto solid ground. Politics (?) retained the bridge superintendent and roadmaster, but I could and did fire the section foreman who lived near by and saw the trestle twice a day. I wanted to fire the other two but could not. Every train on this division of the road passed over this 30-ft. opening supported by the rails, and eight 1-in. bolster bolts only, for a week, and the only report from the engine-men was that "track was rough on Wea trestle."

The White River bridge, consisting of three spans of Howe trusses, over 100 ft. each (I think 110 or 120 ft.) between Mitchell and Bedford, Ind., had been inspected(?) once a year for 20 years regularly, and probably once a month irregularly, during these years, and always reported sound and safe. I inspected it myself and after removing the weatherboards—snow protection—on the inside of the east truss at the north end of the north span, I found under the end of the end braces and posts that the bottom chord was entirely eaten away by ants. This truss of this span, for no one knows how many of the 20 years, had sustained itself and the live loads by "force of habit" for there appeared nothing else to do it.

All these bridges (and trestles) were located where trains ran fast. In four of the cases engines went over safely, and in the others trains did so.

The question then which comes directly to my mind is, is it not a fact that gravity can to a very considerable extent be overcome by the momentum of swiftly moving trains, and in short spans, say 30 ft. and under, is there not an excess of factor of safety generally used by engineers in designing such spans? I fully approve of using the excess, but I think that a similar excess should be used as well, in long spans, though this adds to cost, on the theory that it is money well spent when spent on the side of safety. But this does not change the question in my mind as to how much impact, weight, gravity, or whatever it may be called, does a rapidly moving rolling object put upon a structure or track. This subject has all come about by my being called upon as a witness in a case of a trestle falling where everything went into the "hole" but the engine, which went over safely. Under oath I was asked: "Which would you consider safest, to pass over a structure (like the one in question whose spans were only 12½ ft., the stringers 25 ft. long, packed to break joint over bents, and composed of two piers of 9 × 16-in. yellow pine) where one of the bents is badly decayed, at a fast rate of speed, or at a slow rate of speed?" I answered I would rather risk my life on the fast train. The reason? I have already stated it. In conclusion, I would very much like to hear of the experience of others on this subject. We learn by experience of others, but some are afraid to tell their experience. I am not, for if I am wrong on any of my theories I want to be corrected as soon as possible before I make a mistake that will ruin the company or kill its patrons. Experiences, as well as appearances, sometimes are deceiving.

THE NEW COVERED FILTER BED FOR THE WATER-WORKS OF SOMERSWORTH, N. H.

The second slow sand filtration plant built in this country and covered with a masonry roof is located at Somersworth, N. H. This filter was put in operation about April, 1898. Like the filter beds at Ashland, Wis., described in our issue of Nov. 25, 1897, the Somersworth plant was designed and constructed by Mr. Wm. Wheeler, M. Am. Soc. C. E., of 89 State St., Boston, and, like the earlier plant, this one also has an area of one-half acre.

The population of Somersworth was 6,207 in 1890, and is about 7,000 at present. From 1864 to 1896 the water supply was furnished by the Great Falls Manufacturing Co. In 1896 the city bought the distributing system, except the portion supplying the property of the company. This portion, together with the old pumping plant, reservoir and stand-pipe, the company retained for the supply if its mills.

The water delivered by the company was taken from the Salmon Falls River, at a point below one of its mills and also below a part of the town. This water was sometimes objectionable to sight and taste, and quite a strong feeling against it developed. In the discussion leading up to the establishment of municipal works the general desire seemed to be to substitute spring or well water for the river supply, but attempts to find such in suitable quantities failed. Of the available surface supplies, chemical analyses and physical examinations indicated that the Salmon Falls River, at a point above the city, would be the best source. A description of this source, accompanying a sample sent by Mr. Wheeler to Dr. Edw. S. Wood, of the Harvard Medical School, for analysis, gives the following information:

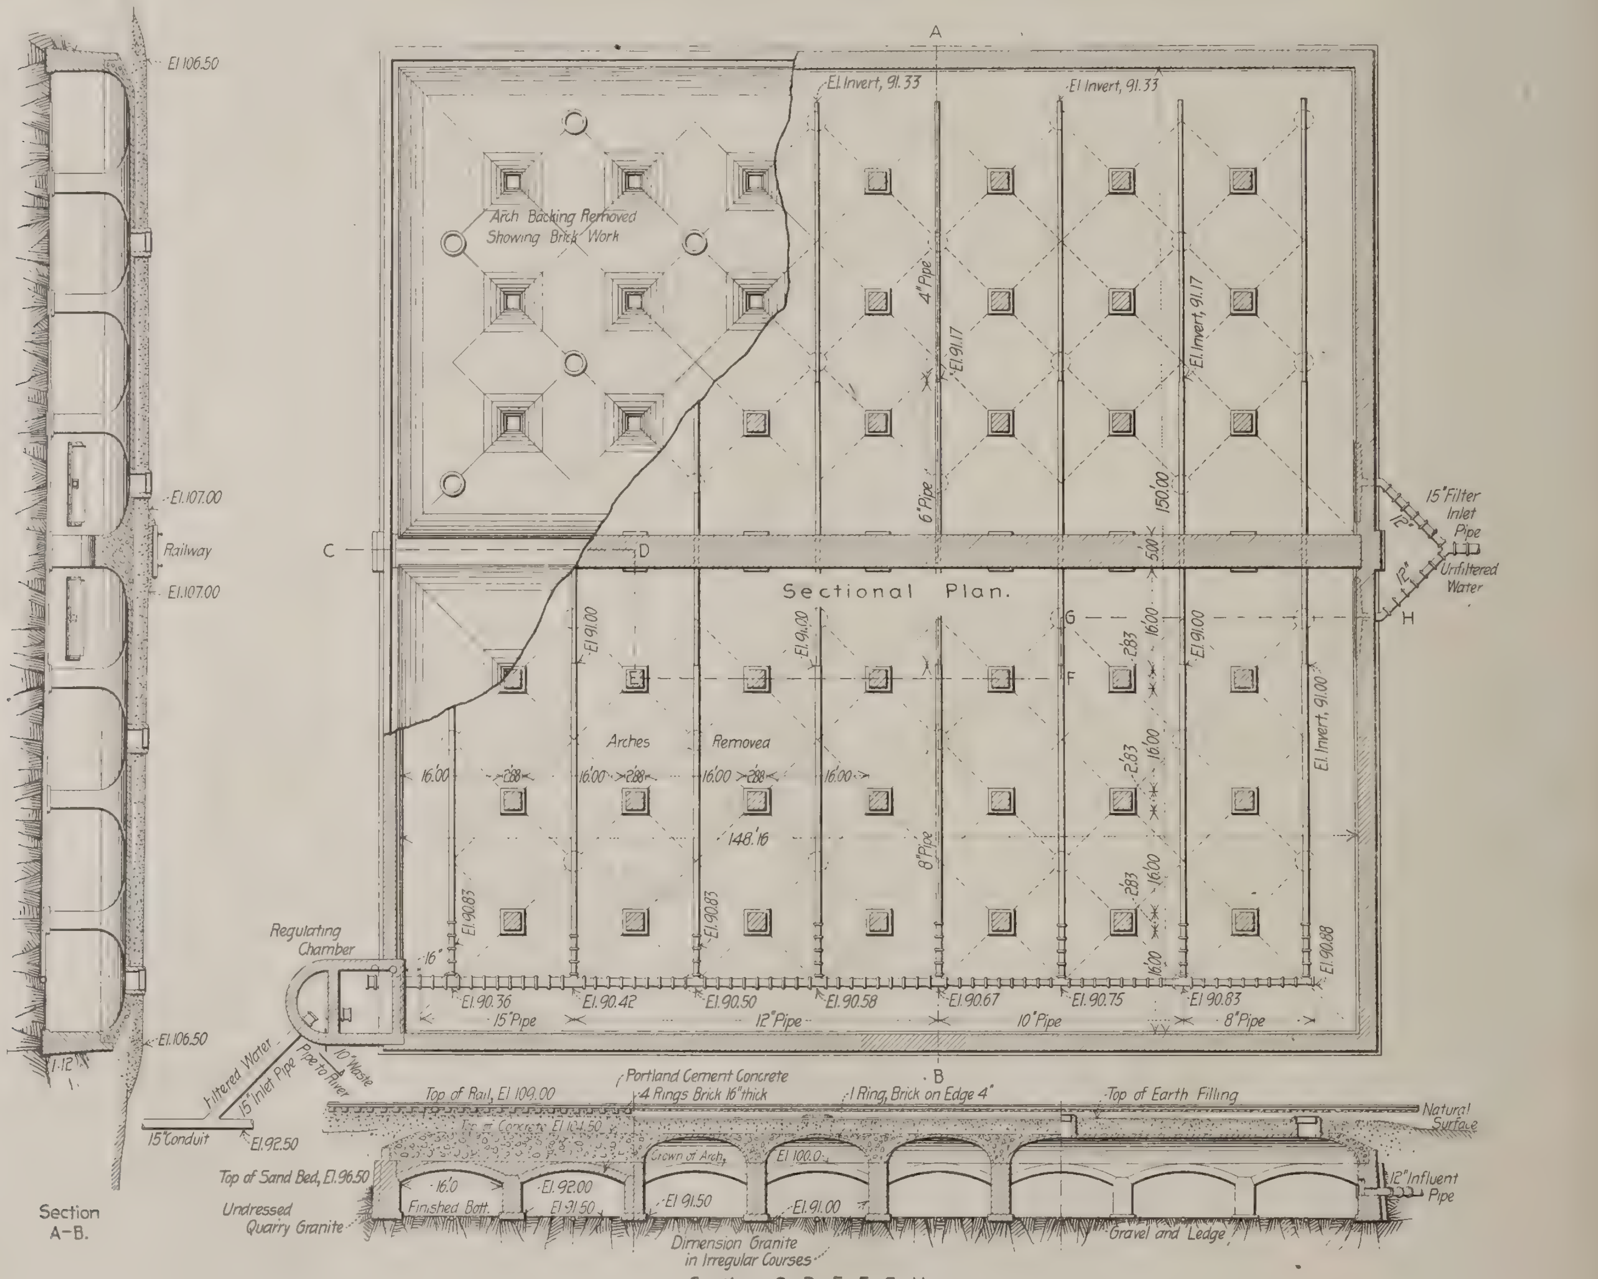
> Salmon Falls River has its source in Great East Pond in Acton and Wakefield, 18 miles distant. Only two places on river above here, Milton (14 miles distant), about 1,000 inhabitants, and East Rochester, about 1,500 inhabitants, 7 miles distant. After leaving Milton, river flows over rapids for several miles; also after leaving East Rochester. No buildings or houses along the river banks except at these points.

The chemical determinations of the Salmon Falls water, in parts per 100,000, were as follows: Transparency, clear; color, 0.3; odor, slightly earthy; chlorine, 0.06; albuminoid ammonia, 0.0174; free ammonia, 0.0072; nitrates, 0.014; total residue, 8.40, of which 1.60 was fixed and 6.80 volatile, there being considerable blackening on ignition. This sample was pronounced by Dr. Wood as the best of samples submitted from three sources, so far as he could judge "without knowing anything about their surroundings or history," which information he requested. On receiving this Dr. Wood wrote as follows:

> The objection to the Salmon Falls River is the existence of the towns above. If, however, the thickly settled parts of the towns are not on the banks of the river, there is probably little danger from their drainage at present.
>
> That is, however, a question for you to decide rather than for me. Certainly, the Salmon Falls River water as it flows in the stream is the best of the three, and if the danger of sewage pollution from the towns above is practically absent, I should recommend its water rather than Nos. 1 and 2.

Mr. Wheeler believed that the limited size of the two communities named, their remoteness from Somersworth and the understanding that they had no sewerage system practically precluded immediate danger from sewage pollution. In case such danger should arise in the future he stated that appeals could be made to the legislature or the courts for protection, or the water might be filtered. The city at once requested information regarding filtration, and eventually it was decided to put in slow sand filters. Bids for such a plant were received on Sept. 22, 1896, the prices, based on the estimated quantities, ranging from $22,037 to $36,303. The contract was awarded to the lowest bidder, Ames & O'Shea, of Somersworth, at the price named. The contractors threw up the contract when about one-third of the work, in value, had been completed. The contract for completing the plant was awarded to the Great Falls Granite Co. (Spence & Coombs). The original contract price of $22,037 did not include certain accessories necessary to the operation of the plant. The engineers' estimate for the beds and all these accessories was $29,892, and the work actually cost $32,720, minus an amount to be recovered upon the bond of the first contractors, Ames & O'Shea. This amount is made up of sums paid the second contractor that were chargeable to the first.

The filter bed is located between the river and the pumping station, only a short distance from each. Its design is shown by the accompanying plan and sections. Water flows from the river to



Section C–D–E–F–G–H.

PLAN AND SECTIONS OF COVERED FILTER BED AT SOMERSWORTH, N. H.
Wm. Wheeler, M. Am. Soc. C. E., Engineer.

the filter bed, and from it to the pump well, by gravity. There is a screen chamber at the river and a regulating chamber at the other end of the bed. The filter is in one compartment, as shown by the plan, but water is admitted to it over two 12-ft. weirs, which, with the regulating chamber, are described by Mr. Wheeler in his report to the Committee on Water Supply, as follows:

> The raw water enters the filter through a conduit leading from the screen well to a point opposite the middle of the northeasterly side. It is of 15-in. vitrified pipe and is divided at the point just indicated into two lines, each of 12-in. pipe, which enter through openings in the wall of the filter at grade 95.50 (center of bore), each 10.50 ft. from, and upon opposite sides of, the central line of the lintel piers above described. At each influent point a horizontal pocket or chamber is formed in the face of the wall, 12 ft. long, 25 ins. high, and 12 ins. deep. Covering the lower part of each of these influent pockets or chambers is a removable flashboard or sand-stop, resting in angle iron fastenings, its upper edge being at or slightly above the level of the top of the sand bed, over which the water enters the filter in two streams, each having a width of 12 ft., thus obviating any objectionable disturbance of the surface of the sand bed.
>
> The regulating chamber is about 13 ft. long and 10 ft. wide. It is divided by a brick partition into two compartments, one receiving the clear water from the filter through the main collecting pipe, and containing the apparatus for regulating the rate of filtration so as to maintain uniformity therein, the other an effluent compartment connecting directly with the main conduit leading from screen well to pump well. The enclosing walls and partitions are of brick, laid in Portland cement mortar upon foundations of Portland cement concrete, which form also the floors of the two compartments, that of the first being at grade 89.50 and that of the effluent compartment at grade 92.00.
>
> The connections between the filter and first compartment, between the two compartments, and between the effluent compartment and the conduit to pump well, are made in each case through 16-in. flanged pipe castings, built into the walls and fitted with Eddy gate-valves, the stems of which extend up through the floor of the room above, to be operated by hand wheels suitably mounted on gate stands.

The ordinary level of the river at the intake is about grade 100.

The filter bed has a total depth of 5 ft., there being 1 ft. of selected gravel at the bottom, overlaid by 4 ft. of sand fairly uniform in size, and with 10% of its total, by weight, composed of grains of from 0.30 to 0.45 mm. (0.012 to 0.015 ins.) in diameter. The dimensions of the underdrains are shown on the plan. They are laid with their bottoms at such a grade as will bring the tops of the pipes of different sizes all to the same level, and thus give the same depth of filtering material above them. The net area of the filtering material is 21,780 sq. ft., or practically one-half acre. The combined area of the 49 piers is 444 sq. ft. The middle row of piers is larger than the others, since it has to support a railway siding. This siding is available for handling filtering material when the bed is being cleaned or renewed. Besides supporting the railway siding the heavy piers were designed to withstand the thrust from the covering of one-half the beds. The contract required at least one-half the centers for the covering arches, or all those on one side of the center line, to be placed complete and not removed or struck until the roof on that side was finished.

The material at the bottom of the excavation for the filter bed was of gravel and ledge, at an elevation about 8½ ft. below the ordinary level of the river. The filtering material rests on this surface. The outer walls of the filter bed are laid in American Rosendale cement, but Portland cement was used for all the rest of the stone and brick masonry, and for the concrete.

When it is desired to clean the filter bed the water can be drawn down to about the level of its upper surface by the regular pumps, then completely drawn out by a centrifugal pump, built by the Lawrence Machine Co., located in the house which covers the regulating chamber. After the filter had been in operation about three months, the water was pumped out. It was found that the top of the sand, only, was discolored, and that but slightly. No cleaning was done then, nor had any been done up to Sept. 16, when a member of the editorial staff of this journal visited the plant. No analyses of the filtered water have been made.

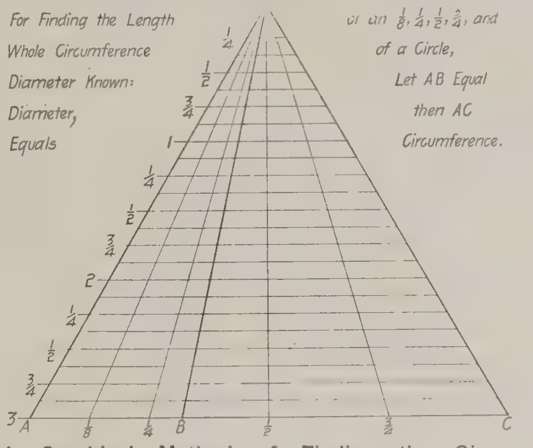
Two 1,500,000-gallon pumps lift the water to a stand-pipe about 40 × 95 ft. The storage afforded by this structure is thought to be sufficient to allow the shutting down of the filter bed for cleaning.

We are indebted to Mr. Wheeler for the drawings and some of the other matter used in the preparation of this article, and to the local officials in charge of the water-works for information given when our representative visited the plant.

A UNIVERSAL CIRCULAR SCALE.

In our issue of March 30, 1893, was published a universal scale for dividing a line of unknown length into any number of equal parts, or for dividing a line of known or unknown length proportionally to another line of known or unknown length. The scale here illustrated is based upon a similar principle, and has for its purpose the finding of the length of the circumference of any circle, or the length of an arc equal to an eighth, quarter, half or three-quarters of the total arc, when the diameter is known.

This scale takes the form of an equilateral triangle, of which the base, A C, is equal to the circumference of a circle whose diameter is the distance A B. The other radial lines shown cut the base, A C, at points equal to ⅛, ¼, ½ or any desired division of the length of the total arc, or circumference. The lines drawn parallel to the base serve two purposes: those with figures attached give a graphic table of circumferences for circles whose diameters are 1, 1¼, 1½-in., etc. In the second place, these lines serve as a guide to the eye in using the scale.



A Graphical Method of Finding the Circumference of a Circle or Any Fraction Thereof, the Diameter being Known.

In using this scale mark off on the edge of a strip of paper the length of the diameter as taken from the object or drawing. Fit this distance between the radial lines, A and B, always keeping the edge of the strip parallel to one of the horizontal lines; then mark on the strip the point where the radial line, C, strikes it, and the distance between the marks, A and C, measured by the same scale as the diameter, will be the length of the circumference. Points taken on the other radial lines will, in a similar manner, give the length of arc for the ⅛, ¼, ½ and ¾ of the total circumference, or for any other division of the circumference as originally laid out on the base, A C.

The designer of this universal scale and the one previously referred to, is Mr. J. Ernest G. Yalden, Superintendent of the Baron de Hirsch Trade Schools, of New York, and he regards it as the most accurate and least complicated of the many geometrical constructions proposed for determining the length of the circumference, or divisions of this arc. It can be made of any size, and with any fractional part desired; and will prove useful to draftsmen, and especially to sheet-metal workers. For general trade purposes it is to be preferred to calculation where dimensions are given in inches, as it is difficult to use the fractional parts of an inch.

TESTS OF FORMALDEHYDE AS A DISINFECTANT AT NEWTON, MASS.

The report of the Massachusetts State Board of Health for 1897 contains an interesting review of some formaldehyde tests at Newton, Mass. The review was contributed by the Board of Health of Newton, and is as follows:

> During July and August, through the kindness of Prof. S. Burrage, of Purdue University, Lafayette, Ind., the board was enabled to make some interesting and valuable experiments at the Newton Hospital as to the value of formaldehyde as a germicide. The tests extended over a period of about six weeks, and the results have been made the subject of a paper by Professor Burrage, which is too long to be included in this report, but a short resume of the subject will be of interest.
>
> The original intention was to determine what form of formaldehyde generator was the most efficient and best adapted for use by the average unskilled operator. Four different styles of generators were used in the tests, two producing the gas from the 40% solution, and two testing it directly from wood alcohol.
>
> The results taken as a whole showed that formaldehyde is not as fatal to disease germs as is generally claimed, at least when the exposure is for so short a period as six hours.
>
> There was no great difference in the efficiency of the different forms of generator, the results being practically the same with each. A number of tests were made with each generator, in order to have as large an amount of information as possible upon which to base conclusions.
>
> No record was kept of the amount of gas evolved by each generator, although the same amount of solution (about one quart) was used in each of the first form, and about one liter of alcohol was consumed by each of the second form. This would give, approximately, 16 ozs. of formalin and 500 cu. cm. of alcohol to 1,000 cu. ft.
>
> The practical conclusion to be drawn from these tests is that, while formaldehyde remains the most practical gaseous disinfectant which we possess, a number of elements must be taken into account in order to obtain satisfactory results. The length of time of the exposure, the amount of gas used per 1,000 cu. ft., and the care with which crevices are closed to prevent the diffusion of gas, are all of importance and must be taken into consideration.
>
> After the tests with formaldehyde had been finished, dry sulphur fumes were used under the same conditions, with the result that it was shown that they had absolutely no effect upon the test cultures, those which were exposed to its action growing as rapidly and luxuriantly as the controls.
>
> While the city is well equipped for house and room disinfection by the use of formaldehyde, it is still without the proper method of sterilizing the more bulky of household furniture, such as carpets, mattresses, etc., into the substance of which the formaldehyde does not penetrate. For this purpose a steam disinfecting plant is needed, and it is with great satisfaction that the board is able to report that such a plant will be erected in the near future, in connection with the proposed new heating and power plant for the municipal buildings. The sterilizing chamber will be of the most approved construction, and large enough to take the most bulky articles, being 7 × 5 ft.

Reports from other local boards of health in Massachusetts show that at least 14 boards adopted formaldehyde in 1897.

◆

THE NEW YORK RAPID TRANSIT COMMISSION, at its last meeting considered the situation created by the inability of the enlarged city of Manhattan to borrow the sum required to build the road in the manner planned. The two courses open, says President Orr in his statement on behalf of the Commission, are these: Request legislation making the rapid transit road an exclusive asset of the County of New York, or the boroughs of Manhattan and the Bronx, and charge the debt exclusively to this county; or, request legislation enabling the Board to sell a charter for the road to private capitalists. The statement issued explains how either of these alternative propositions may be provided for in one legislative act, and enters into a discussion of the county charge and gives legal opinions on the proposed action.

◆

MUNICIPAL OWNERSHIP OF WATER-WORKS at Indianapolis has been under discussion for some time past, but now seems likely to be postponed for a number of years unless the Indianapolis Water Co. will make the city a more favorable offer than the one recently submitted. The city is unable to issue bonds to pay for the works, so the company proposed to transfer its stock to the city for $200,000 cash, and an agreement to pay the company $120,000 a year for 25 years, the stock, however, to be subject to a mortgage indebtedness of $3,350,000, of which $2,850,000 bears 6% and $500,000 bears 5% interest. To cancel the debt, the water company would pay off $75,000 a year for five years, and increase the amount annually thereafter by the amount of reduction in the interest charges. It was calculated that at the end of the 25 years the bonds would all be paid. Mr. John W. Hill, M. Am. Soc. C. E., of Cincinnati, was engaged to report on the physical condition and the value of the water plant. The cost of duplication at present prices Mr. Hill placed at $1,950,000, from which he deducted $270,000 for depreciation, leaving $1,680,000 as the present value of the works, on this basis. This allows nothing for the franchise. He also presented figures regarding the value of the plant as determined by its earning power, which, with the other parts of his report and the company's proposition to sell the plant to the city, have all been printed in pamphlet form and can doubtless be obtained from Mr. Hill by those interested. The city authorities, having declined to accept the proposition, basing their decision largely on Mr. Hill's report, from which they conclude the price to be paid is excessive.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; *6 months,* $2 50; *2 months,* $1.00. *To all other countries in the Postal Union: Regular Edition, One Year,* $7 60 (31 *shillings*); *Thin Paper Edition, One Year,* $6.31 (26 *shillings*). *SINGLE COPIES of any number in current year,* 15 *cents.*

In ordering changes of mailing addresses, state BOTH old and new addresses; notice of change should reach us by Tuesday to be effective for the issue of the current week. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 *means that subscription is paid to the 32d week (that is the issue of Aug.* 11) *of the year* 1898; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want noticees, special rates, see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

The invitation of the Quebec Bridge Co. for designs and bids for the construction of a bridge across the St. Lawrence River, near Quebec, was discussed by a correspondent in our last issue, who suggested that before bridge companies expend any considerable sum upon designs and estimates in response to this invitation, they would do well to investigate the financial status of the company and the prospects that it will be able to secure the funds to carry out its enterprise. The subject is again taken up in our present issue by another correspondent, who tells the story of how another Canadian bridge company, which also proposed to bridge the St. Lawrence, offered prizes for the best designs for its structure, and after the prizes were awarded failed to pay them.

As most of our readers know, architects, who meet much more frequently than engineers the calls for the submission of designs in a competition, are generally opposed to competitions, and approve them only when they are conducted under a stringent code of rules laid down by the Architectural Societies. It would be well, it seems to us, if Engineering Societies would follow this example and formulate rules to govern competitions for engineering work. Among the first of such rules, judging by past experience, should be the requirement that the amount of the prizes should be paid over to the expert commission which is to decide upon the relative merit of the plans (this payment to be made at the time when the call for plans is announced), and should be by it paid over to the successful competitors, coincident with the announcement of their names. Such a rule would not only cover the case of the financial inability of the party ordering the competition to pay the prizes after their announcement, but would also prevent such an overruling of the experts' decision as occurred a short time ago in the competition for the Pennsylvania State Capitol.

◆

The average architect or engineer knows little or nothing as to the financial responsibility of any concern asking for competitive plans; and manifestly cannot afford to spend much to find it out. He judges of the competition, in most cases, by the character of the experts who are to pass on the plans. In the case of the Montreal Bridge Company, for instance, we presume that many engineers relied on their use of the name of Mr. Walter Shanly as their consulting engineer, as evidence that a fair award would be made, and that the company had at least a moderate financial standing. But, while Mr. Shanly appears to have had a free hand in the award of the prizes, he had neither the authority nor the power "to draw blood from a turnip," and thus it happens that the prizes remain unpaid to this day.

It may be interesting in this connection to explain something of the financial status of such Canadian engineering enterprises as the two which we have been discussing. By a long-established precedent Canada is committed to the policy of subsidizing public works of various kinds, and this is now so well understood that in the London money market, where nearly all Canadian enterprises are financed, it is well-nigh impossible to secure funds for any such work as these St. Lawrence bridges unless the promoters can show something in the way of a Government grant in aid of the project. On the other hand, if a fair-sized subsidy is once secured, it is easy enough to get funds to cover the remaining cost. The mountain load of public debts which Canada has piled up, however, is getting so serious a matter that the way of the subsidy-seeker has become a hard one. It is, in fact, we believe, only a question of time when public opinion will become so strong that the whole corruption-breeding system of subsidies to public works will be abolished, and the country will get down to the safe and sound basis of letting private capital undertake such enterprises as promise a fair return on the money invested.

Meanwhile, engineers and manufacturing concerns engaged in engineering work will do well to inquire closely into the financial standing of Canadian enterprises before expending any considerable amount of either time or money upon their work.

◆

The severe snowstorm which swept over the Eastern States on Nov. 26 gave a crucial trial to the conduit electric street railway lines in New York city.

The various lines were tied up from ten to fifteen hours by the storm. The main cause of the blockade was the depth of snow on the tracks. In this respect the conduit system was no more interfered with, of course, than any other surface railway system would have been, except perhaps the cable. The secret in keeping a street railway or a steam railway open during severe snowstorms is first to keep the tracks clear by running snowplows frequently enough to prevent the accumulation of drifts; second, run no more cars than the motive power can haul. The difficulty which a street railway manager finds in putting these rules in practice is that when he cuts down the number of his cars, those that remain are overloaded, and the traveling public bitterly complains because the cars run at longer intervals than usual just when they are most in demand.

Besides the difficulties with the snow obstructing the track, however, the movement of cars on the electric conduit roads was more or less interfered with by some other troubles of a more novel character, resulting from the accumulation of snow in the conduit. Of course, in any driving storm, more or less snow sifts in through the slot, and when a car runs along, a suction is created behind the plow that draws down a shower of snow from the cloud stirred up by the wheels. Past experience with this type of road, both in Washington and New York, has pretty definitely established the fact that water or slush, if allowed to accumulate in the conduit in sufficient amounts, will short-circuit the conductors, throw the station circuit-breakers, and thus interrupt the current supply to the flooded section. That snow would do the same thing would hardly be expected with the comparatively low voltages used, since snow is practically distilled water, and when dry is made up of a mass of ice crystals with air spaces interspersed.

Experience in the recent storm, however, showed that short circuits did occur at several places on the line, and in several instances they were accompanied by a pyrotechnic display of flames shooting from the slot in sufficient volume to cause considerable alarm to passengers and to excite a large amount of speculation as to their cause. From the best information we have been able to obtain, it appears that the chief cause of the short-circuiting was the salting of the tracks for the purpose of melting the snow—a relic of practice in the old horse-car days. The snow alone in the conduit, it is stated, had not enough conductivity to set up an arc; but when the salt slush dripped down upon it, its conductivity was increased enough to start an arc. The salt solution also short circuited the plows and caused arcing, which sometimes ran along the conducting rails for some distance before it was broken.

In some previous storms, the conduit lines have had some trouble with the collection of ice on the conducting rails in the conduit. In the present storm, however, the atmospheric conditions were such that this did not occur.

An amusing incident in connection with the recent storm was an interview with President Vreeland, of the Metropolitan Traction Co., published in one of the daily papers, in which that officer was made to say that the cause of the stoppage of the cars was the formation of ice on the rails, preventing the flow of current from the wheels to the rail. It is, of course, not to be supposed that Mr. Vreeland is ignorant of the fact that in the conduit system, both positive and negative conductors are in the conduit and no current flows from the car wheels to the rail. The error was doubtless due to the reporter's misunderstanding. A discriminating electrical journal of this city, however, picked up this interview, swallowed it whole, and proceeded to preach a sermon to the Metropolitan Street Ry. Co. on the folly of spending so much money on its conduit systems and failing to provide "a complete metallic circuit without regard to the rails."

◆

COMMERCIAL EDUCATION IN THE UNITED STATES.

The rapid growth in American exports of manufactured goods during the past four years has made plainly evident the need of specially-trained men to conduct our export business in foreign countries, and especially in those regions of Asia, Africa and South America, for whose trade all civilized nations are in keen competition. It is true that we are rapidly increasing our exports of manufactured goods in many lines; but we are doing it largely by virtue of superior facilities for production, which enable us to undersell our rivals. When it is a question of working up new trade, however, or meeting our competitors upon even terms as regards price and quality, it is generally admitted that our salesmen in foreign countries cannot compare with the Germans in point of efficiency. Germany has led all other nations in the establishment of schools designed especially to train those who are to follow commercial life.

In the United States, it was not until 1881 that any of our institutions of learning recognized the need of any such special training. In that year the University of Pennsylvania opened a department known as the Wharton School of Finance and Economy, with a four-year course and a curriculum embracing public law and politics in this and other countries; mercantile law and practice, including accounting; history economics and social science, including banking and currency and the revenue systems of governments, etc. The University of Chicago and the University of California also have separate departments of this sort recently established; while Harvard, Yale, Columbia and a number of other prominent universities offer special courses to students which cover this field.

For a higher education in this direction these schools are doubtless doing good work; but they aim too high for the average young business man,

and do not reach the same number or class of individuals as are served by somewhat similar European institutions. The phenomenal trade expansion of Germany is the direct outcome of her system of technical education. She has sent out men carefully trained to study the resources and wants of other nations; and by thoroughly-equipped technical and commercial schools, she has fitted those who carry on her manufactures and commerce how best to supply these wants. The advantages possessed by a graduate of one of the German commercial schools are very evident when we consider that he is required to conduct an "office correspondence" in German, French and English, and must be able to converse in one other language, either Spanish, Italian or Dutch; he must be familiar with the geography of foreign countries, their history and commercial conditions and customs; and at the school well-filled museums make him familiar with the animal, vegetable and mineral products of other lands. When such a man goes abroad to take a place in the foreign house of a German exporter, he is able to almost at once begin the work of forming acquaintance and business connections, whereas the average graduate of an American high school or college, having at best only a smattering of any other language than his own, and ignorant of the machinery of commerce, finds that he has everything to learn, and that learning under such circumstances is a very difficult task.

That a knowledge of the conditions to be met in foreign markets is of value to those at home as well as those abroad, is shown in the November issue of "Consular Reports." In that issue we find four American consuls criticising American trade methods, due purely to ignorance or to disregard of the directions of foreign importers. The chief complaint is that of bad packing, and the non-observance of foreign customs law. Few of our shippers seem to know that in some countries duties are levied on the gross weight and determined upon the highest-priced article within the package; and a single gold watch packed in a box of cheap cotton prints would result in the computation of the duty as if the case contained only gold watches. The bad condition of American cotton bales, received at Liverpool, occasioned a loss of $500,000 to exporters last season. The Egyptian and East Indian cotton bales are much more compressed, have a stronger and better covering than those coming from the United States, and always arrive in almost perfect condition. A failure to observe the explicit directions of importers, as to dimensions and methods of packing, or to consider the customs and superstitions of possible consumers also stand in our way, and damage the sale of otherwise excellent goods. In China, a fanciful Chinese dragon, as a trademark, will sell goods better than if the housemark were used; in Russia, German makers took away from English firms a considerable trade in handkerchiefs for the head, simply by making them of the peculiar dimensions which the people preferred. Peculiar patterns and colors of calico prints, to suit the fancies of special races, and special forms of tools for farmers or artisans are often necessary to secure the trade of a particular section.

In other words, if we propose to extend our commerce, there is very much to be learned.

Some American manufacturers have already been shrewd enough to appreciate these facts. In Nicaragua, we are told that practically all the machetes used are made by Collins, of Hartford, Conn., who has produced a blade of exactly the shape the natives desire, and as a consequence they will not buy a machete unless "Collins" is stamped on the blade.

It thus appears that if we are to compete for the world's trade in all lines, and not merely those in which our wealth of natural resources gives us a large advantage, there is much to be learned both by our manufacturers at home and by their agents sent abroad. To obtain this knowledge we must make a beginning, at least, in what may be called popular commercial education. The models exist in European institutions of a similar character, though these would doubtless have to be modified to suit our conditions. In this connection, it is an encouraging indication of the appreciation of the need of such training to note that a committee of the New York Chamber of Commerce was recently appointed to prepare and submit a plan for the establishment and development of better commercial education in our secondary and higher schools. England has been forced to similar action, because German and other foreign clerks, on account of their superior commercial training and ability, were rapidly supplanting young Englishmen in positions of trust. The London Chamber of Commerce now grants commercial certificates to candidates who produce evidence of proficiency, according to certain prescribed branches of study, including, at least, two languages, and elementary drawing, chemistry and physics. The Paris Chamber of Commerce manages the Paris Commercial High School; and exemption from military service, for more than one year, is an inducement held out to attend this school. The action of the New York Chamber of Commerce is timely, and it is to be hoped that good results will follow its recommendations.

LETTERS TO THE EDITOR.

Canadian Bridge Schemes and Ethics for Engineers.

Sir: In your issue of Dec. 1, 1898, in answer to the article by "A. P. B.," on "An Opportunity for Bridge Engineers to Practice Engineering Ethics," Mr. Barthe affects a great deal of righteous indignation because "the Quebec Bridge Co. is so sorely arraigned before the tribunal of public opinion" on the general charge of "deliberate attempt to get something for nothing," and because of the "imputation that this company, composed as it is of 200 of the best citizens of Quebec, is unable to pay a few thousand dollars for the technical information it requires," etc.

A. P. B.'s stand is well taken, though one course that he mentions—that of offering prizes for the best plan—has its disadvantages.

In this connection, attention is called to another Canadian case of "gall unparalleled" in which the attempt to get something for nothing was successful.

In the spring of 1895 the Montreal Bridge Co. called for competitive plans for a proposed bridge across the St. Lawrence, and offered prizes for the first and second best plans, of $1,000 and $500, respectively. A large number of plans were submitted and the awards were made; but neither of these prizes has ever been paid.

In view of this fact, engineers are justified in questioning the methods and intentions of the Quebec Bridge Co.—even if it is composed of "200 of the best citizens of Quebec." Yours very truly,

A. L. Bowman.

71 Broadway, New York city, Dec. 3, 1898.

(We have commented on this letter in our editorial columns.—Ed.)

A Battle of Quotations.

Sir: Some time ago those of the trunk line railways which have long been allowed to charge a differential fare to Western points under the agreement were surprised to learn that the "standard" lines had put into effect lower rates from Buffalo to the Pacific Coast, and had requested Western connections to so arrange their rates as to make them the same as the rates enjoyed by the differential lines. The steps were taken somewhat secretly, and the differential lines did not learn of the change until some time after the circulars had been sent out. A meeting was held in New York last week by the differential lines to discuss the matter. David B. Martin, Manager Passenger Traffic of the Baltimore & Ohio R. R., was chosen chairman, and Charles S. Lee, of the Lehigh Valley, acted as secretary. After some discussion, the following telegram was sent to Geo. H. Daniels, of the New York Central; A. J. Smith, of the Lake Shore; O. W. Ruggles, of the Michigan Central; J. R. Wood, of the Pennsylvania; E. A. Ford, of the Pan Handle, and E. O. McCormick, of the Big Four:

> We learn with regret that at this most inopportune time, without conference or advice, you have arbitrarily reduced regularly established fares from common points in our territory to Pacific Coast points, and by request upon initial lines at the Pacific Coast, succeeded in obtaining similar reductions in authorized fares eastbound. We deprecate such arbitrary action as tending to demoralization, and calculated to provoke retaliatory measures and unnecessarily reduce the revenues of all lines. We therefore, respectfully enter this, our protest, against such unwarranted action on your part, suggesting that in our opinion, when changes in authorized fares are contemplated, due notice should be given to all interested lines, in accordance with the established usage, and would request immediate restoration of rates to those in effect Nov. 1, 1898, and ask your prompt reply, to be addressed to D. B. Martin, Baltimore, Md.

One of the first replies was received from George H. Daniels, of the New York Central, and read as follows:

> D. B. Martin, Baltimore, Md.:
>
> I think it would be an opportune time for you to read the 41st verse of the 6th chapter of the Gospel according to St. Luke.

Mr. Martin, after some difficulty, found the verse, which reads as follows:

> And why beholdest thou the mote that is in thy brother's eye, but perceivest not the beam that is in thine own eye.

Mr. Martin undertook a little Biblical research on his own hook, and wired Mr. Daniels as follows:

> Answering yours of Dec. 2, we have been guided through life by the teachings of St. Luke, and fully concur that his sixth chapter is very appropriate to the case in point, and for your personal application would advise reading last half of verse immediately following.—D. B. Martin.

The last half of the following verse reads as follows:

> Thou hypocrite, cast out first the beam out of thine own eye, and then shalt thou see clearly to pull out the mote that is in thy brother's eye.

Yours truly, J. F. M.

Baltimore, Md., Dec. 5, 1898.

(We can add to our correspondent's story that Mr. Daniels has now taken up the study of Shakespeare, and was about to refer his adversary to a certain passage in "The Merchant of Venice," Act I., Scene 3.† The reflection that it might be used as a two-edged sword, however, caused him to refrain.—Ed.)

The "Board of Awards" at Baltimore and Other Features of the New City Charter.

Sir: In your issue of Nov. 24 you comment on that part of the new charter of Baltimore which provides for the letting of contracts for work done and material furnished the city, by a Board of Awards, certain city officials, ex-officio, composing the board. You call attention to the defect in the provision which requires the award to be made to the "lowest responsible bidder," in that the lowest bid may be too high, etc., and which, in the absence of this requirement, would warrant the board in rejecting all bids. This requirement that the lowest responsible bidder shall always be awarded the contract has been defended by saying that it prevents crookedness between the board or some of its members and an irresponsible or dishonest bidder.

An answer to this would be that in a board of city officials whose standing in integrity is that of a Mayor, Comptroller, City Register, City Solicitor and the President of one branch of the city council, the chances of collusion with a dishonest contractor, while possible, are rather remote.

Another defect (though not a serious one) is the requirement that the successful bidder shall give bond in double the amount of the contract price. This is excessive and entirely unnecessary in protecting the city's interests. Contractors in making up their estimates for work or material advertised for will not fail to add the premium on this bond to their proposal, and for this the city will have to pay. Take for example the paving of a street estimated at a cost of $50,000. This, of course, means a $100,000 bond. Moreover, if the contractor were sued on his bond, for failure to comply with specifications or complete the contract, the court would very likely award the city only damages equal in amount to the loss sustained, which in hardly any case could exceed the amount of the contract, and in many cases would be but nominal. Previous to the adoption of the new charter it had been the custom in the City Commissioners Department to fix the bond at about one-third the amount of the contract. This proportion was increased in special cases, such as the erection of a bridge or in emergency work.

Shortly after the new charter went into effect the City Commissioners Department solicited, among other material for constructing a sewer, bids for about 200 barrels af natural cement. The specifications contained the usual provisions for tensile tests (for 1, 7 and 28 days). Two of the brands of cement (offered by different bidders) differed in price by about 4 cts. per bbl. Both kinds satisfied the specifications, but the higher priced was much the better and considerably exceeded the requirements of the specifications, as shown by tests made in the Department. The board had no discretion in the matter but to award the contract to the party offering the lower priced material. The difference in the cost on the estimated amount was about $8, whereas the better quality of the higher priced cement, as shown by the tests, would probably have allowed a lower proportion in the mortar and thereby made it the cheaper in the end.

It is simply one of those cases where it is difficult to draw the line guarding the interest of the taxpayer without encroaching on ordinary business principles. A most excellent provision in the new charter is that all appropriations for public improvements exceeding $2,000 shall, before being passed by the City Council, be referred to the Board of Public Improvements and to the Board of Estimates, in case it has not already been included in the Board of Estimates' budget for that year. The first-named board passes on the value of the measure as a public improvement, and the Board of Estimates passes on the probable cost and availability of the funds to pay for it.

---

†"The Devil can cite Scripture for his purpose."

The council will hereafter be unable to appropriate money not provided for and included in the Board of Estimates' annual report for the year. By this means the "floating debt" will be avoided, which has heretofore been the "bete noir" of the party in power and has been the subject of some extravagant oratory and literature in political campaigns.

James A. Paige.

Baltimore, Nov. 28, 1898.

The New Printing Plant of the W. B. Conkey Co.

Sir: In Engineering News, of Nov. 17, we notice the article and the editorial regarding our new establishment.

Regarding the editorial, the gentleman who wrote it evidently did not grasp the plan of our building. I have asked our architect, Mr. Geo. C. Nimmons, to take up the matter and write you concerning it, as the great feature of our plant is its fireproof construction, the absolute impossibility of burning and the ease of exit for employees in case of fire, there being large windows only 2½ ft. from the ground. The entire structure is fireproof, including the roof, which is of heavy galvanized iron, the supports being iron columns, and every partition of fireproof tile 4 to 6 ins. thick. The floor is laid upon cinders solidly packed against the wood, which is 2-in. Norway pine, and 1-in. tongued and grooved maple floor on top. There are also 2-in. fire hose connections to every 100 ft. of floor space, with 50 ft. of hose attached, throughout the building, and our rate of insurance is only 0.5%. In Chicago we carried an insurance of $450,000 on stock and machinery, and in Hammond we carry only $25,000 on machinery and $100,000 on stock.

We recently had a call from the President of the Society of Engineers of London, England, together with such gentlemen as the business manager of the Curtis Publishing Co., New York city; Mr. Talheimer, general manager of the American Book Co.; Mr. A. G. Spaulding, and many representatives of large manufacturing concerns, who have been more than astonished and pleased with the wonderful results that have been attained by this new construction scheme for manufacturing plants.

I mention the three gentlemen above, because they are immediately going to construct new plants, and will adopt our plan, which is thought quite the most perfect scheme for a manufacturing plant that has ever been conceived. There is no question but that the erection of our plant has demonstrated a new condition which will mark a new era in manufacturing plants. Believe me,

Very truly yours,
W. B. Conkey Co.,
W. B. Conkey, Pres.

Hammond, Ind., Nov. 23, 1898.

Sir: I am much pleased to note from the article in your issue of Nov. 17 that you have been interested in the new methods of construction adopted for the plant of the W. B. Conkey Co., at Hammond, Ind., of which I was the architect. As, in your editorial discussion of the subject, you have raised the point as to its fireproof qualities, etc., and as a number of other large manufacturers are about to adopt this style of building, a further description of this plant will, I trust, be of interest to you and also to the readers of your valued publication.

The plant consists of a main factory building one story high, covering about four acres of ground, and is nearly square in plan. It has no interior light courts or areas, as the light all comes from the roof, and the floor and roof are therefore continuous over the entire space of four acres. The office building, with its various apartments, and the employees' entrances, dining rooms, bicycle rooms, toilet rooms, hospital, etc, for the employees, adjoin the main factory and extend clear across the east side, which is the front, and which faces on a park of five acres, landscaped especially for the recreation and enjoyment of the factory hands, having a lake, walks, drives, flower gardens, etc.

Adjoining the north side of the main factory building is the building for the generating plant, which was described in your previous issue.

The roof of the main factory building is perhaps the most striking feature of the construction. The idea for this was borrowed from Europe, principally from the National Fire Arms Works, of Belgium, and an immense bicycle factory in Paris. Both of these works are built on this scheme of obtaining north light only, through a series of windows arranged in parallel rows over the entire roof, thereby admitting only the north white light and no sunlight, but in such quantities as to flood the building with pure white light, over every square foot of floor surface.

The first objection that is likely to occur in reference to this kind of roof, is the possibility of snow collecting in the valleys between the skylights. This is guarded against in a manner similar to that employed for hot-houses, by keeping the bottom of the gutter and the glass heated so as to melt the snow as it falls. This condition produces another difficulty, greater than all to care for, and that is the condensation on the under side of the glass, etc. In order to care for this, a complete system of condensation gutters has been made which collects all the condensation and conducts it to the outside of the building.

The heating and ventilating of the building is accomplished by a blast system, with the heating ducts under the floor, which supply registers throughout the plant, arranged on the side walls of each department. The placing of the heating ducts under the floor does away with the objectionable large galvanized iron ducts usually placed on the ceiling. The heating system can be made to produce a mild heat for the seasons of spring and fall, and can also be turned into a cooling system for summer; by running cold water through the steam pipes at the fans and changing the air every 15 minutes with cool air in hot weather.

The fireproof qualities of the building were among the principal features considered, and it was constructed in accordance with the advice and suggestions of the fire underwriters, who have placed a very low rate of insurance on the building. The building is practically fireproof from the nature of its construction. Fire cannot get under the floor nor through the walls dividing the different departments, as the walls are made of heavy tile; the iron columns in the wall are fireproof, and the openings are closed with iron fire doors. The office department has a thick brick fire wall dividing it off entirely. The floor is built of heavy plank and finished maple laid on sleepers which are bedded in cinders rolled with a six-ton roller, which leaves no space under the floor for fire or vermin, and incidentally permits the floor to be loaded almost indefinitely. Under these conditions, fire cannot get under the building, nor through the partitions, nor spread any further than the department in which it starts. As an additional safeguard, hose pipes with reels have been placed so as to cover every part of the building with water in case of a fire. It is also true that panics among the employees in the time of fire would not be likely to occur.

The advantages to be gained by this kind of a building in a general way over the ordinary ones of two or more stories, or of a plant that consists of a number of one-story isolated buildings, are, first of all, that it brings the different departments into closest contact and saves much time and expense in handling the product and in superintending the men and work, as it is all under one roof and on one floor, with no elevators or stairs, and all concentrated within the smallest possible area. A building, therefore, arranged with all its departments as nearly a square as possible, with the raw material traveling in the smallest possible circle, is the most economical arrangement, both as to handling goods and as to cost of buildings. A building, square in plan, with say 32,000 sq. ft. of floor area, costs just half as much to enclose with a brick wall as two buildings of the same area each 40 ft. wide by 400 ft. long, a width not uncommon in factory plants.

The roof of the square building would cost more than the others, on account of the extra glass, but the saving in the outside wall would more than make up for this extra expense. In a two or more storied plant the saving of the heavy floor supports by the one-story square building is also great enough to make up for the greater cost of a glass roof. It is also true that a building of the type used for the Conkey plant, with the perfect north light, is cheaper to build than either the one-story building with the old lantern-shaped roof, or the mill constructed building of two or more stories.

Factory buildings of this country, as a rule, have received comparatively little study by architects, and are very often defective as to their arrangement and light. As competition at home and with foreign countries becomes closer among manufacturers, it is evident that the problem of planning factory buildings grows in importance, as a great deal can be done by the architect in planning the buildings so as to reduce the cost of producing goods.

George C. Nimmons,
Architect.

94 La Salle St., Chicago, Nov. 28, 1898.

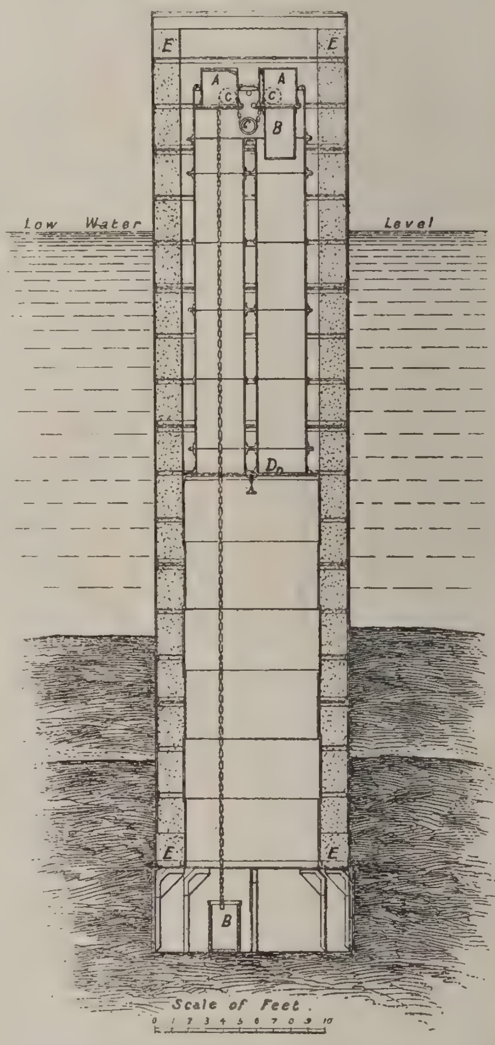
(We give space with pleasure to the above communications; but are obliged to confess ourselves still unconvinced as to the wisdom, from the standpoint of fire protection, of putting such a great area of buildings under what is practically a single roof. We freely admit that the division of the building by solid fireproof partitions is calculated to lessen materially the risk, but we do not see that it is equivalent to the distribution of the risk into separate buildings, far enough apart to permit the firemen to work between.

It must always be remembered, of course, in the study of questions of fire protection, that although a building itself may be incombustible, its contents generally afford material enough to feed a brisk fire, especially in any manufacturing plant where the floors gradually become more or less saturated with oil. Admitting, then, that fire is always liable to occur, the question is how its spread may be checked. The weak point in the Conkey establishment, it seems to us, is that all the work in fighting fire must be done on the inside. The fire resisting partitions, if the openings in them are closed by good fire doors, may do their work, but if one department gets ablaze, will not the flames burst through the glass of the roof, and in case of high wind, be carried into other departments through the breaking of other skylights by the heat? As we write this, the eight upper floors of one of New York's finest office buildings are in ruins through flames which were spread through the glass windows, from a fire in an adjacent building. The trifling resistance that glass offers to fire is now well known; and the question concerning the Conkey plant is whether a fire-fighting force in one of the rooms of the building could keep flame from entering from an adjacent department through the roof skylights. Probably it could do this, under favorable circumstances, but in other cases it seems likely that the smoke and heat might be carried in such volume through the broken skylights as to compel the defenders to retreat.—Ed.)

◆

THE HUGHES AIR LOCK; VALPARAISO HARBOR.

The late Mr. John Hughes, M. Inst. C. E., of England, was the engineer for the wrought iron pier built in 1873-83, in the harbor of Valparaiso, Chili, by the Chilian Government. This pier was made by sinking wrought-iron cylinders, 11 ft. 4 ins. outside diameter, through water 48 ft. deep, to a solid foundation, sometimes as much as 107 ft. below the water surface. These cylinders were filled with concrete and braced, and supported the pier platform. They were sunk by the use of the pneumatic process, and the novel air-lock employed is illustrated and described in "The Engineer," of Sept. 9, 1898, from which the following brief account is taken:



Section of Cylinder for Steamship Pier, Valparaiso Harbor, Chili, Showing Operation of Hughes Air Lock.

The main cylinders were made in 8-ft. sections, with angle-iron connections, and they were sunk from a temporary staging supporting a traveling crane. There were, in fact, two cylinders; an inner one, 8 ft.

in diameter, and made of ½-in. plate, and another one made of ⅜-in. plate; the annular space between the two was filled with Portland cement concrete after the bottom was reached, and this weight was sufficient to ballast the cylinder and counteract the buoyancy of the compressed air inside.

After the main cylinder was in the water and floating by reason of the unfilled annular space, a wrought-iron cover was bolted onto the inside cylinder, and on this cover two lengths of 3-ft. shaft cylinder were bolted, and additional lengths of these and the outer cylinders were added until the cutting-edge was on the bottom, with the top of the cylinder rising above the temporary staging. As the cylinder sank, the annular space between the two cylinders was filled with concrete.

The pneumatic apparatus was then put in place, and this was designed with the purpose of requiring no men to be under pressure except those actually engaged in excavation at the bottom. As shown in the figure, the two D-shaped cases, A, were provided with covers opening downward and opened or closed by an outside hand lever fixed on the bar forming the hinge, and passing out through a small stuffing-box; the joint between the case and the lid was made tight by an india-rubber ring attached to the lid. A similar ring was fastened underneath the bottom of the case, A, which was open, intended to form an air-tight joint with the bottom portion of the air-lock, or skip-case, B. This latter was suspended by two chains of gaged links, one on each side, passing around the chain-sheaves, C, so that when both chambers, A, are closed at top and compressed air is admitted to them, one skip-case, B, can be raised and the other lowered simultaneously, by means of a winch on the outside, with the main shaft passing through the sides of the lock in stuffing-boxes. As the top of the skip-case, B, comes in contact with the bottom of the chamber, A, the compressed air may be let out of A and B, and the skip removed; the pressure of the air within the main cylinder forces B against A and makes the joint tight in this case. The cocks for the inlet and outlet of compressed air are 1½-in. diameter, and are linked together so as to be worked by one lever from the outside; smaller cocks, of ½-in. diameter, are provided on the inside for the use of workmen passing in or out. The original article gives no dimensions for the lock chambers; but the cases, A, were apparently about 2½ ft. diameter and 3 ft. high, while B was somewhat less in diameter and about 4 ft. high.

The buckets or skips for hoisting the material from the bottom, were made to closely fit the inside of the skip-case, B; and to assist in dumping them, when hoisted from the skip-case by a steam crane, a pipe was run through each bucket near the bottom, from side to side. Through this pipe a bar of iron was thrust, as the skip was raised out of the air-lock, and to the projecting ends of this bar the tripping, or dumping chain was attached.

This air-lock plant was equipped with a signal gong, pressure-gage, safety-valve, and air-connections, fitted with a check-valve and stop-cock, to be used in the event of a rupture of the 3-in. hose-pipe leading to the air compressing plant. There was also a 3-in. valve and connections in the 8-ft. cylinder for ejecting water from the cylinder, otherwise than by forcing it out under the bottom edge. A small flexible pipe was provided for drawing off compressed air to work a pump for supplying water for the concrete, and a wire rope-ladder, hung beside the air lock shafts, enabled the workmen to pass to the bottom. The air-compressing plant was placed on the shore, and the compressed air was led in an iron pipe to the 3-in. flexible hose referred to.

When the cylinder had been sunk to the required depth, sometimes 107 ft. below the water surface, 8 or 10 ft. of concrete was carefully deposited in the bottom under air-pressure. This concrete was lowered in the skip-cases, B, and these were tipped like ordinary buckets. During the hardening of this concrete the safety valve came into play, in maintaining an even requisite pressure and obviating the possibility of the compressed air blowing out at the bottom and causing unsound work. Two men only were employed at a time under pressure in each cylinder, working in 4-hour shifts. While the usual results of working in compressed air were noted, there was only one death. This one fatal case resulted from the workman failing to give the signal that it was a man, and not material, that was coming up; the consequence was that the pressure was released suddenly and the man was paralyzed from the waist downward. He at once went under pressure again and was released gradually; but the mischief was done, and he died in the hospital, about three months later, from the indirect effects of the paralysis.

◆

A NEW AIR LOCK AND CYLINDRICAL WOODEN PNEUMATIC CAISSON FOR FOUNDATIONS.

An entirely new system of pneumatic caisson foundations is being employed in constructing the new residence of Mrs. Elliott F. Shepard, on 62d St., near Madison Ave., in New York city. In passing it may be noted that so far as we are aware, this is the first use of pneumatic caissons for dwelling house foundations, although they have been frequently employed heretofore in the foundations of mercantile and office buildings. In New York city particularly the value of this style of foundations has been fully proved, especially where deep foundations have to be sunk in close proximity to older buildings having foundations of shallower depth without injuring or disturbing the existing structures. The success in this direction is also exemplified in the present work. The chief interest of the work, to engineers, however, lies more especially in the cylindrical wooden stave caisson employed, the special form of caisson shaft, and the patented air lock designed by the engineer and contractor, Mr. John F. O'Rourke, M. Am. Soc. C. E., of New York city. The accompanying cuts illustrate these and such other features of the foundation construction as are of most interest.

General Description of Foundations.—The area occupied by the building is about 45 × 100 ft., and is rectangular in form. Eight pneumatic caissons filled with concrete and capped with brick masonry above the cellar floor carry the iron work for the building, which is five stories high. The caissons are placed in two rows of four caissons each along the two longer sides of the rectangle, the distance of the two rows apart transversely being about 25 ft. c. to c. of caissons for the front caissons and 29½ ft. for the others. Each caisson is 6 ft. 7½ ins. outside diameter, and they are sunk from 40 ft. to 52 ft. below the curb to solid rock. The material penetrated is rock filling, mud and clay, and hardpan and boulders, in the order named, and in the case of the front caissons an additional layer of clean, sharp sand just above the hardpan and boulders. The plant used in sinking the caissons and the progress and success of the work will be mentioned further on.

FIGS. 1 AND 2.—WOOD-STAVE CYLINDRICAL PNEUMATIC CAISSONS FOR THE FOUNDATIONS OF A PRIVATE RESIDENCE AT 11-13 EAST 62D STREET, NEW YORK CITY.

John F. O'Rourke, M. Am. Soc. C. E., New York City, Designer.

Cylindrical Caissons.—Figs. 1 and 2 show quite clearly the construction of the wooden caissons. Each is a cylinder 6 ft. 7½ ins. in outside diameter composed of staves cut with radial sides, and having inside angle hoops bolted to the staves. The staves are made of 4 × 6-in. plank dressed to 5½ × 3½ ins., and have 1-in. square slip tongue joints. At first these tongues were covered with whitelead, but it was found that this prevented the tongue from swelling and finally the painting was abandoned.

As will be seen from Fig. 2 and the general drawing, Fig. 3, showing the caisson, caisson shaft and air lock assembled in position ready for work, the wooden cylinder is provided with a metal cutting edge consisting of an angle and plate. Fig. 3 also indicates the construction of the double angle joint connecting two lengths or sections of wooden cylinder. The roof of the working chamber is formed by a ring-shaped diaphragm of steel attached at its outer edges to a special angle ring which was very strongly connected to the staves by a countersunk rivet in each stave, and to its inside edges was attached the bottom of the caisson working shaft. Fig. 2 shows a section of the steel roof ring lying inside the caisson cylinder. It will be noticed that it is detachable and can be used over and over again, like the caisson shaft and air lock.

Caisson Shaft.—The construction of the caisson shaft is shown by Figs. 3 and 4. Briefly stated, the objects sought in designing this shaft were to provide a shaft having no interior projections to catch and otherwise obstruct the hoisting of the bucket, and permitting of its use as a "man shaft" when fitted with a suitably designed lock for that purpose, and also one which would afford a ready means of escape by providing holds by which the men could climb up the inside of the shaft. It was necessary also that all of this should be accomplished without danger of the air escaping and without weakening or greatly increasing the cost of the shaft.

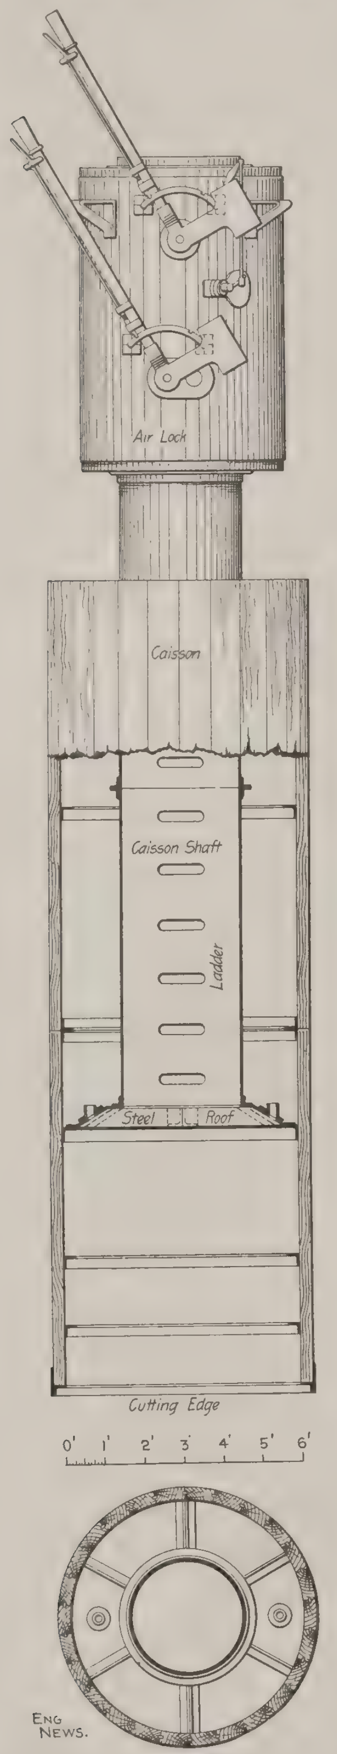

Fig. 3.—Sectional Elevation of Wooden Cylinder Caisson, Caisson Shaft and Air Lock Combined.

Referring to Fig. 4, it will be seen that the shaft is simply a steel cylinder, in one side of which is cut a series of horizontal oblong holes, one above the other, at convenient distances apart to enable a man to step from one to the other. These slots, it will be seen, form a ladder, no part of which projects into the interior of the shaft. To prevent the air escaping through the slots, they are provided with a cover of the same material as the shaft, which bulges outward enough to permit the insertion of the hand or foot into the slot. This cover extends the full length of the shaft, and is riveted to it at the edges, as clearly shown. To prevent the shaft from bulging under the air pressure or the cover plate from being forced inward by any ordinary accident, it is stayed by bolts, which extend through the cover into the shell of the shaft. The shaft, of course, may be provided with any number of these ladders which space will permit and which may be thought necessary.

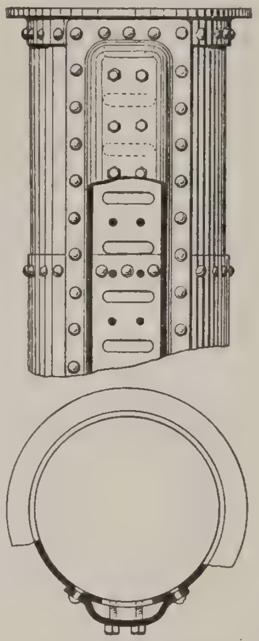

Fig. 4.—Sketch Showing Ladder Construction in Caisson Shaft.

Air Lock.—The several sections and elevations in Fig. 5 show the construction and operation of the air lock. The lock has an essentially cylindrical body, A, which has a top opening, B, and a bottom opening, C, of the requisite size to permit the passage of a bucket or cage through it. Around the top opening is a circular ring, D, on the inside. This opening is closed by the oppositely-arranged convex swinging gates, E, the meeting edges of which are packed so as to make an air-tight closure. The opposite edges are provided with flanges, F, adapted to close against the ring, D, these flanges having flap-gaskets which protrude into the air lock so that the air pressure striking them will make an air-tight seal by pressing them against the ring, D. While ordinarily all the pressure on the doors, E, is taken by the shafts, G, and the actual closure is made by the flap-gaskets, yet the ring, D, may be made to act as an emergency bearing to take the pressure.

The gates, E, are cut away at the center of the meeting edges, as shown at H, to receive and fit snugly upon the stuffing-box, J, banded with rubber, and having a hole through the center for the passage of the hoisting rope. The gates are hung by the arms, K, to the common shafts, G, one (M) being fixed to the shaft, and the other (N) running loose. This arrangement, by means of the bevel gears and idler m, n and o, allows the two doors to be moved in unison and in opposite directions. This hanging of the opposite gates on a single center obviates the necessity of piercing the shell in more than two places, and, therefore, reduces leakage and simplifies the construction. The manner of rotating the shafts, G, by the levers, O, is obvious from the drawing. It will be noticed that the levers have counterweights which balance the doors and thus enable one man to operate the lock.

The air lock has its lower end closed by similar oppositely-arranged swinging gates, P, which near their outer edges have the seats, Q, which fit against the ring, R, with gaskets to secure a tight fit. The castings forming the ring, Q, it will be noticed, have flanges, q, r and s, forming rungs continuing the shaft ladder previously described, and being continued itself by the ladder-like structure, S. Unlike the upper gates, E, the lower gates, P, are swung by the arms, T, from separate centers or shafts, U and V. The gate arms are rigidly fixed to the shafts, and turn with them. To secure opposite motion to the shafts one is operated by a spur wheel from the other, as shown at t and v, the actuating force being obtained through the lever, O. The admission and discharge of air to and from the lock is controlled by the three-way cock, X, operated by a lever and bevel gear and connected with suitable piping to the air shaft, there being no independent connections with the compressors, as is usually the case.

To operate the lock, therefore, the bucket being at the bottom, and the bottom gates, P, necessarily open, the bucket is raised up into the air lock and the gates, P, closed behind it. The air is then discharged by the valve, X, from the lock and the top gates, E, are opened. This allows the bucket to be hoisted out and dumped, or loaded, as may be desired. In the return process the bucket is hoisted into the lock and the top gates closed, care being taken to place the rope stuffing-box, J, approximately in place; air pressure being then admitted, the bottom gates are opened and the mitted, the bottom gates are opened and the bucket is allowed to descend into the working chamber. This operation usually takes about ten seconds, and is accomplished by one man without difficulty. While the drawings show the gates operated by hand levers, other methods may be employed. One of these is a system of oscillating cylinders, and such a system was described and illustrated in the original patent specifications, No. 591,633. After trying both systems the levers were found simpler and cheaper.

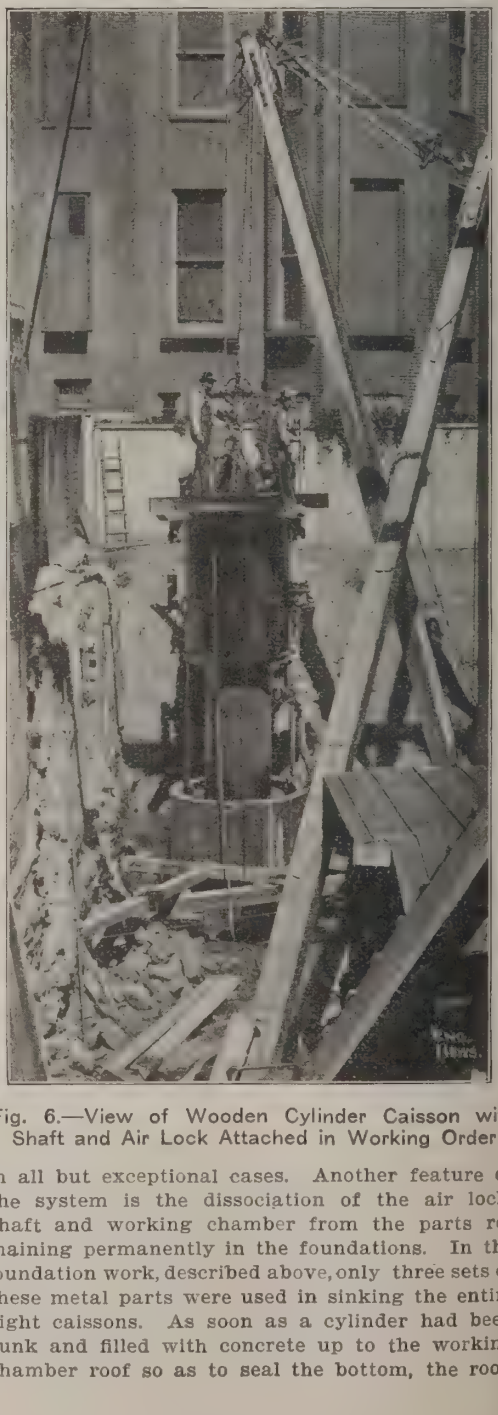

Fig. 6.—View of Wooden Cylinder Caisson with Shaft and Air Lock Attached in Working Order

It will be seen by examining Fig. 3 that when the bucket is at the bottom of the working chamber everything is open clear to the very top of the air lock, and with the ladders provided in the shaft and lock the men can, in the case of a sudden inrush of water, scramble to the top above danger in all but exceptional cases. Another feature of the system is the dissociation of the air lock, shaft and working chamber from the parts remaining permanently in the foundations. In the foundation work, described above, only three sets of these metal parts were used in sinking the entire eight caissons. As soon as a cylinder had been sunk and filled with concrete up to the working chamber roof so as to seal the bottom, the roof, shaft and lock were raised out and the remainder of the filling was done in the open air. A watertight layer of tar and tar paper was embedded in the concrete near the bottom of the chamber to ensure a perfect seal.

As indicating the rugged construction of the wooden stave cylinders as designed, it is stated that in sinking one of them 40 blasts were fired inside the working chamber, using a half a stick of dynamite each, and beyond some of the staves being scarred by flying stone no damage was done. The calking was not affected enough to cause any leaks, and the roof plates and connections were not broken, although the concussion was sufficient to jounce the load of pig iron resting on the roof an appreciable distance into the air.

Elevation.

Sectional Elevation.

FIG. 5.—PLAN, SECTIONS AND ELEVATIONS SHOWING CONSTRUCTION AND OPERATION OF AIR LOCK.

Fig. 6 shows quite clearly the appearance of one of the caissons with the shaft and air lock complete; the fall block attached to the air lock being operated from the boom of a derrick not shown in the engraving. At the time the photograph was taken the air lock had just been hoisted to place. After this was done the falls were unreaved and the excavating bucket was attached to a "single whip." Two derricks were employed, placed near the ends of the lot and covering the entire area with the combined swing of their booms. Between the derricks were situated the two hoisting engines, and their boilers and the duplicate air compressors with their receiver. With this plant the cylinders were sunk to the depth before stated, in periods ranging from 30 hours to eight working days. The largest amount of time was consumed in penetrating the rock fill. Three men were worked in the caisson chamber, one operated the air lock, and another regulated the admission of the air. Absolutely no disturbance of the neighboring foundations was caused. The contractor was Mr. John F. O'Rourke, M. Am. Soc. C. E., the inventor and patentee of the caisson plant used. We are indebted to Mr. O'Rourke for the information from which this article has been prepared. The architects for the building were Haydel & Shepard, of 156 Fifth Ave., New York city.

◆

BETWEEN THE MINE AND THE SMELTER.

Let us suppose that, as in nine cases out of ten is the fact, you have decided to locate a smelter at a point where fluxes and fuel are more available than at the mine, or to ship your ore to some custom works, at a point so distant in either event that it necessitates railway transportation. The first problem which will usually concern you will be that of freight contracts. There are some railways, like the Great Northern, for instance, that were built through an almost uninhabited country with the express purpose of building up that country and reaping profits in future, and such roads make very liberal rates to miners and smelters along their lines, as well as to other settlers. But there are other roads primarily built perhaps to secure land grants, or, which run from one populous district to another, almost regardless of grades, and, to some extent, of distance; the longer the distance the more land to be obtained from the government. The policy governing such roads has, generally speaking, been unfavorable to industrial development, unless indeed at points where some of the gentlemen interested in the railway were interested in the local development.

When my firm began receiving shipments from Montana, in 1880, the freight rates were from $40 to $60 a ton. They probably do not exceed $18 at this time. One of the most conspicuous instances of the separation for economic reasons of works and mines is that of the Boston-Montana Co. in the state of Montana. Their mines are at Butte, and their works at Great Falls, a distance of 175 miles apart, with one of the main ranges of the Rocky Mountains between. At Great Falls was unlimited water power and cheap fuel; at Butte was not enough water for concentration, and expensive fuel. Before the works at Great Falls were started a freight contract was entered into, the rates of which are popularly supposed to be not much over $1 per ton of ore for this 175 miles of haul over an elevation of 6,000 ft. By way of contrast, I examined a mine in Nevada, only 100 miles from fuel and water by rail, but $3.50 per ton was the lowest freight named for a 7% copper ore.

Recently, competition between railroads and falling prices for metals, have introduced into the question of transportation a new factor, that of the application to ores of the "milling in transit" applied to wheat. You know that a railroad will take a contract to carry wheat from Dakota to New York at a certain price, consenting that the wheat shall be stopped at Minneapolis, turned into flour, packed in barrels, and the flour go forward under the original contract. There are likewise shipments of ores in which the freight contract is based on the number of pounds of copper and lead which they contain, as determined by assay, the contract covering the transportation of the ore from the mine to the smelter in the Middle West, and the bullion from the smelter to the Eastern market; all considered under one contract, not completed until the bullion is delivered. You can readily see the necessity for carefully considering the question of transportation before deciding where to locate works, from this brief outline.

There is still another question of transportation which has been often overlooked by producers of precious metals by smelting, whose product is in the form of rich lead or copper bullion; and when I have suggested that it was worthy of consideration, I have been met sometimes with incredulity until the interested parties began to figure: that is, the difference between freight and express rates on precious metals from the Rocky Mountains to, say, New York.

Take, for illustration, the Anaconda Copper Mining Co. The freight on its product in the form of converter bars or anodes, probably does not exceed $15 per ton to the Atlantic seaboard, and, of course, the gold and silver contained in the copper pay the same freight by the ton. During the fiscal year ending June 30, 1896, the Anaçonda company shipped about 108,000,000 lbs. of copper, containing about 6,000,000 ozs. of silver and 16,000 ozs. of gold. The freight on these 206 tons of gold and silver at, say, $15 a ton, amounted to not much over $3,000; but had this material been refined entirely in the West, and the fine gold and silver all been sent forward by express, the expressage and insurance at 2 cts. per oz. would have amounted to $120,000, difference enough to erect an electrolytic refinery in the East from the saving of two years. In the East, labor is cheaper, sulphuric acid is cheap, and there is a market for the incidental sulphate of copper produced. Then again, the distance from market of the finished product has great influence with the location of works, especially for ultimate refining, as freights are higher as a rule on finished products.

As a result of these conditions, slowly realized, sentiment at present is strongly in favor of the erection of copper refining works on the Atlantic coast, or at least in the East, and it is doubtful whether any of the large copper producers would have put up their electrolytic plants in the West had they realized that the conditions of to-day would prevail, unless it be those fortunate enough to be located on the Great Northern, with the water power of the whole Missouri at Great Falls to draw upon.

Of the 15 electrolytic refineries in the United States, all are east of Chicago, except 3. One-half of the output of the Anaconda is refined in Baltimore, and for the next two or three years all of the United Verde Copper Co.'s output, of Arizona, will also be refined near the port of New York. The entire product of the Canadian Copper Co.'s copper-nickel mines at Sudbury, Ont., is also refined near New York, and all the copper producers west of the Mississippi treat their material, ultimately, in the East, except three. Of course, what has been said does not apply to gold milling, nor in so great a degree to lead smelting, although much Western lead is refined in the East.

While the mining engineer and metallurgist—unless, indeed, the electrical engineer can be called a metallurgist—will find their greatest opportunity in the West, the analytical chemist, assayer and sampler, will find, in all probability, his largest opportunity in the East, or at least as far east as the great manufacturing and refining centers of Omaha and Chicago. He must remember, in choosing his location, that not alone is he to be called upon to handle material going to buyers' works, or those of refiners on toll, but also material destined for export to Europe, and, moreover, a commercial laboratory should seek all branches of analysis.

In 1880, when my laboratory was opened in New York, there was very little assaying of ores or metals at this port, excepting iron ores. The chief support of an analytical laboratory was from manufacturers of chemicals, fertilizers, etc. In those days chemists received from $5 to $7 for a nitrogen determination, and $4 for determina-

---

*Extract from a lecture delivered before the graduating class of the School of Mines, Columbia University, and published in the "School of Mines Quarterly," July, 1898.

tion of phosphoric acid. To-day, some are glad to receive $1 for nitrogén determination, and from $2 to $2.50 for phosphoric acid. Not only has the price fallen, but the demand for rapid work has become more exacting. One of the first things the chemist discovers on graduation is that he must invent short-cut methods if he would keep his business. I was "brought up" on Fresenius and taught, for instance, that phosphoric acid could only be safely determined after fusion, separation of silica, solution in nitric acid, precipitation as phospho-molybdate; this after 12 hours' standing dissolved in ammonia, precipitated as ammonia-magnesia phosphate—after standing 12 hours filtered, ignited, etc., etc.

This means at least 48 hours; but I was startled upon opening my laboratory to have the first man who brought in a sample of phosphate say he must have the results before 3 o'clock the same day. All business changes. The assayer of the last two decades has seen the testing of chemicals, drugs, etc., almost disappear from his laboratory, if unwilling to accept nominal prices, and sometimes because trade customs have eliminated analysis. For instance, all the bleaching powder and all the alkalis imported used to be sold on American test. Now the European test is accepted on these in spite of the fact that the trade chemists of England still use an admittedly erroneous atomic weight in calculating the analyses of potash compounds. The analyist, moreover, finds keen competition in his business arising from old established firms, nevertheless alive to modern methods, or from other chemists who can, and will, perhaps, work more cheaply than he. There are foreigners in this business here, who in some cases, live over their laboratories, or in them, whose highest ambition is, apparently, an income of $100 per month, and who have brought the price of sugar testing, for instance, from $2 per sample down to 25 cts., within my memory. Then, there are trade newspapers, who, by way of advertisement, have laboratory annexes, and at reduced rates issue certificates of test for dye-stuffs, groceries, drugs and chemicals; and then in some centers there is the additional competition of men employed by manufacturing or other institutions, with assured salaries, but with the privilege of doing outside work, who do not depend upon their laboratories alone for a living, and who can cut prices proportionately. There is nothing whatever in this competition that is unprofessional or unfair, but it must be reckoned with, and a specialty should be chosen, if possible.

While the analytical business has suffered, the assaying of ores and metals has increased in the East, and in the '80's there seemed to me to be an opening for an ore sampling plants at this port. Here again the transportation problem had to be considered. It is vitally important for such works to be on a line or at a point where railway pools cannot bottle you up, as it is doubtful if your prestige and reputation would be sufficient to bring business to your works, in the face of switching charges or higher freight rates than those obtained over other roads and at other points.

In locating our sampling works, having ascertained the amount of business likely to be brought to the road upon which we located, we interviewed the general managers of several trunk lines terminating at this city. Their reception was characteristic of the roads. The manager of one line did not exactly quote the language of its "Commodore" when he expressed contempt for the general public, but he evidently had no use for ore samplers. Another line offered a piece of ground on the meadows several miles from water transportation, but would make no guarantee against competitive freights. A third road not only gave the land at a nominal rental, but contributed a considerable proportion of the labor and material necessary to erect the works, entered into a contract that it would protect the sampling works against cut rates offered by other roads; and in addition, agreed that ore or other products coming to this port could be stopped not only for sampling but for storage, and upon completion of the sampling or storage, the road would take them over again and complete the haul and lighterage under the original bill of lading. This is storage in transit. It may be said that this road construed this contract with extraordinary liberality. For instance: When, in 1889, Mr. Sécrétan, of Paris, cornered the world's output of copper, buying the entire visible supply, and the entire product of nearly all the mines, sampling was pretty lively at the works mentioned. As the syndicate approached its disastrous end, copper matte began to halt at the sampling works until nearly 8,000 tons had accumulated. Then the syndicate went to pieces, and its creditors fell foul of one another in dividing up the assets. The copper matte was the subject of protracted litigation. It remained in the sampling works—most of it—seven years, at the end of which time the original bags had rotted and carloads were inextricably mixed. Upon the settlement of the dispute at law the matte was ordered out. The musty bills of lading and liter notices were produced, and the railroad sent its empty cars, transported and lightered to ocean steamers some 7,000 tons, seven years after it had started from its Western point of production. These sampling works in turn brought to the Erie Ry. for several years a business of 50,000 tons annually. Choose your location with care.

We have found as another bit of experience that not simply must one be sure of the road's ability to meet its obligations, if we are obliged to tie ourselves up to one line, but must forecast as far as possible conditions of routing and export. Some two years ago roads running southeast from Kansas discriminated against the port of New York, and not only did they quote a lower freight to Gulf ports, but via Gulf ports to Europe. The result was, much of our sampling had to be done on the docks at Galveston, New Orleans, etc. This has temporarily been put a stop to by the Cuban war, and New York is again securing the bulk of lead and copper freights, even when the material is produced in Arizona.

Of late years there has grown up in this, as in other lines of business, the endeavor to get rid of the middle man—in this case the public sampler and assayer—and buyers and sellers have entered into contracts in which the sampling is to be done at buyer's or seller's works by representatives of both parties. There have been such contracts recently entered into, and questions are already arising which cause one or both of the parties most interested financially to regret them. Buyers and sellers are necessarily suspicious of one another on general principles, especially in dealing with material of great value, and some are beginning to realize that it is unwise to place themselves under suspicion, however unjust. In one works, owned by the same people who own the mines, such serious differences arose recently between the respective superintendents that it ended in an agreement, not only that they should revert to independent sampling, but that the material should be sampled on neutral ground. It is perhaps justly said that it is too much to expect of average human nature that impartial sampling shall exist at the works or the mine of an interested party. The office sees so much lead, copper, gold and silver charged on the books and holds the works responsible for this amount either in inventory or shipments. The smelter, therefore, must "protect itself against the office," and if mistakes are made they are apt to be on the safe side where sampling is at either seller's or buyer's establishment.

Neither sampling nor assaying is an exact branch of science especially when dealing with materials containing the precious metals. Your practice in assaying has shown you what variation you can get in any samples, as you vary fluxes, temperature and time of fusion or cupellation. Let me strongly advise you to make every effort, whether you are a seller, buyer or sampler of ore or furnace products, to have the sales contract specify how the assay shall be made.

Now as to sampling methods: In the early '80's our chief export of furnace material was in the form of copper ores. We sampled hundreds of cars of ore from Montana, running 50 to 60% of copper. The lead ores then, as now, stopped in the West, only the bullion coming to the seaboard for export or refining. Then came a period of enormous exports of copper matte; next began the era of bessemerizing, applied to copper, and converter bars became the chief support of the sampler. These mattes contained less than 30 ozs. of silver to the ton on the average, and no silver was paid for unless there was over 30 ozs.

Then the electrolytic refinery came in, and as silver and gold were more easily extracted, the mines sought out gold and silver-bearing ores and run up the values present. To-day, the exports and treatment of furnace products near New York consist of quite two-thirds converter copper bars, as compared with one-third mattes.

THE EXPOSURE FIRE IN THE HOME LIFE INSURANCE BUILDING, NEW YORK CITY.

One of the most severe attacks of fire which a modern tall, steel skeleton, fireproof building, has ever undergone was sustained by the 16-story office building of the Home Life Insurance Co., at 256 Broadway, New York city, on the night of Dec. 4. This building was erected in 1893, and was flanked on one side by the 14-story office building of the Postal Telegraph Co., and on the other side by the 5-story clothing store occupied by Rogers, Peet & Co. The relative location of the three buildings is shown by Fig. 1, from which it will be seen that the 5-story clothing store abutted close against an air and light shaft which recessed the north side of the Home Life Insurance Co.'s building. It was this 5-story building which first caught fire, and which was the torch that communicated the flame to the other structures. The conditions were, indeed, almost typical of what may be seen repeated a score of times in every large city; viz., a tall, steel skeleton, fireproof office building standing by the side of a low, combustible structure whose destruction is nearly certain if fire once catches it, and which is, therefore, a constant menace to its costly neighbor.

The Home Life Insurance Co.'s Building is of the steel skeleton type, all the exterior walls except the front wall, which is self-supporting, being carried by the steel frame. The building has a frontage on Broadway of about 56 ft., and a depth of 107 ft. 6 ins. Two air and light shafts, faced with white enameled brick, with terra cotta trimmings, recess the north and south sides. The exterior walls are brick, except the front wall, which is of white marble elaborately carved. The floor girders run transversely across the building, there being one row of interior columns, and are knee-braced to the columns to resist the wind pressure. The floor beams are supported at each end by angle brackets attached to the girders, and are spaced about 4 ft. 6 ins. apart c. to c. The columns are H-section, made up of plates and angles.

All the steel work is protected by a fireproofing of clay tile. The floor arches are of hard-burned tile, and are 10 ins. thick and of side construction, each arch having two skewback blocks turning underneath to protect the lower beam flanges, four haunch blocks, and a key block. Each block has two horizontal and one vertical interior ribs or diaphragms. The partitions were of 4-in. porous terra cotta tile, the upper 4 ft. in the hall partitions being taken up by windows. The column tile were porous terra cotta tile, ribbed inside to give two air spaces. The main girders, which projected down below the ceilings, were filled in above the flanges with tile blocks, and had their lower flanges wrapped with expanded metal lath. The whole was haunched around by a thick coat of plaster. A plaster finish, of course, covered the column and partition tile.

Fig. 1.—Sketch Map Showing Location of Burned Buildings in the Fire of Dec. 4 at Broadway and Warren St., New York City.

The foregoing gives a fairly complete idea of the fireproof construction. Another structural failure of the building which it is important to mention, however, is the light shaft adjacent to the Rogers, Peet & Co. store. To the level of the sixth floor this shaft was inclosed by the wall of the store, but above this point it was open. The two side walls of the shaft had four windows each at each floor, occupying practically the entire area. The other side of the shaft had two smaller windows at each story. None of these window openings were protected by shutters, and it was through them that the flames penetrated the offices of the Home Life Insurance Co.'s Building.

As already stated, the store occupied by Rogers, Peet & Co., and filled with haberdashery, clothing and the extensive shelving and counters of a store of this character was the torch. According to all accounts, it furnished a very fierce fire, the flames of which were driven into the light shaft as a flue by a very severe northeast wind. These flames soon penetrated the unprotected window openings and set fire to the office furniture, fittings and woodwork; thus extending gradually to the farther sides of the building. An excellent description of how the fire made its progress is contained in the following excerpt from the New York "Sun":

> The clothing store was all in a blaze in a quarter of an hour. Then it burned as a whole until the floors fell, one after another. At 11 o'clock there was nothing left to burn. Meantime, the big insurance building, against which this white hot mass of fuel had been sending up steady sheets of flame for a full hour, had just begun to catch fire, this notwithstanding the fact that the windows had no iron shutters on them.
>
> In the middle of the north side of the Home Life Building, the deep light shaft that ran from the bottom to the top was entirely open on the side toward Warren St. When the clothing store became like the inside of a stove the airshaft, far up to the height of the clothing store, was a most effective chimney. The flames swept up that shaft in a solid column, spreading out in clouds of sparks when they reached the top. When the flames above the roof of the clothing store began to die down a little it was seen that every window along the shaft was crackling and blazing. The woodwork around the windows seemed to be all on fire at once.
>
> On every floor the firemen were fighting to keep these flames on the light shaft windows confined to the windows,

Hose had been carried up the elevators, which were in the middle of the building. But the heat was so great that it was impossible for the men to work in the rooms along the shaft. It was half past 10 o'clock when the flames broke into the twelfth floor of the building and began to work away from the shaft and into the building. The fire reached the elevator shaft, in the center of the building, at a quarter of 11.

There are fire mains in the building with connections on the street that the engines can pump water into, and outlets to which hose and nozzles can be attached on each floor. With the constant aid and reinforcement of the furnace in the airshaft, these inside mains were powerless against the flames that were eating from the airshaft toward the front and the back of the building. When the fire once had a firm grip on the twelfth floor there was nothing to do but let it burn. From the buildings on the other side of Warren St. no stream could be sent that would half way reach it.

Here came the exhibition of the difference between the modern construction of the Home Life Building and the old-fashioned plan of the clothing store. This one floor was so thoroughly on fire that spouts of flame were shooting from every window, but the windows of the floor below and the floor above, except on the airshaft, were dark. The fireproof floor kept the fire on each story separate from the others. But the firemen could not keep up the fight above the twelfth floor. Window by window, from office to office, the fire worked its way forward through the 14th floor, skipping the 13th. It worked along the offices on the north side of the building until it reached Broadway, and then south to the Postal building, the windows of each office popping out by pairs. The 14th floor was as thoroughly afire as the 12th at 11:25 o'clock. Ten minutes later the 13th floor windows began to light up. But the floors were standing the test well. The fire was working not from above or below but from the airshaft inward. This was true of every floor that burned. First the heat drove the firemen out, and then the flames followed them.

Substantially the same account of the progress of the fire is given by other observers; that is, that the fire caught and progressed on each floor independently, and did not communicate to any extent from one floor to another. An examination of the burned floors the day after the fire also indicated that the elevator shaft and stairway had not acted to any extent as passages for the flames from story to story. The floors proved to be almost perfect barriers. Only two floor arches altogether had broken through, one on the 15th floor and the other on the 10th floor. On the 10th floor the failure of the arch was due to the fall of a safe. From all the evidence which is available, therefore, it seems fair to assume that there was almost no communication of the fire from floor to floor inside the building. In this respect the fireproof construction served its intended purpose almost perfectly.

The greatest damage was done from the 11th floor up, and in that part of each floor comprised in the wings on each side of the light shaft. It was evident from the ruins that the flames entered the windows on the sides of the shaft, and worked inward and around the front and rear walls to meet in the rooms opening onto the light shaft adjacent to the Postal Telegraph Co.'s Building. The damage was greatest in the rooms near where the fire entered and it gradually decreased as the center of the opposite side was approached. It was also more severe, taking the building as a whole, in the rooms fronting on Broadway. The windows opening onto the elevator wells did not communicate the flames to any very great extent, owing largely to the fact that the elevator enclosure and the adjacent hallway and staircase finishing was incombustible, being either stone or metal.

From the 11th to the 15th floor, inclusive, the damage was about the same on each floor. The condition of the floor arches has already been stated. The partitions were broken down in places and the doors and windows and their casings in the partitions were burned away. Much of the partition damage was evidently done by the firemen, who knocked them down to get at the flames, but water and fire were also responsible to a great extent. The column protection was knocked off in patches, but not very generally. The lower flanges of the floor beams still retained their fireproofing almost perfect as a rule. The main floor girders, which projected below the ceiling, however, had suffered more; the tile filling blocks and the expanded metal and plaster flange wrapping in the places where the fire was hottest being quite frequently either torn off entirely or else hanging loose, leaving the metal bare. The appearance of the metal indicated, however, that the protection had stood long enough to preserve the beams from injury.

The examination, in fact, showed practically no damage done to the steel work, with the exception of two girders on the 15th floor, which had been left unprotected. It may be possible, of course, that a more minute inspection when the debris is removed will show somewhat more damage to the steel framework than now appears; but it hardly seems likely that it can be serious enough to require any great amount of new material. The brick exterior walls may possibly have to be taken down in a few of the top stories, but this will not be known certainly until a closer examination can be made. The marble front, however, in the stories where the fire was hottest is so badly cracked and spalled away that it will certainly have to be rebuilt.

From the 11th floor down the damage gradually decreases, until on the 7th floor it is due mostly to smoke and water. This was probably owing to two things. First, the blast of the flames against the light shaft windows was greater above than below the 7th and 8th floors, but second, and more important, the firemen were able successfully to use their hose up to the 8th story. Above this point the pressure and volume of water obtainable with the ordinary fire apparatus were not efficient against so hot a fire. This was recognized by the fire department at the start, and the 8th floor was established as the level below which the flames must not be allowed. Above that level, after they were once established, they were allowed to burn unhindered.

From what has been said it will be generally admitted by those competent to judge, we think, that the value of its fireproof construction was proven by the Home Life Insurance Co.'s Building. Its weak feature was the unprotected window openings in the light shaft. To this single instance of neglect, we believe, the damage of the building by fire was entirely due. Indeed, we have no hesitation in saying that had the light shaft windows been protected by good fireproof shutters, and been set in metal frames and sash, the flames would never have entered the building with the firemen behind with hose to keep the shutters cool. The building was well fireproofed in every respect except to withstand an exposure fire, and with the tinder-like clothing store by its side an exposure fire was the one which the builders had most reason to expect. As it was, the building kept the fire confined so that its spread was easily prevented under conditions of high wind and bad facilities for fighting flames so far above the ground. Had the whole block been made up of buildings like the clothing store, it is safe to say that it would have been swept clean by the conflagration.

The total damage done by the fire is now estimated at about $600,000. No one was killed, and only two or three of the firemen received slight injuries. For information respecting the constructon of the Home Life Insurance Co.'s Building we are indebted to Napoleon Le Brun & Sons, 1 Madison Ave., New York, the architects. A personal examination of the burned building was also made the second day after the fire by a member of the editorial staff of this journal.

NEW BATTLE REGULATIONS FOR WARSHIPS have been framed by the Navy Department, as a result of experience in the late war. The new instructions leave little to the discretion of officers. Above all else woodwork must be sacrificed in an emergency to guard against danger of fire. All furniture will be reduced to a minimum in war times; camp-stools will take the place of chairs, and swinging tables will replace the substantial mahogany-tables of peace times. All articles on deck not needed in action must be stowed below or cast overboard; proper fire apparatus must be installed and hose led to all parts of the ship with a full head of water constantly maintained; all glass, lights and illuminators above the engine-room are to be taken away; and even boats are to be disposed of, because they would be riddled and useless anyhow in close action. Guns are to be loaded as soon as the ship leaves port, and projectiles are to be kept conveniently near; chains are to be unshackled at the first shackle, so that if the anchor is cut away the whole chain will not go with it. Ships are to be painted a dull gray, with a yellowish shade, as approximating most closely the color of rock, and of an obscuring horizon.

ANOTHER ELECTRICAL EXHIBITION will be held in New York city in 1899. This was decided at the annual meeting of the stockholders, held Nov. 22, at which the following officers were elected: Pres., C. O. Baker, Jr.; Vice-Pres., F. W. Roebling; Secy. and Treas., Geo. E. Porter; General Manager, Marcus Nathan.

A MOTOR CARRIAGE CONTEST was held in Boston, Mass., on Nov. 9, under the auspices of the Massachusetts Charitable Mechanics' Association. There were four types of contests—speed, brake efficiency, manageability, and hill-climbing. The De Dion gasoline tricycle covered two miles in 5 mins. 1⅗ secs.; the Riker electric carriage stopped in 6 ft. 1 in. The De Dion tricycle, 3 ft. 4½ ins. wide, won the manageability contest, which consisted in passing between six sets of posts and turning around and coming back to the line. The Riker carriage, with a width of 4 ft. 8 ins., also made an excellent showing. In the hill-climbing contest, the lighter carriages made the best showing. Prizes to the amount of $1,100 were awarded.

A TELEPHONE CIRCUIT OF 1,900 MILES was talked over on Nov. 28 by Mr. Charles J. Glidden, President of the Southwestern Telegraph and Telephone Co. Mr. Glidden, from his office in Little Rock, Ark., held a distinct conversation with the office in Boston, Mass. Satisfactory tests were also made from the Little Rock office with Memphis, Chicago, Minneapolis, Dallas and Galveston.

500,000 TONS OF STEEL RAILS were ordered in three days, Nov. 25, 26 and 28. Of this amount 275,000 tons were booked by the Carnegie Co., and 225,000 tons by the Illinois Steel Co., which is now a part of the Federal Steel Co. The prices mentioned are $19 per ton at Chicago, and $18 at Pittsburg.

FREIGHT RATES from Duluth to New York by all-rail routes are said to have been recently quoted as low as 10 cts. per 100 lbs., or $2 per ton. Calling the distance 1,500 miles, this is equivalent to only 1⅓ mills per ton-mile. The "New York Journal of Commerce" also says:

> It is reported that early last week one of the lines made a contract with a large exporting firm to carry wheat from Chicago to New York for 8 cts. per 100 lbs. From this rate is to be deducted 3 cts. per 100 lbs. for lighterage in New York, making a net rate for the railroad of only 5 cts. A rate of 9 cts. per 100 lbs. on wheat from Chicago to Baltimore was made recently by another line, but no lighterage charge was to be deducted from that figure.

SMOKE PREVENTION IN PITTSBURG, PA., is to be considered by a commission, which Director E. M. Bigelow, of the Department of Public Works, has asked the city council to appoint.

A CUSHION TIE-PLATE for deadening sound is being used abroad on street railway lines. This mat, according to "Iron Age," is made of wool thoroughly impregnated with oils and the whole covered with a mixture composed of glue, sodium bichromate and formaldehyde. The mat is then compressed to form a plate, the thickness depending upon the conditions of service. The material is also recommended for use under engine and machinery foundations.

BOOK REVIEWS.

DISTRIBUTION DE L'ENERGIE PAR COURANTS POLYPHASES.—By J. Rodet, M. E. Paris: Gauthier-Villars. 5½ × 8¾ ins.; paper; pp. 338; illustrated. 8 francs.

This book presents the subject of distribution of energy by electricity by means of alternating currents, of two, three or more phases. The present state of the art is briefly treated, the effort being to give a clear insight into definite practice rather than to present a theoretical discussion of non-essential matters. By this we do not mean that equations and mathematics are entirely missing, for this would be a harsh criticism, as it is impossible to enter into the realm of alternating currents without employing a certain amount of mathematics. The equations included are essential and are given in a brief but clear manner. Important relations and principles are given in italics, while the general text is simple, straight forward language. Time has not permitted more than a casual examination of the book, but such items as have been examined indicate that the material contained is reliable.

There are seven chapters in all, covering the history and general principles governing the two-phase and three-phase currents, the generation, transmission, transformation use for motors, instruments, and last a description of several installments using polyphase apparatus.

THE DESIGNING OF CONE PULLEYS.—A Non-Approximate, Graphical Solution for the Problem of Proportioning Cone Pulleys, with Concise, Practical Rules. By Walter K. Palmer, M. E., School of Engineering, University of Kansas, Lawrence, Kan. Pamph.; 6 × 9½ ins.; pp. 35. Price, 50 cts.

The mathematical analysis of the solution of the cone pulley problem is complex, and all practical approximate solutions hitherto proposed are either inconvenient to use or otherwise unsatisfactory. Mr. Palmer takes the analysis given in Reuleaux's "Constructor," modifies it at one stage so as to make a more simple graphical construction, and then develops a new diagram from which the problem can be completely and easily solved, for all practical conditions. The author seems to have made a most valuable contribution to the subject.

THE NEW YORK MEETING OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

We gave last week an account of the sessions of the meeting held on Tuesday and Wednesday, Nov. 29 and 30. The session on Thursday morning was devoted to the presentation and discussion of professional papers. The first paper was by Prof. C. V. Kerr, of Chicago, entitled "Theory of the Moment of Inertia." The paper is long, abstruse and mathematical, bristling with diagrams and calculus. The author has a theory that the moment of inertia is something different from what it is said to be in the text-books. Those who took part in the discussion held that the books were right and that the paper was all wrong.

The next paper was entitled "Improvements in Steam Boilers," by W. Barnet Le Van, of Philadelphia. It described a horizontal return tubular boiler, with the tubes placed higher in the shell than usual, so as to raise the water level nearly to the top of the shell, thus lessening both the area of disengaging surface and the steam room. It was provided with a long horizontal steam drum, connected to the boiler by a single neck. The paper was roughly handled in the discussion. The boiler was condemned as being no improvement over the plain horizontal tubular boiler, and it was shown that the author had described the same boiler in the Journal of another society as much as 13 years ago.

The next paper was by R. Van A. Norris, of Wilkesbarre, Pa., entitled:

"The Generation and Utilization of Steam by the Lykens Valley Coal Co. and Summit Branch Coal Co., Dauphin Co., Pa."

The paper describes the results of investigations made to discover, and, if possible, to remedy a large discrepancy in the amount of coal used for firing boilers at the two collieries. The work done by the engines at the two collieries was about the same, but at the Lykens Valley mines the boiler horse-power was 3,323 and the coal used per month of 26 working days 4,381 tons, while at the Summit Branch mines the boiler horse-power was 5,313 and the coal used 7,306 tons. The paper includes records of tests of boilers, and engines, indicator cards, investigations of leaky pipes, loss by friction, etc. All sorts of losses of steam and of coal were found; cylinder boilers with stacks red hot, engines so greatly underloaded as to cut off at less than 5% of the stroke, other engines without lap on the valves, carrying steam full stroke, leaky pipes and valves, blowing off of steam with drips from pipes, on account of the absence of traps, etc. A great waste was due to the use of steam jet blowers for forcing the fires under the boilers, some of them taking about 8% of the whole amount of steam made by the boiler.

The discussion of the paper brought out the fact that some of the pumps were over 25 years old. An experiment on fans and steam jet blowers was referred to, in which the steam jet required over 38 HP. of steam and the fan not over 5 HP.

Mr. John A. F. Swenson, of Chicago, then read a paper entitled:

"The Valve Gear of the Willans Engine."

The Willans engine has been well known for many years in England, but is much less known in this country, although it has been made in Chicago for some years. The paper describes the action of the hollow piston rod, which performs the function of a seat for all the valves. The engine may have applied to it an automatic cut-off, the arrangement for effecting the variable cut-off being a rotary sleeve surrounding that portion of the hollow piston rod which travels in the steam chest, the rotation being effected by a shaft governor.

A summary of the advantages claimed for this valve gear is as follows:

> Minimum number of parts and simplicity of form and construction; a free inlet and release, and a cut-off so sharp as to rival even a Corliss; a balanced valve of the piston type, with very small clearance spaces, and which by virtue of its position is easily kept steam tight; great facilities for varying the cut-off; perfect adaptability to the difficulties of high rotative speed.

One shortcoming is that the limit of its general adoption is reached in an engine having single-acting cylinders only. Another is the difficulty of arranging it to run reversing.

Mr. J. H. Vail's paper on "A Cooling Tower and Condenser Installation" was next considered. We give an abstract of this paper elsewhere in this issue. A long discussion followed. Mr. F. Meriam Wheeler exhibited some drawings showing recent arrangements of cooling towers, condensers and air pumps, including one of a duplex pump, in which one of the pump cylinders handled the water from the jet condenser while the other one pumped the air and vapor.

The next paper was by Prof. D. S. Jacobus, of Hoboken, N. J., entitled "Methods of Testing Indicators." It describes the method used at the Stevens Institute of Technology, which the author considers superior to the mercury column method. No discussion followed the paper.

"The Variation of Belt Tensions with Power Transmitted," by Prof. W. S. Aldrich, was the next paper. The object of the paper is stated to be to open up a discussion of the questions: In what way are the belt tensions altered as the load is applied? What effect has the change of the load on the sum of the tensions? Is there any relation between the belt tensions which does not involve the coefficient of friction? The author condemns the old logarithmic formula for the ratio of the tensions on the tight and slack sides, and derives an empirical formula from the results of the experiments of Mr. Wilfred Lewis, as follows:

$$\frac{T_1}{T_1 - T_2} =$$

e raised to a power whose exponent is the fraction

$$2\,T_2 \div (2\,T_1 - T_2),$$

in which T_1 is the greater and T_2 the lesser tension, and e the base of the Naperian logarithms, or 2.7183. Written discussions were presented by Mr. Lewis, who disputed some of Prof. Aldrich's conclusions, and by Mr. Carl G. Barth, who gave a new logarithmic formula, based on theoretical considerations, which is more formidable in appearance than either the old established one or the one proposed by Prof. Aldrich. Mr. Barth's discussion, when printed in the Transactions, will be interesting to those who enjoy studying the mathematical theory of belt tensions

On Thursday afternoon a visit was made to the General Post Office, on invitation of Postmaster Van Cott, to inspect the Batcheller system of pneumatic transmission. The system is working to perfection, and the machinery is a marvelous example of inventive and mechanical skill in solving a most difficult problem.

No programme was prepared for Thursday evening, and the members were left free to their own devices. At the session on Friday morning the first paper was one by R. S. Hale and Henry J. Williams, on

"The Calorific Power of Weathered Coals,"

This paper gives the proximate and ultimate analyses of eight different coals, both before and after weathering. Crushed samples of each coal were exposed out of doors for eleven months. The heating values were calculated from the ultimate analyses by Dulong's formula, and from the proximate analyses by interpolating them on a curve derived by Mr. William Kent from the calorimetric results obtained by Mahler on European coals. Direct determinations of the heating power of three of the coals were also made by Mr. Williams' bomb calorimeter. The conclusions of the authors are that the average heating power of the eight coals was decreased about 2%, according to calculations from Dulong's formula, and that of the three coals about 0.5%, according to the calorimeter. The results obtained from the curve indicated an average increase of 1%. A summary of the results is given below:

	B. T. U.		
	Heating value per lb. combustible, unweathered.	Decreased by weathering	
Name of coal.		Calculated.	By calorimeter.
George's Creek, Md........	15,989	427	90
New River, W. Va.........	15,913	208	..
Portland, O. (C)...........	15,403	611	160
Portland, O. (B)...........	14,406	341	..
McDonald, Pa. (K)........	14,622	Inc. 63	..
McDonald, Pa. (O).........	15,231	220	40
Pittsburg, Pa.	15,003	95	..
Pittsburg, Pa.	15,353	93	..
Average	15,240	241	97

The heating values of the coals given above are calculated by the Dulong formula from the ultimate analyses. The heating values of three of the coals were determined by a bomb calorimeter, with results as follows: George's Creek, 16,048; Portland, O. (C), 15,461; McDonald, Pa. (O), 15,240. These figures show a remarkably close agreement to the figures calculated from the analyses. In the case of the weathered coals, however, the calorimetric results were occasionally quite different from and always higher than the calculated figures, as is indicated by the figures in the last column. The Portland coal (C) after weathering had a heating value, according to the analysis, of 14,792 B. T. U.; while the calorimeter gave 15,301, a difference of 509 B. T. U., or over 3%.

The next paper was by Mr. William H. Bryan, of St. Louis, entitled

"The Mechanical Plant of a Modern Building."

It was a very elaborate description of the method pursued by Mr. Bryan in planning the installation of boilers, engines, dynamos, elevators, heating, lighting and ventilating apparatus, etc., of a large retail store building in St. Louis, with a description of the apparatus finally installed, the reasons for its adoption, its cost, etc. We shall give an abstract of this very valuable paper in an early issue. A long discussion followed the presentation of the paper, which was participated in by Messrs. George Hill, R. P. Bolton and others who have done work of the same character as that described in the paper. Some of the details of Mr. Bryan's specifications were objected to, and doubt was expressed as to the sufficiency of the heating system in the coldest weather. The plan of asking contractors to bid on two or three alternate kinds of apparatus was criticised, and it was said that the architect and consulting engineer should make up their minds exactly what kind and size of apparatus they want before asking for bids. The discussion showed that a wide difference of opinion exists among engineers who make plans and specifications for the mechanical appliances in large buildings, and the paper, with the discussion, when printed, will be full of interest to such engineers.

The next paper was by Prof. R. C. Carpenter, of Cornell University, entitled "Experiments on the Flow of Steam Through Pipes." The object of the experiments was to determine the coefficient of friction of steam flowing at different velocities through pipes and fittings. The author accepts the formula of Unwin, showing that the coefficient f varies with the diameter and that for a velocity of 100 ft. per second it may be expressed by the formula

$$f = K\left[1 + \frac{3}{10}\,d\right],$$

in which d is the diameter of the pipe in feet and K is a coefficient to be found by experiment. Prof. Carpenter's experiments were made on a pipe 90 ft. long and 2 ins. diameter, and he obtained values of K varying from 0.00093 to 0.00360, which would indicate either that K is not a constant, or that there were large errors of observation, but he takes an average value of 0.0027, and constructs from it a series of tables giving the flow of steam in different diameters and lengths of pipes. The paper was severely criticised in discussion, on account of its drawing conclusions from too few data. Prof. Jacobus gave an account of experiments on flow of steam in pipes of different diameters and lengths, made by Prof. Ledoux, in France, some years ago, and published in the "Annales des Mines," and promised to contribute it to the discussion to be printed in the Transactions.

The last paper of the meeting was read by Mr. Chas. L. Newcomb, on "Experiments on the Flow of Streams from Fire Hydrants." This paper had not been printed in advance, and was read from manuscript. It describes an extensive series of experiments, and gives the curves plotted from the results. It will no doubt prove to be an important contribution to the subject, when printed. The paper was discussed by Mr. John R. Freeman, who is well known as an authority on the subject.

This was the last of the regular papers. Several "queries" that had been printed in the programme of the meeting were then brought up for discussion, as follows:

(1) Does it pay to pickle ordinary castings? The replies were to the effect that it depends on the kind of castings. It rarely pays to pickle a heavy casting, but small pieces, such as hardware castings, may be pickled to advantage. The use of hydrofluoric acid as a very effective pickle was mentioned, and the sand blast was commended as far superior to pickling.

(2) Has any improvement in foundry practice been observed from the recent investigations into the physics of cast iron? No one had any reply to make to this question.

(3) What is the strength of pipe fittings made by a casting process? It was explained that this query arose from trouble experienced by, exporters of pipe and pipe fittings to foreign markets. The fittings in this country are usually of cast iron, and they are objected to by foreign purchasers, since the foreign practice is to make them of wrought iron. No definite answer was given to the query, but it was stated that cast-iron fittings are strong enough for all purposes except that of withstanding water ram in large pipes, and that no fitting will resist.

(5) What constitutes a seamless tube? This question arose from some makers of a tube which is not seamless giving their product the name "seamless." A seamless tube was defined as one which had no line of union, and which never had two portions or edges brought together which were at any time separated since the metal was an ingot. A tube made by cupping and drawing from a sheet, or drawn from an ingot which had a hole cast or bored in it was properly called seamless.

(6) On how small a tool does it pay to put an individual electric motor? The question being taken to relate to machine shop tools, it was replied that it generally does not pay to have any electric motor in the shop of less than 5 HP. Smaller units are apt to give trouble, as they are too delicate an instrument for an ordinary shop. The best plan for small tools is to drive the line shafts by motors, and belts from these shafts to the tools.

(7) Have you any new notions on machine shop floors? Several members discussed this question, not claiming to have "new notions," but relating their experience with floors of various kinds. Spruce floors 3 ins. thick, overlaid with 1¼ ins. of hard rock maple, were commended as being about the most durable floor that can be made.

(8) Is it of real advantage to submerge the smoke-box of an upright boiler, to prevent expansion of the tubes? No answer was made to this question.

These queries were the concluding business of the session. The retiring president, Mr. Hunt, after a few remarks, handed the gavel to the newly elected president, Chief Engineer Melville, who made a brief address, and the meeting was then adjourned. The members and guests registered as in attendance at this meeting numbered 493, over a hundred less than were present at the last annual meeting, but the decrease in attendance was easily accounted for by the severe snowstorms which had prevailed throughout New England and New York state, blockading the railways and making travel unpleasant. The next meeting, in May, 1899, will be held in Washington, D. C.

THREE PARSONS STEAM TURBINES of 500 HP. each are about to be built by the Westinghouse Machine Co., East Pittsburg, Pa., for the Westinghouse Air Brake Co., Wilmerding, Pa., to replace ordinary steam engines. Each turbine will drive a 300 K-W. generator, furnishing current for electric lighting and for driving the Tesla motors used in the Air Brake Co.'s shops. The Machine Co. is also building a 2,500 HP. turbine for the United Electric Light & Power Co., of New York city, the first of an order of five of the same size. These will be the largest steam turbines ever constructed. They are to be installed in the new station at 28th St. and East River. Each turbine will be used to drive a 1,500 K-W. multiphase generator. The five engines and generators, aggregating 12,500 HP. can be placed in about half the space now occupied by eight vertical Westinghouse engines of 1,200 HP. each, each with Westinghouse generators, now in the 28th St. station. The Parsons turbine has been used in England for several years, giving excellent results as to economy. One of the advantages it offers is that the water of condensation may be safely returned to the boiler, as no oil is used in the engine.

◆

A COMBINATION TO CONTROL ELECTRICAL plants in the city of New York is reported as formed, with Wm. C. Whitney, R. P. Flower, P. O. B. Widener, W. L. Elkins and A. N. Brady as members. This trust is in reality the New York Gas and Electric Light, Heat and Power Co., incorporated at Albany early in October with $25,000,000 capital. Mr. John D. Crimmins is the authority for saying that this company has already secured the Mount Morris Electric Co., with independent subways and a franchise for lighting the entire island of Manhattan; the Manhattan and the Edison Electric Illuminating Cos. The only important company outside is the Westinghouse Electric Co., with its franchise for furnishing heat, light and power. The Empire Subway Co., principally owned by the Bell Telephone Co., has also been secured, But the real extent of the operations of Mr. Whitney and his associates, and their ultimate purpose, are as yet practically unknown, as Mr. Crimmins is no longer associated with the deal, and Mr. Whitney insists that the details are exaggerated, and the Metropolitan Traction Co. simply seeks to sell its surplus power. The purchase of the Manhattan and Edison companies is not confirmed.

◆

THE EXTENSION OF STREET RAILWAY FRANchises in Chicago for a period of 50 years is asked for by the Chicago street railway companies, and an ordinance extending all their franchises for that period has been presented to the City Council by representatives of the leading companies. It provides for payment to the city of a certain percentage of the gross receipts, to be based upon the earnings per mile, as follows: 0.5% for lines earning $7,500 to $10,000 per mile; 1% up to $12,500, 1½% to $15,000, 2% to $20,000, and 3% for all above $20,000 per mile. It also provides means for ascertaining the amounts of the earnings, sets the time for payment, and establishes a 5 ct. fare during the first 20 years of the extended franchise. The mayor is opposed to the ordinance, considering 50 years too long a term, and that the franchises should only be extended for 20 years. He also favors higher rates of compensation, and requirements for improved service on the part of the companies. A mass-meeting was held on Dec. 11 to protest against the extension of the franchises, and the municipal ownership of the street railway lines was favored. On the following day it is reported that the council "indefinitely sidetracked" the ordinances by a vote of 38 to 25.

◆

A CONTRACT FOR A NEW WATER SUPPLY for Jersey City has been awarded by the Street and Water Commissioners to Mr. Patrick H. Flynn, of 189 Montague St., Brooklyn. It is expected that the Board of Finance and the Mayor will approve the award. Mr. Flynn is to build works for the delivery of water by gravity to the present distribution system, the city to buy water by the million gallons, unless it decides to purchase the works. The latter plan it cannot adopt for the present, owing to its financial condition. The supply will be from the Rockaway River. The price per million gallons will be as follows: For the first 25,000,000 gallons a day, $36; for the next two 5,000,000 gallons, $34 and $32, respectively; for the next 10,000,000 gallons, $24; for all above 45,000,000 gallons per day, up to the limit of the possible capacity of the works, or 70,000,000 gallons, $20. This is on an average of $31.40 per 1,000,000 gallons for 50,000,000 gallons a day, and of $28 for 70,000,000 gallons a day. In case the city elects to buy the works, the price for a plant developed to a capacity of 50,000,000 gallons a day, but with a drainage area able to supply 70,000,000 gallons, would be $7,595,000, if the works were bought at completion, and $7,995,000 if bought at the end of 5, 10 or 15 years after completion. Works developed to supply 70,000,000 gallons a day would cost the city $8,745,000, or $9,245,000, respectively, in accordance with the dates of purchase mentioned above. It is reported that Mr. Flynn has made arrangements with the East Jersey Water Co., and those associated with it, for the necessary water rights in the Rockaway drainage area.

◆

A COMBINATION ARCH AND GRAVITY MASONRY dam is being built near Johannesburg, South Africa, with Mr. Wm. Ham. Hall, M. Am. Soc. C. E., of San Francisco, as consulting engineer. The extreme height of the structure, from the foundation to the crest, is about 120 ft., and the maximum depth of water will be about 90 ft. The arched portion of the dam will be 340 ft. long, with a radius of 275 at the crest. The thickness of the arched portion will be 36¼ ft. at the top of the foundation, with an offset of 3½ ft. 20 ft. above, and a batter to 7 ft. at a point just below the coping. The valley at the dam site is some 600 ft. across. The foundation will be of concrete and old rails, and the superstructure of uncoursed rubble. A Lidgerwood cableway is used for constructing the dam. The water impounded by the dam will be used for mining purposes. The work is being carried out by the Vierfontein Water Syndicate, which is controlled by the Consolidated Gold Fields, Messrs. H. Eckstein and others.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred Dec. 7 on the Clarion River R. R., near Portland Mills, Pa., resulting in the death of three persons and in the injury of three others. A freight train was cut in two to descend a steep grade, and while the first section was descending the rear section started down the grade and ran into the first section, killing a brakeman. An engine and crew of five men was ordered out to clear the track. On the return trip it jumped the track, rolled down an embankment, and so seriously injured two men that they died within a few minutes.

◆

THE FALL OF A THEATRE ROOF in Detroit, Mich., on Nov. 5, mentioned in Engineering News of Nov. 10, resulting in the death of 12 persons, was due, according to the verdict of the Coroner's jury

> to the collapse of the trusses of roof of said building, caused by said trusses and steel roof construction not being of sufficient strength for the weight they were carrying. We find that the responsibility for said collapse rests upon the firm of John Scott & Co., architects of said building.

◆

THE FALL OF A SECTION OF STEAM PIPE in the United States Electric Lighting Co.'s power station in Washington, D. C., on the night of Dec. 8, caused the extinguishment of every light operated by the station. According to press reports, one of the steam pipes burst and a large section of the pipe fell striking a corner of the switchboard in such a way that all of the station lights were extinguished. To properly repair the damage it was necessary to cut off all the circuits.

◆

THE U. S. BATTLESHIP "MASSACHUSETTS," on leaving the Brooklyn Navy Yard on Dec. 11, struck on a sunken obstruction near Diamond Reef, and sprung a leak in several of her forward compartments. The leaks were quickly stopped by cement, and she will be put into the dock at the yard for permanent repairs. The divers report later that the keel is twisted and buckled at 17 places over a length of 240 ft.

A LARGE GAS HOLDER WAS WRECKED at Baltimore, in a high wind on Dec. 4. The tank, which is one of a row, was partially overthrown against the stone coping containing its water bed. The weight crushed the supporting columns on the leeward side of the tank breaking each into several pieces. The contact with the edge of the coping tore several rents in the shell of the tank, and it is supposed that sparks caused by the friction of the metal against the stone ignited the gas, which escaped through these holes. The contents, amounting to about 300,000 cu. ft., caught fire a few seconds after the gas began to escape, and the portion already in the air exploded, bending the top and sides of the tank. The heat of the flames warped and blistered the metal on the outside for a distance of about 75 ft. The reservoir was 97 ft. in diameter, 47 ft. high, and supported by eight columns of ¾-in. cast iron internally fastened by flanges, reinforced by columns of lattice work. The tank had been in use for 28 years.

◆

THE FAILURE OF A LARGE GAS TANK belonging to the Consolidated Gas Co., of New York, N. Y., and located on the block bounded by 1st Ave., Ave. A, 20th St. and 21st St., in that city, occurred on the evening of Dec. 13, killing and injuring a number of people and destroying considerable surrounding property. According to the best available information the tank, which had just been completed, was being tested when the failure occurred. The holder was 174 ft. in diameter, made up of four sections which telescoped into each other, and which, when fully extended, brought the top of the holder 160 ft. above the bottom of the retaining tank. The retaining tank was 178 ft. in diameter and was a steel cylinder extending 17 ft. below the surface of the ground and 25 ft. above the surface. The retaining tank altogether was thus 42 ft. deep, and it was built of steel plates decreasing in thickness from 1½ ins. at the bottom to 1 in. at the top. To stiffen the tank there were a row of metal buttresses around its outer circumference and a circular lattice girder at the top. There were the usual lattice column girders, pulleys, counterweights, etc., for raising and lowering the holder. The tank and holder were complete, except for minor details, and, as stated above, were being tested preparatory to putting them into use. In order to make the test it was necessary first to fill the containing tank with water and then pump air into the holder until it rose section by section to its full height. According to the best reports of the failure which are available the containing tank was just filled with water when the accident happened. An examination of the ruins shows the shell of the retaining tank torn open vertically in several places, but on the north side the rupture was complete and the ruins of the holder had been thrown or carried through the break and were piled high across 21st St. The failure resulted in the gas being shut off from all consumers supplied by the plant of which the destroyed tank was to have formed a part. Among those who suffered most inconvenience from the shutting off of the gas were the number of daily papers and printing offices which used the gas to heat the type metal used in their linotype machines. The office in which type for Engineering News is set was among the sufferers, which accounts for the delay which some of its subscribers may experience in receiving their copies of this issue. A more complete description of the accident will be given in these columns next week.

◆

BREAKS IN WATER MAINS at Philadelphia and at St. Louis are reported as having occurred within the past few days. The mains in each case were 36 ins. in diameter.

◆

A BREAK IN A 48-IN. WATER MAIN occurred early Sunday morning, Dec. 11, in the eastern part of Brooklyn. A hole some 50 to 75 ft. square and 15 ft. deep was washed out by the escaping water; several buildings were undermined, numerous cellars were flooded, sidewalks and streets were damaged, and sand was deposited here, there and everywhere. A section of a small egg-shaped sewer, and of a pipe sewer, as well as gas mains and small water mains, were washed out, and the double track of the electric railway in the street was left without visible means of support for a hundred feet. The broken pipe was one length of a 48-in. supplementary force main laid from the Ridgewood pumping station about seven years ago. It is said that it was under from 30 to 40 lbs. pressure. The break is attributed to a defective casting.

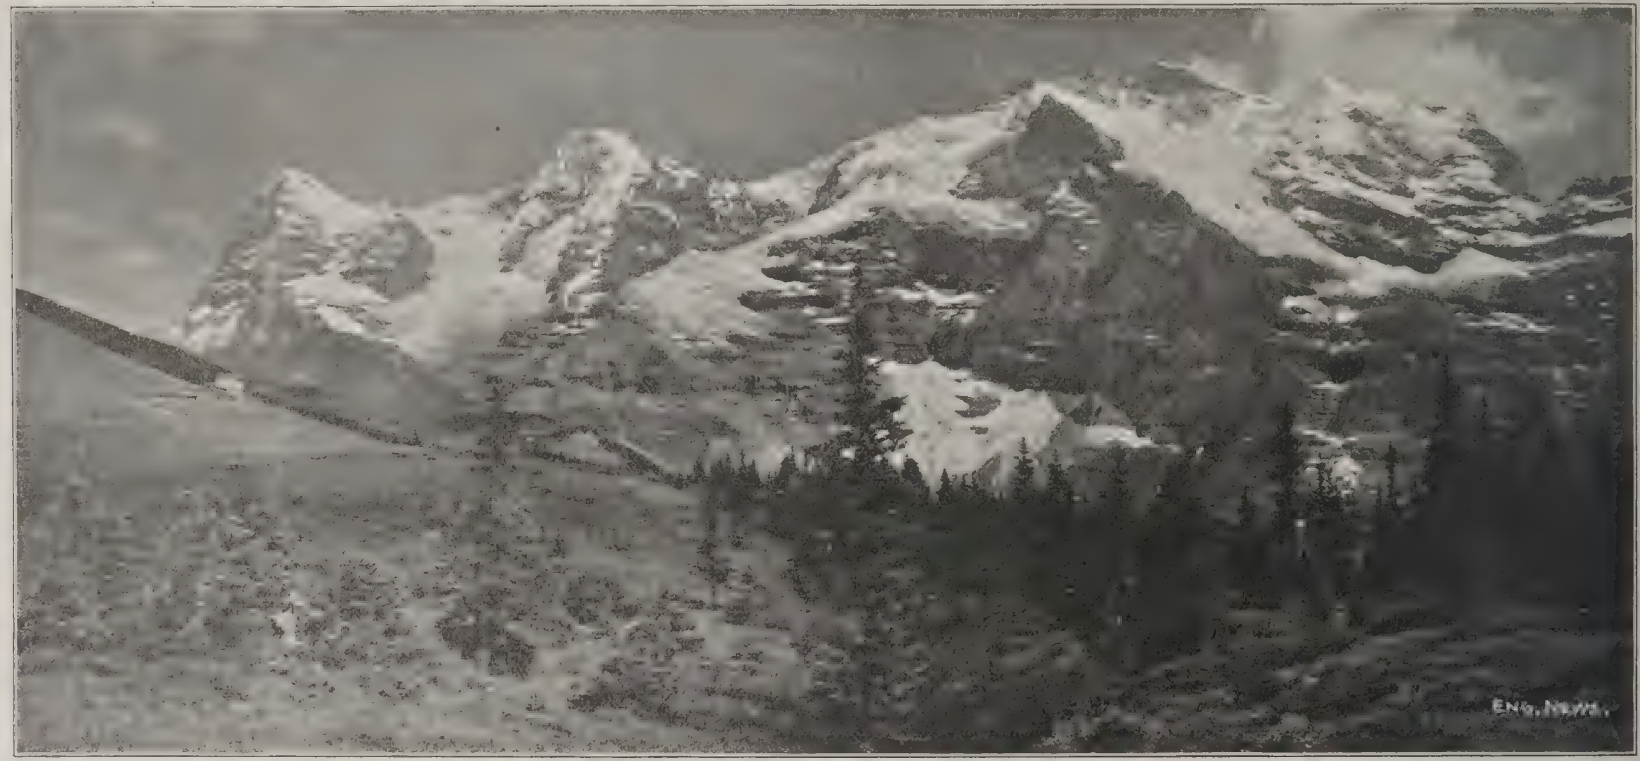
◆

A 6,000,000-GALLON MECHANICAL FILTER PLANT, at Norfolk, Va., is to be built by the New York Filter Mfg. Co., of New York city. The contract was recently awarded the company at $55,000. Mr. J. Thomas Peele is registrar of the Norfolk water-works. At Holyoke, Mass., Mr. James L. Tighe, Engineer of the water-works, has been instructed by the water commissioners to prepare plans for slow sand filtration of the water from the Whiting St. reservoir, which furnishes about one-third of the supply of the city. The estimated cost of the filter beds is $25,000. Mr. Tighe thinks work will be started next April. At West Superior, Wis., the water company is investigating filtration, and has consulted with Mr. Allen Hazen, M. Am. Soc. C. E., of New York city. Mr. W. H. Winslow is secretary of the company.

THE JUNGFRAU ELECTRIC RAILWAY.*

Swiss mountain railways are in a general way so well known that the suggestion of a description of another is apt to arouse little interest. However, the mountain road now being constructed into the very heart of the "Jungfrau" of Switzerland cannot fail to interest, owing to the novelty and boldness of the scheme.

The Jungfrau is one of the highest of the Swiss Alps, and is the highest of the group of three neighboring peaks, Eiger, Moench and Jungfrau. Its snow-capped summit, standing 13,670 ft. above the sea level, affords a magnificent view of the impressive mountain scenery, and has ever been a favorite climb among those sturdy enough to scale its rugged sides. The illustration, Fig. 1 affords an excellent idea of the grandeur and sublime beauty of this mountain mass.



Eiger. Moench. Jungfrau.

FIG. 1.—VIEW OF THE JUNGFRAU GROUP, FROM A PHOTOGRAPH TAKEN NEAR LITTLE SCHEIDEGG STATION.

To make accessible to all visitors the magnificent panorama of snow-capped mountains and glistening glaciers which has heretofore been only possible to hardy mountain climbers, is the project which is now being carried into effect through the untiring energy of Herr Guyer Zeller, president of the Jungfrau Railway Commission It is, of course, out of the question to build a railway on the surface of the mountain, which is one succession of high precipices and deep ravines, and where avalanches occur almost daily at certain seasons of the year. The idea, from the inception of the scheme, has been to tunnel the mountain not far below its surface, and finally reach a point at the base of the highest peak, from which point a vertical shaft would run straight up to the summit, which is about 7,000 ft. above Little Scheidegg, at the base of the mountain, where the mountain railway will begin. This station, nestling at the foot of the great Eiger peak, is on the Wengern Alps Ry., a rack railway, which, by means of a powerful steam locomotive, climbs up from Lauterbrunnen, 4½ miles distant, to the crest of the lower ridge, which is capped by Little Scheidegg (A, Fig. 2), with an elevation of 6,670 ft. above sea level, and then descends on the other side to Grindelwald. The new road, as already mentioned, starts from this station, and, after climbing along the base of the Eiger for a distance of 1.2 miles on a 10% grade, rapidly increasing to 20%, until it reaches the Eiger Glacier station (B), 840 ft. above the starting point. It then plunges into the hard rock of the mountain, through which it burrows for 0.9 mile on a 25% grade to the second station, Eiger Wand (C), 9,200 ft. above sea level. Here the tunnels runs close enough to the face of a precipice to permit windows to be cut through. Continuing the road climbs up still on a 25% grade, and in tunnel until it emerges into the open air at Eismeer Station (D), 1.5 miles further on and 10,360 ft. above sea level. The next section is on a 6¼% gradient, and up this the tunnel continues the climb for 2.6 miles to Jungfraujoch, (E) the fourth station, 850 ft. above the last, and 11,210 ft. above the sea. From this station, for a distance of 1.7 miles, there is a steady ascent on a 25% gradient to the foot of the elevator shaft (F), 240 ft. below the highest point of the Jungfrau. At the top of the elevator shaft will be erected a suitable sheltered observatory provided with everything necessary for the comfort of visitors. Table I. gives in a compact form the distances and elevations of stations and the various grades.

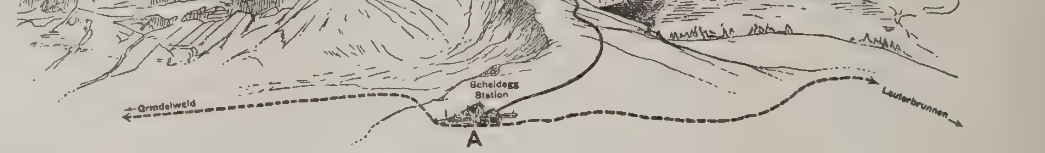


FIG. 2.—SKETCH OF THE JUNGFRAU GROUP, SHOWING ROUTE OF TUNNEL AND LOCATION OF STATIONS.

TABLE I.—Distance Between Stations, Elevations, and Gradients of the Jungfrau Railway.

No.	Station.	Height, ft. Station to station.	Height, ft. Above sea level.	Distance, miles Statn to station.	Distance, miles From start.	Maximum gradient, %.
A	Little Scheidegg...	0	6,770	0	0	0
B	Eiger Glacier	840	7,610	1.2	1.2	25
C	Eiger Wand	1,610	9,220	0.9	2.1	25
D	Eismeer	1,140	10,360	1.5	3.6	25
E	Jungfraujoch	850	11,210	2.6	6.2	6¼
F	Elevator	2,220	13,430	1.7	7 9	25
	Summit Jungfrau...	240	13,670	...	7.9	vert.

With the exception of the Jungfraujoch, the stations will be enlargements of the tunnel in the solid rock, affording visitors an opportunity to look out over the mountain scenery only from windows and balconies cut through the rock faces. It is expected that Jungfraujoch will be a point of departure for sledging or pedestrian parties. The subterranean stations will be equipped with hotel conveniences so that passengers desiring to, may stop off for a short rest or all night if desired. About three-quarters of the total distance, some 6.7 miles, must be cut through a firm limestone, which, if dependence can be placed upon the smooth, firm exposed slopes, which show no disintegration, will need no lining. The remainder will be in alternate layers of gneiss and limestone, requiring a masonry lining. It is the intention of the engineers to line this section with the rock blasted in tunneling, laid in Portland cement. This cement they expect to work at temperatures as low as — 6° C (+ 21.2°F.). The water for mixing will be carried into the tunnel in the form of ice, which will be melted when needed by electric heaters, and kept in a liquid form by the addition of a small quantity of salt. The tunnel is 14 sq. meters (150.6 sq. ft.) in section, and in its construction a new explosive compound, "Lithotrit," is employed, because it is free from noxious gases and is not affected by cold. Dynamite is, however, used in open work, and for such work is thawed out by electric heaters and wrapped in non-conducting materials previous to inserting in the drill holes.

---

*Abstracted from the "Electrician" (London), for Sept. 23, 1898, with additional information from "Centralblatt der Bauverwaltung," for Oct. 30, 1897.

At the present time about 1,500 ft. out of the total of some 45,000 ft. have been excavated, and tunneling is progressing steadily, the intention being to continue summer and winter until completion, the time for which is set at 1904. The workmen, mostly Italian laborers, are housed in barracks built on the mountain side. All the drilling, lighting and hauling is done by electricity and a considerable plant is required to furnish the necessary current. Two types of electric drills are being used, a rotary, manufactured by the Oerlikon Co., which is operated by a 3 HP. motor and feeds 0.08 ins. per revolution of the cutter, and the usual percussion form, built by the Union Elektricitats Gesellshaft, making 400 4¾-in. strokes per minute.

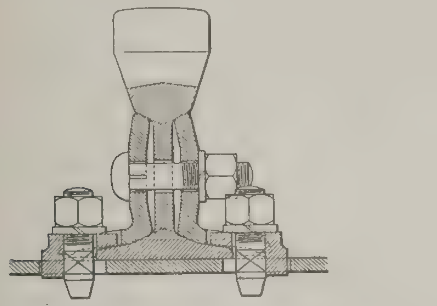

Fig. 3.—Section of the Rack Rail, Showing Method of Splicing and Securing Rack to Ties.

The temporary power plant furnishing current for construction work is located at Lauterbrunnen, where ample water power to drive a 1,000 HP. generator is obtained from the White Lutschine River. This generator, manufactured by the Oerlikon Co., furnishes three-phase current at 7,000 volts with a periodicity of 38 for transmission up the valley to Little Scheidegg and the Eiger Glacier, where the voltage is dropped by means of static transformers to the working pressure of 500 volts. The transmission line is 4½ miles long, in which distance it ascends 4,250 ft. It is composed of 3 bare hard-drawn copper conductors 7.5 mm. in diameter, supported upon large earthenware triple-petticoat insulators 4½ ins. in diameter and about 7 ins. high. Heavy wooden poles 33 ft. long are frequently placed and upon these are mounted galvanized iron brackets. As a precaution, wherever the lines cross footpaths a circular guard net is suspended, almost surrounding the transmission wires. A telephone circuit is also mounted upon the same poles and the conductors of this circuit have to be crossed frequently to counteract the great inductive effect of the high tension current on the transmission circuit.

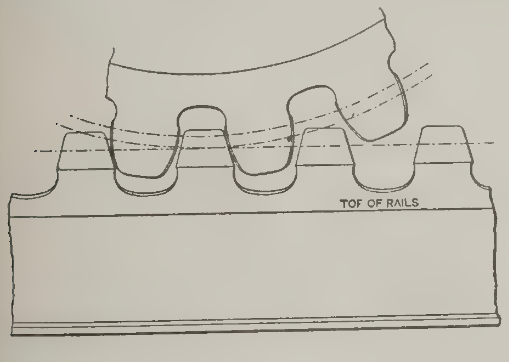

Fig. 4.—Form of Teeth of Rack Rail and Driving Gears.

The substations are substantial stone structures intended to withstand the extremely severe weather of that region, and each contains two 200 K-W. Oerlikon static step down transformers, dropping the current from 7,000 volts to 500, at which voltage it is supplied to the secondary or working feeders. These are 9 mm. hard drawn copper conductors, supported in the same manner as the transmission lines. During construction a rotary converter is employed to supply direct current for rock drills and other machinery. The intention is to install in suitably protected rooms, spaced about every 3,280 ft., static transformers, which will furnish power for mining as the work progresses, and will eventually feed the line wires from which the locomotives will take current. A separate set of transformers will furnish the current for the elevator running up the vertical shaft.

The permanent power plant at Lauterbrunnen, when completed, will be operated by turbines taking water, as in the present plant, from the White Lutschine River. About 1,320 gallons per minute will be required, under a head of 115 ft., which is brought to the power house from just below the Staubbach Water Falls by a steel pipe line 5 ft. 11 ins. in diameter and 4,500 ft. long. For about half this distance the slope of the pipe is only about 0.3%, and this portion has a thickness of 0.197 ins., each section being 19 ft. 8 ins. long. The remainder of the line has a decided grade and varies in thickness from 0.236 ins. to 0.276 ins. At the junction of the two sections, just mentioned, is inserted an air cushion column, its duty being to relieve water hammer on the pipe.

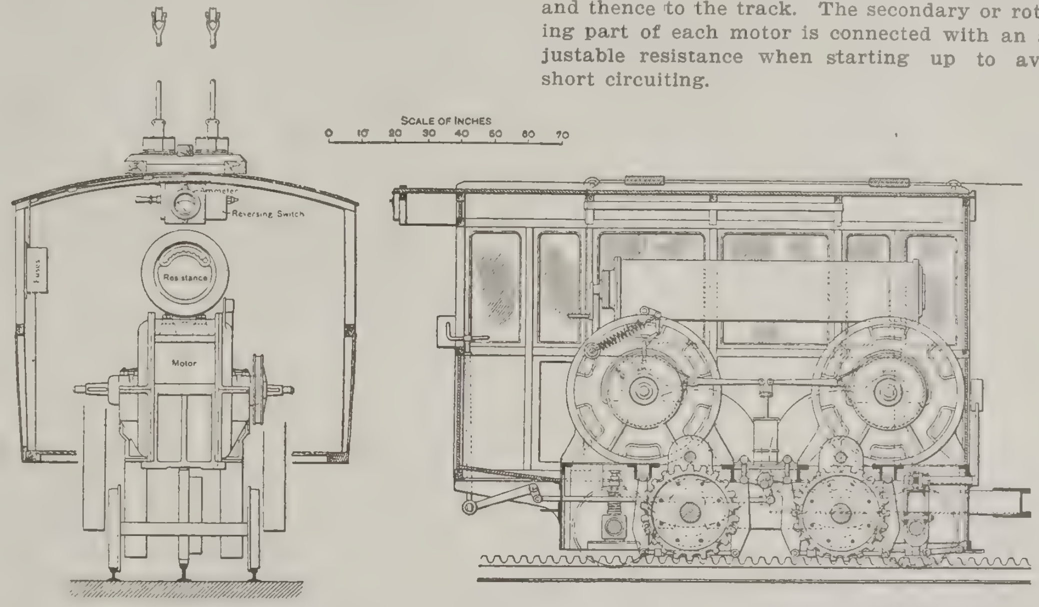

FIG. 5.—ELEVATION AND SECTION OF JUNGFRAU ELECTRIC LOCOMOTIVE, SHOWING TRUCK FRAMING, MOTORS, GEARS AND THE DOUBLE TROLLEY.

The turbines are of the twin Girard type, made by J. J. Rieter & Co. The speed is regulated by Rieter automatic governors belted directly to the turbine shaft. The three-phase generators are manufactured by the Oerlikon Co., and are directly connected to the turbines.

The track and roadbed of the railway will be constructed in the most substantial manner. The rails are laid to a 3 ft. 3⅜-in. gage. They are of the usual Vignoles section and weigh 40 lbs. per yd. Steel channel ties, spaced 3 ft. 3 in. c. to c. are used, and to these are bolted the rack rail, Figs. 3 and 4, which is rolled solid, like the ordinary rail, in lengths of 11½ ft. The teeth are afterwards cut cold. This rail weighs 68½ lbs. per yd. Fig. 3 shows the method of securing the rack to the cross ties and how the sections are spliced. On the road from Eismeer to Jungfraujoch, where the grade is only 6¼%, no rack will be used. On all other sections, however, the rack will be necessary. As the rails are used to carry current, forming one branch of the three-wire system, the tracks are carefully bonded, two "Chicago" copper bonds of 7 mm. section being used for each rail joint, and every 165 ft. the rails are cross bonded with a 8 mm. copper wire.

The trolley wires, two in number, are supported side by side by hanging insulators and span wires strung between wooden poles, on open portions of the line, and by well insulated ceiling hangers inside the tunnel.

The electric locomotives, as will be seen in Fig. 5, consist of a heavy frame built up of channels and I-beams, mounted upon two pairs of wheels, and upon this truck are placed two large three-phase induction motors, which through separate sets of double reduction gears operate the heavy gears meshing into the rack rail. In addition, the whole is covered by a suitable car body to support the four trolley poles, as well as to protect the motors, controller and instruments. These motors range from 125 to 150 brake HP. and run at 760 revolutions per minute on the 500 volt circuit. They weigh 5,200 lbs. each, while the complete locomotive weighs 13 tons.

Fig. 5 shows the arrangement of motors, controller, gearing and braking apparatus of the first locomotive constructed, while Fig. 6 indicates clearly the method of wiring up from trolley to track. For purposes of explanation we may assume that the line current enters the double trolley 1, 2 and 1a, 2a and passes down through a reversing switch and a set of multiple fuses to the stationary part or primary winding of the motors, and thence to the track. The secondary or rotating part of each motor is connected with an adjustable resistance when starting up to avoid short circuiting.

The matter of braking and control of speed is one of considerable importance about which the "Electrician" says:

> One of the great advantages of the three-phase system, aside from cheapness of transmission, lies in the simple automatic breaking action of the induction motor. When the locomotive is going down hill the stator or primary of the motor cannot greatly exceed the speed of synchronism. From Fig. 6 it will be seen that the motors are merely controlled by a reversing switch (through which the stator is connected to the line), and the usual rheostat in the rotor or armature circuit to avoid starting the armature on a short circuit. The locomotive is fitted with three absolutely independent brakes. The first is an automatic one, electrically controlled by means of a centrifugal governor, which, when the speed exceeds a certain maximum, switches the current off the motors, at the same time applying a band brake. A dash-pot prevents slight momentary increases in speed from putting the brake in action. This brake can also be applied by the guard in the passenger car, where a suitable switch is provided. The second brake is a hand one, which applies bronze shoes to a wheel on the driving axle, and the third is an emergency brake, arranged to grip the rack rail. It can be applied by either the engineman or the guard in the passenger car.
>
> The car is pushed ahead of the locomotive and has a capacity for 40 passengers. At times of heavy traffic two cars

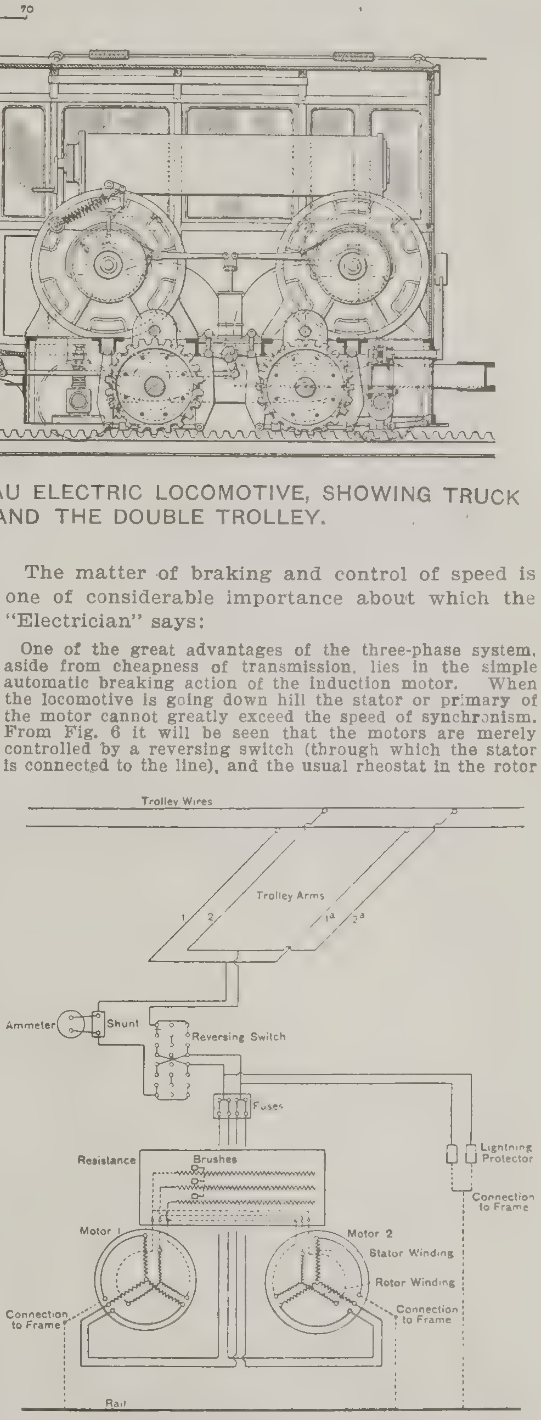

Fig. 6.—Wiring Diagram of the Electric Locomotive, From Trolley to Track.

will be used per train. The train is lighted by 6 incandescent lamps on the locomotive, two in series on each phase, and 15 on each car, arranged five in series on each phase.

The estimates upon which the project was financed allowed a traffic of only 10,000 passengers per year to the top of the Jungfrau, although fully 160,000 persons visited Interlaken in the season of 1895, and the rate of increase of visitors to Interlaken is about 30% every 5 years.

At the time the franchise for the road was given the maximum round trip rate was limited to $8.68; but it is understood that the company contemplates a much lower rate ($6.75), with a schedule for the intermediate stations based upon this.

Using this basis and including the income from all sources, the total annual receipts are placed at about $139,350. The estimated operating expenses, reserve fund and interest on $1,200,000 at 4%, amount to about $86,850. The surplus amount, it will be seen, is equivalent to nearly 7% on $800,000 capital. The entire cost of the road, including construction and equipment, is estimated at $1,930,000.

IMPROVEMENTS OF THE WATER-WORKS OF COUNCIL GROVE, KAN.

By L. L. Tribus,* M. Am. Soc. C. E.

During 1897-8 certain improvements to the waterworks of Council Grove, Kan., have been under the writer's direction. Those not familiar with the action and condition of rivers in alluvial regions, can scarcely appreciate the peculiar difficulties attending their use for public water supply systems. The larger cities of the West have scarcely solved the problem; certainly the smaller ones cannot be expected to have done so.

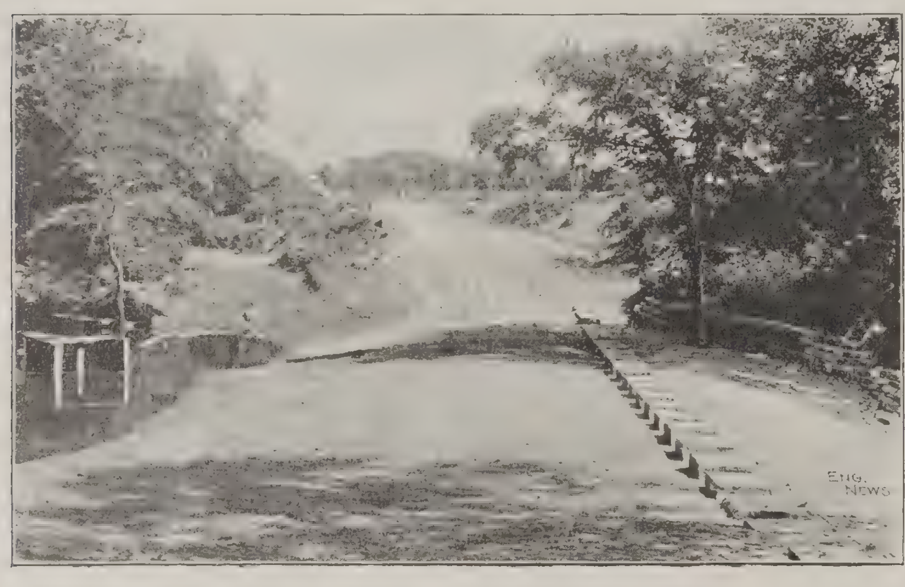

FIG. 1.—HIGHWAY DAM ACROSS THE NEOSHO RIVER FOR THE WATER-WORKS OF COUNCIL GROVE, KAN.
L. L. Tribus, M. Am. Soc. C. E., Consulting Engineer.

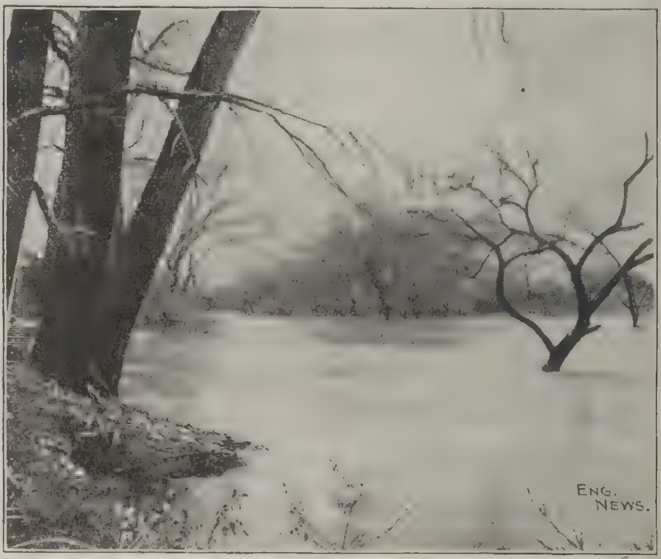

FIG. 2.—COUNCIL GROVE HIGHWAY DAM SUBMERGED BY FLOOD.

The little city of Council Grove, in Central Kansas (under 3,000 population), possesses eminently all the disadvantages of such a source of supply, and is without means to experiment on adequate scale for improvements. The surrounding country consists of rolling prairie land, with a range of elevation of about 100 ft., scantily timbered in spots. The country is intersected at frequent intervals by steep-banked gullies, filled in rainy times by flashy streams, that run from 10 to 30 ft. in depth of water, and a soil of fine blackish loam on limestone or other rock substratum.

The hot winds of summer parch the land; sudden rainstorms, often coming with great violence, wash the powdered soil into the streams, turning them into literally mud rivers; the lack of timber districts to hold back the water and the shallowness of the soil ensures the storm waters reaching the streams in very short order, causing floods of a violence almost unknown in Eastern streams, a rise of 5 to 25 ft. in ten hours being of not infrequent occurrence. Passing between banks of alluvial soil, these floods exercise their own taste in cutting and changing the course of the rivers with little warning or chance for resistance. Deflection cribs are used somewhat, but are of rather problematic value. At the same time these floods are the life of the land; by overflowing the bottoms they deposit much fertilizing material and enable the raising of heavy crops of corn and grain; their abatement being almost as rapid as the rise, relieves the land from "drowning." These general conditions are typical of thousands of square miles of Western lands; eminently so of Council Grove and vicinity.

An engineer would not select the Neosho River, such a one as the above, as the source of supply of a municipal water system unless obliged so to do. The soil is largely clay and loam, and shallow at that. The underlying rock of limestone, not freely water bearing, makes driven or bored wells very scanty in yield of water, usually of very hard quality, unsuited for domestic and manufacturing purposes. No lakes or other sources are available, hence the best had to be made of undesirable conditions.

The city of Council Grove has the same early history of most such prairie towns, built without special reason or necessity, but it is there, and has passed through the throes of municipal development to a stage of permanence and moderate prosperity. Some ten years or so ago, a contract was made on the franchise plan with a private company, for the construction and maintenance of a public water system, directing the company to adopt the Neosho River, as the source of supply. A large brick intake well in the river bank was built, with influent pipe from a deep pool in the river's bed. From this well, the pumps, placed in a neat little brick station, situated some 100 ft. back on higher ground, lifted the water and delivered it at a wrought-iron stand-pipe 20 ft. in diameter by 75 ft. in height, on an eminence nearby, from whence by gravity the city was supplied.

For the period until July, 1897, such water as was used consisted of fairly soft river water, mixed with varying proportions of silt, ranging from a light semi-transparent brown to a deep chocolate color. No special effort was made by the company to improve the condition of the water nor was objection raised by the citizens to its use. Street flushing and sprinkling, boiler use and fire service, naturally made up most of the consumption; rain water tanks and cisterns inadequately serving for domestic needs. In the above month of July, 1897, it began to be realized that modern methods properly adapted could give at least an improvement in supply, and the company, though far from prosperous, undertook to reconstruct the plant, recently completing the changes planned by the writer, its consulting engineer.

A peculiarity of the Neosho River, and one to be remembered, is, that during most of the year it is simply a succession of pools from one-fourth mile to one mile in length, and from 3 to 10 or 12 ft. in depth. The riffles, or low natural dams separating the pools, are composed of a sort of cemented gravel, quite water-tight. When the pool nearest the pumping station becomes too low, a narrow trench is dug through the next riffle above, and its waters are drawn down for use.

Last autumn (1897) this supply, even, came perilously near to being exhausted, but usually storms have been of sufficient frequency to scour out and fill up the pools with fresh water. At best, however, the water was more or less filled with matter in suspension; some of the time becoming offensive. The consumption was about 100,000 gallons per day on the average, the Missouri Pacific Railroad using about one-half the total for its locomotive boilers.

The plans for improving the water plant as carried out, consisted, first, in raising the riffle below the pumping station about 5 ft., making of it a good highway crossing, though submerged at flood times; both of these conditions are shown by the views, Figs. 1 and 2, respectively. This gives additional storage of some 5,000,000 or 6,000,000 gallons, giving opportunity for greater sedimentation, thus improving the quality, or rather decreasing the chance of spoiling, by the increased depth of the reservoir.

A solid masonry dam would have been too expensive, but as rock-bottom was attainable for foundation, a rubble masonry core wall, 5 ft. thick at the base and 3 ft. at the top, was constructed, finished off with a heavy coping, alternate blocks being depressed some 8 ins. to make waterways for the dry weather flow, and the higher stones affording footing for pedestrians. Upstream from this wall was deposited a heavy clay and gravel fill bank, 22 ft. wide on top, with an upstream slope of about 5 to 1. Sixteen feet of the top was paved with stone, edged on the upstream side with a deep-set curve, the downstream side abutting against the core wall. The downstream slope, below the heart wall, was paved with heavy stone blocks, on the same clay and gravel fill of which the rest of the dam was built.

The general idea and hope, based on a study of the river's action, was that floods would pass over in a "roll" without scouring action, the flat slopes and broad crest deflecting rather than checking the current. Events have thus far justified the belief, for a number of floods have already passed over the dam without causing any special damage, and even depositing some additional gravel on the crest.

A 24-in. cast-iron pipe sluice serves for a low water drain when needed. The pool enlarged by this dam extends about 1½ miles upstream to near the foot of an old timber crib dam (also controlled by the Water Co.), which forms a second storage reservoir. At present this is in a very dilapidated condition, but it is the intention to later put it in substantial shape again.

The second main change of system was the installation of a filtration plant. The filter erected by the New York Filter Manufacturing Co. consists of a wrought-iron closed tank, 10 ft. in diameter, filled with sand. gravel, coke and broken stone, housed in a neat brick addition to the pumping station. Water from the pumps is forced through this closed tank into the main to the stand-pipe; a small volume of water under the same pressure passing through a by-pass and small tank filled with lumps of sulphate of alumina, and in turn joining the main volume of water before reaching the filter. Enough of the alum is taken up to form a flocculent precipitate, which assists the upper layers of the sand in entangling and retaining matters that are in suspension.

---

*Consulting Engineer, 84 Warren St., New York.

For ordinary stages of the river, this process yields clear water. For specially muddy stages there is admitted to the suction well some lime water, and just before entering the pumps, a strong alum solution. This, it is hoped will, with a slower rate of filtration, answer for all conditions, though as yet the experiments have not been of sufficient duration to demonstrate to a certainty. The reversal of current in the filter once in one or two hours, for a few minutes at a time, suffices to cleanse the filter, and keep it in good operating condition, without a very large waste of filtered water (used for the washing).

The building added to the pump-house is arranged for two mechanical filters of 250,000 gallons capacity per 24 hours each, though but one is as yet installed. In the pumping station are also situated the city electric lighting engines, operated by the same steam plant that supplies the pumping engines; so the combined operations can be carried on with reasonable economy—pumping by day and running the dynamo at night. With filtered water the economy in operating the boilers is considerably increased, over the former use of rolly water, all that was then available.

It is not claimed by the water company that the results secured make the plant ideal in any way, but that making the best of poor advantages, the improvements can be called successful, and a very unfortunate supply of water made available for fairly satisfactory use.

METHODS OF WORK ON THE ST. LAWRENCE POWER CO.'S WATER POWER CANAL NEAR MASSENA, N.Y.

(With full-page plate.)

One of the most notable pieces of canal work now in progress in this country is that for the new water-power electric plant which is being built at Massena, N. Y. This canal will be 187½ ft. wide on the bottom, which, with a depth of water of 25 ft., and side slopes of 1 on 1½, will make the width at water level 262½ ft. As will be noticed, this section is greater than that of any other existing canal, and will be exceeded only by that of the Chicago Drainage Canal when this is excavated to its final dimensions of 202 ft. wide on the bottom, with a depth of water of 22 ft. and side slopes of 1 on 1½. Fig. 1 shows a cross-section of the St. Lawrence Power Co.'s canal as it is planned, although it seems probable now that some of the material will actually require flatter slopes in order to stand, and, therefore, that some of the figures which have been adopted will be changed for certain sections of the work at least. The drawing shows only the normal section, which is to be widened out at one end to form an entrance bay, and at the other end into a fore bay. The dimensions of these enlargements are not yet finally determined. Altogether the work will entail the excavation of about 8,000,000 cu. yds. of earth consisting mostly of quite soft clay and clayey loam, although in the two deep cuts and at other isolated points a sort of hardpan or very hard indurated clay filled with boulders of all sizes is encountered. In the power house foundation work there is also considerable rock excavation.

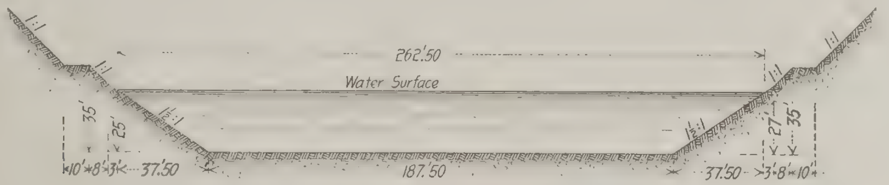

FIG. 1.—CROSS SECTION OF THE ST. LAWRENCE POWER CO.'S WATER POWER CANAL, NEAR MASSENA, N. Y.

The engravings on our full-page plate and in the text show the methods being employed to excavate these materials. These photographs and drawings and the bulk of the information from which this description has been prepared were collected during a visit made to the work on Nov. 17 and 18 by a member of the editorial staff of Engineering News. For aid in collecting this material we are indebted to Mr. Robert Swan and Mr. J. B. Walker, respectively Vice-President and Assistant Engineer of The T. A. Gillespie Co., of New York, the contractors for the work, and to Mr. Wm. H. Cushman, Resident Engineer, St. Lawrence Construction Co., Massena, N. Y. The entire work is being carried on by The T. A. Gillespie Co., and all the plant described is owned and operated by it.

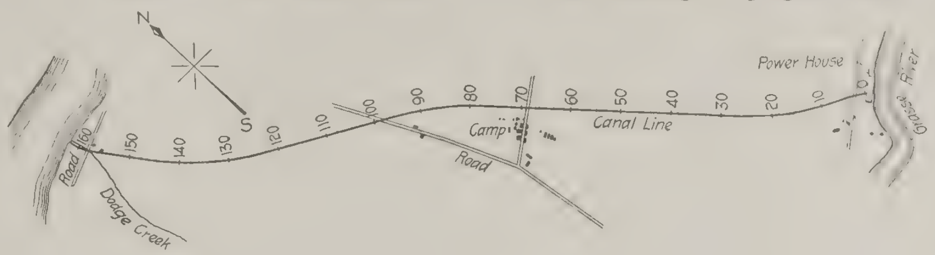

FIG. 2.—MAP SHOWING ROUTE OF ST. LAWRENCE POWER CO.'S WATER POWER CANAL.

Historical and General Description.

The Massena water-power electric plant is being built by the St. Lawrence Power Co., of London, England, and English capital is being very largely employed. The actual work of construction, however, is being done by the St. Lawrence Construction Co., of New York, N Y., which is generally understood to bear the same relation to the St. Lawrence Power Co., as the Cataract Construction Co. did to the Niagara Falls Power Co. Mr. John Bogart, M. Am. Soc. C. E., of New York, is Chief Engineer of the construction company. The St. Lawrence Construction Co. sublet the work first to the Lehigh Construction Co., which began operations in the summer of 1897, and installed considerable plant, a large camp, shops, stables, boarding barracks, etc. No great amount of actual excavation, however, had been done by the company when it assigned on Feb. 15, 1898. Matters which had naturally become somewhat mixed were readjusted, and a new contract was let to The T. A. Gillespie Co., of New York city, on June 15, 1898. This company began work 15 days later, on July 1, and has pushed the excavation rapidly since that time.

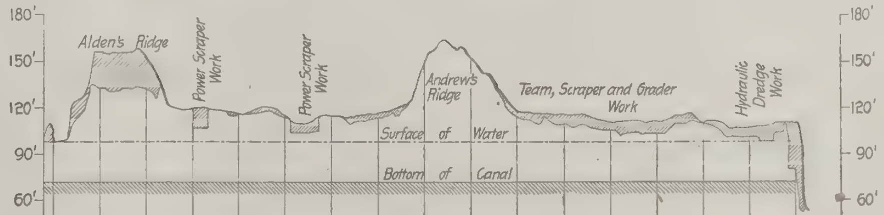

FIG. 3.—PROFILE OF ST. LAWRENCE POWER CO.'S WATER POWER CANAL.
(Shaded area shows progress of excavation on Nov. 1, 1898.)

The plan contemplated is to divert a portion of the waters of the St. Lawrence River and carry it by a surface canal across a comparatively level plateau to the gorge of the Grasse River, where a fall of 42 ft. can be secured. As shown by Fig. 2, the line of the canal is almost straight southeast.

The Grasse River acts as the tail race discharging the water into the St. Lawrence River again, but further downstream. It is just on the bank of the Grasse River that the power house will be situated, which will be almost a duplicate of the power house of the Hudson River Power Co., at Mechanicsville, N. Y. (Eng. News, Sept. 1, 1898), in everything except size, the Massena plant being about three times larger. Fig. 1, as before stated, is a cross section of the canal prism; Fig. 2 is a sketch map of the line, and Fig. 3 is a profile of the canal showing the progress made in excavation up to Nov. 1, 1898. As will be seen, the canal is about 16,200 ft., or slightly over three miles long.

Methods of Excavation.

The general method of excavation adopted is to take out the surface lift and the deep cuts to a depth of about 5 ft. above the water surface by some system of dry excavation. According to the preliminary borings this will remove all of the harder material. The remainder of the prism between 5 ft. above the water surface and the bottom of the canal it is proposed to take out in the wet by dredging. Two dredges will work inland from the St. Lawrence River and another is now working west from the low point A on the plateau just above the power house. The two dredges which will start at the St. Lawrence River end are orange-peel hydraulic dredges of the vacuum pump type. These machines will be described fully in a separate article in a future issue and will not be mentioned further here except to state that at the time of the visit made by our representative they had not begun work.

Hydraulic Dredge.—The hydraulic dredge proper in operation near the power house end of the canal is shown at work in Fig. 4. Those of our readers familiar with the hydraulic dredges operated on the Pacific coast (Eng. News, Aug. 4 and 11, 1892), on the Chicago Drainage Canal (Sept. 6, 1894, July 4, Aug. 15, 1895), and in other places will recognize the essential features of the machine illustrated, which was built by the Morris Machine Works, of Baldwinsville, N. Y., for The J. A. Gillespie Co. Briefly described, the dredge hull is 65 ft. long, 30 ft. wide, and 6 ft. deep. At the front is an A-frame carrying the ladder supporting the cutter and suction pipe, and at the rear are the two spuds on which the dredge swings when at work. Between the spuds and A-frame comes the housing for the machinery.

The dredging pump is one of the Morris Machine Works regular 12-in. high lift centrifugal pumps, directly connected to a 125-HP. compound condensing engine. This pump is designed to operate against a lift of 60 ft., and is very powerful. At a moderate speed of from 150 to 175 revolutions it is stated that a vacuum of from 20 ins. to 25 ins. can be easily maintained on the suction. The pressure on the discharge pipe is usually 18 lbs. running up to 25 lbs. The suction pipe is 12 ins. in diameter and extends to and inside the rotating cutter carried by the ladder. Both the cutter shaft and pipe are coupled so as to allow free movement to the ladder up and down in a vertical plane. The ladder is 45 ft. long. The cutter is basket-shaped, made of flat iron bars, and resembles quite closely that used on the Vivian dredge employed on the Chicago Drainage Canal (Eng. News, Aug. 15, 1895). A 6¼ × 10-in. six-drum hoisting engine is also arranged on the forward end of the dredge, one end being used for raising and lowering the suction ladder, two for swinging the dredge, by means of the guy lines to the opposite banks of the cut, and two for operating the two stern spuds. This engine also generates the cutter. Progress ahead is made by alternately raising and swinging on these spuds, thus "walking" the dredge forward. Steam is supplied by a locomotive boiler of 125-HP. at 125 lbs. pressure. Control over all of this machinery is had by the operator from the operator's house at the front end of the dredge.

At the time of the visit of our representative the dredge was working in blue clay, and water was being pumped from the Grasse River, 1,700 ft. away, to supply the necessary water for floating and operating it. This material runs about 15% solid from the discharge pipe, and the average output of the dredge has been about 1,000 cu. yds. in two ten-hour shifts. Although ordinarily well diluted with water, it has sometimes happened that the material was fed into the pump so rapidly that the 1,000 ft. of discharge pipe leading to the shore has started to clog up, when simply by increasing the speed of the main pumping engine the clay would be forced out through the end of the pipe in a nearly solid mass which would break off in lengths of 15 ins. to 18 ins. and drop down. This phenomenon is, of course, always of short duration. Perhaps the most peculiar feature of the work, however, is the pumping of the water in which the dredge operates from a source 1,700 ft. away. A 12-in. Worthington pump is employed to do this pumping, and so far a 6-in. discharge pipe has supplied all the water wanted, but a 12-in. pipe is provided for use if needed.

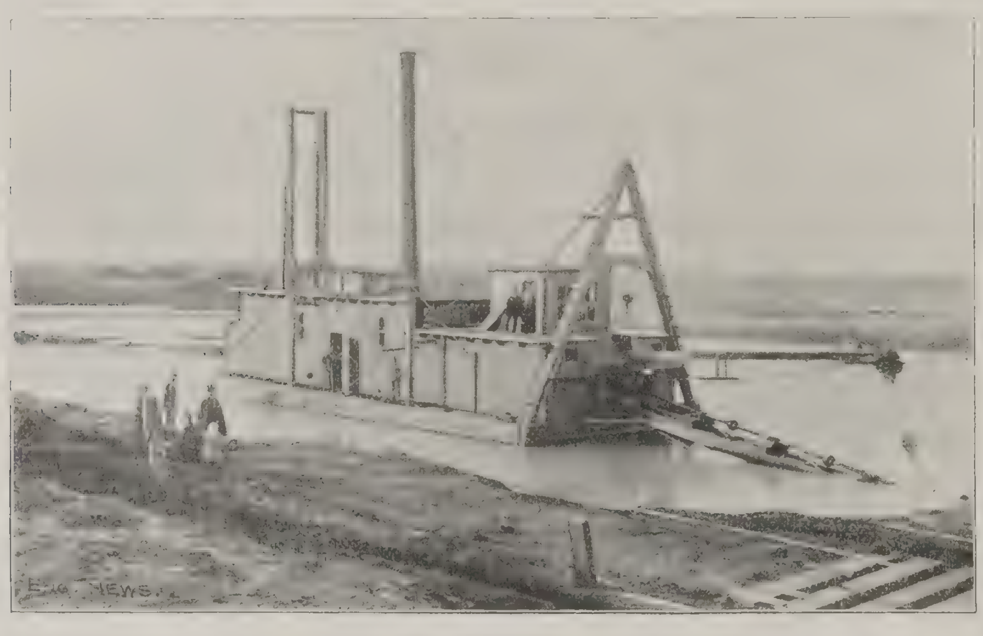

FIG. 4.—HYDRAULIC SUCTION DREDGE WORKING NEAR SOUTH END OF CANAL.

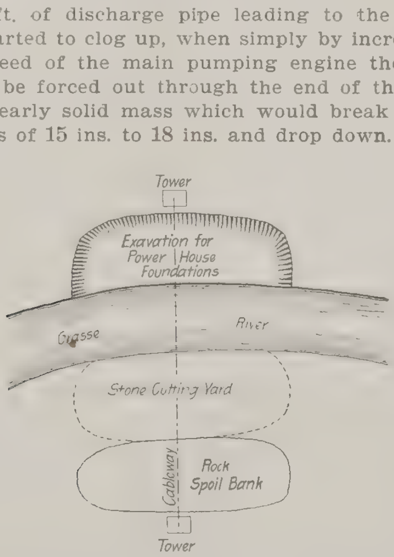

Fig. 7.—Sketch Plan Showing Method of Rock Excavation, Power House Foundations.

The fact that it is regarded justifiable to employ a hydraulic dredge when the water needed for its operation has to be artificially supplied is due in this case to the character of the material. This is a blue clay which is very soft when wet, and which is so located that seepage would be likely always to keep it wet if dry excavation were resorted to. These conditions, unfavorable to dry excavation, are decidedly favorable to successful hydraulic dredge work, which also has here the favoring condition that a neighboring depression affords a convenient discharge basin for the spoil, while allowing the water to drain back to the dredge cut after depositing its load. As stated above, the dredge now handles 50 cu. yds. per hour, and was designed to average 200 cu. yds. per hour. The working crew required consists of the captain, one operator, one engineer, one fireman, and from four to six men to keep the pipe line in order.

Power House Foundations.—The excavation for the power house foundations consists of breaking down the face of the gorge to a level of about 17 ft. below the water level of the Grasse River over an area of about 147 × 633 ft. Figs. 5 and 6 are views of the work, and Fig. 7 is a sketch plan explaining the method of operations. The material is clay down nearly to the water level, and solid rock below, amounting to about 39,000 cu. yds altogether. A steam shovel and a land dredge are the principal machines employed in taking out the soft material, the dredge being worked on the top of the bank, Fig. 5, and the shovel in the cut. Both excavators load into dump cars hauled by locomotives to the spoil banks.

The land dredge, or "orange-peel" excavator, as it is called, is taking out a cut 35 ft. deep in a very homogeneous, cheese-like material. With a 1 cu. yd. bucket the output per ten-hour day averages 600 cu. yds. The total labor cost of operating the machine is stated to be under $20 per day, making it a very cheap and efficient device for handling the material in which it is working.

For the rock excavation a cableway built by the Lidgerwood Mfg. Co., of New York city, is the principal conveying device. As shown by Fig. 7, this cableway spans the excavation, the Grasse River, and a stone yard and spoil bank on the opposite side of the river. Much of the rock being excavated comes out in good enough shape to be used in the foundation masonry, and this is taken across the river by the cableway to the stone cutting yard, where it is cut and stored for future use. The stone in the spoil bank will also be utilized in making concrete, some 30,000 cu. yds. of which will be used in the power house masonry. The view, Fig. 6, shows clearly the condition of work on the power house excavation on Oct. 3, 1898. The Grasse River is shown at the right, or looking down stream, and the line of the cableway may also be seen. This cableway has a span of 1,130 ft.

Team, Scraper and Grader Work.—From the hydraulic dredge work north to Andrews Ridge the top 5 ft. to 8 ft. of loam and clay has been removed by wheel scrapers, power graders and teams. Both the New Era and Western graders have been employed, and their output per ten-hour day has averaged from 600 to 800 cu. yds. Figs. 8 and 9 are views of the scraper and grader work, and they show quite well the nature of the material being handled. Similar methods of excavation were employed north of Andrews Ridge.

Power-Scraper Work.—One of the most notable excavators used on the work is the power scraper designed by Mr. Charles Vivian, and first employed by him on Section 6 of the Chicago Drainage Canal (Eng. News, Aug. 15, 1895). This device showed evidence of its value on the Drainage Canal work, although by the time it had been perfected most of the material in which it was capable of working had been taken out. Its output averaged from 24 to 24½ cu. yds. per hour. Much better work than this has been done by the scrapers on the Massena canal work, they having averaged about 800 cu. yds. per ten-hour day, according to a statement made by the contractors. Figs. 10, 11 and 12 explain pretty clearly the operation and work of the scrapers.

Fig. 10 is a diagram explaining the operation of the scraper. As will be seen, it has three cables attached to it; cable A is used to tip the scraper on end; cable B draws it backward into the pit, and cable C hauls it out of the pit when filled. The method of working then is as follows: When the scraper has been drawn into the pit and is in the position shown by Fig. 10, cable A is hauled in sufficiently to stand the scraper on its end, as shown by Fig. 10a. Cable C is then hauled in and the scraper fills as it resumes its original position, and is then hauled out of the pit onto the spoil bank. When here cable A turns the scraper over and drags it a few feet to empty it, after which cable B turns it right side up and drags it back into the pit.

The material in which the scrapers are working is a clayey loam turning into clay toward the bottom of the cut. Fig. 11 shows its nature quite clearly, and also shows the sequence of cuts made as the scraper advances. The ridge of earth left between cuts serves two purposes. First and most important, it permits the scraper to form a path or groove which aids to keep the scraper in line and facilitates its loading; second, when there is much water, as shown in the illustration, it acts as a natural dam to keep the water of one cut from flowing quickly into the succeeding cut. Ultimately, of course, these ridges are broken down and taken out. The scraper, while requiring soft material for its most perfect operation, has its efficiency greatly reduced by the presence of water, which is the reason for keeping the cut as dry as practicable.

Fig. 12 shows the scraper proper with its load; this load of top soil having been taken out in the course of ordinary operation, but being, of course, considerably larger than the general run. The scraper proper, as the illustration shows, is made of steel plate. Its capacity is 3 cu. yds. water measure, and it has a 7-ft. cutting edge. It is planned to lengthen the scraper and raise its back enough to increase the capacity to about double what it is now. A 12¼ × 15-in. engine is used to operate the scraper. The span between towers is 720 ft. Two of the scraper outfits are employed, their work being located as shown by Fig. 3.

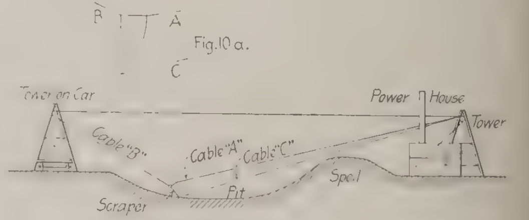

Fig. 10.—Diagram Showing Operation of Power Scraper.

Aldens Ridge Cut.—The deepest cutting which the canal will necessitate is where it passes through Andrews Ridge. Here the depth of excavation to canal bottom will be 92 ft., and the width of the cut at the surface is over 500 ft. The cut at Aldens Ridge is, however, only about 5 ft.

shallower, and, being somewhat longer, it contains more material. As will be seen from the profile, Fig. 3, a pretty good start had been made on the Aldens Ridge cut by Nov. 1. The material is very hard, being an indurated clay filled with boulders, and is peculiar in overlying a softer material, in fact, a soft blue clay, according to the borings made. To take out the hard material six steam shovels were at work at the time of our representative's visit. These shovels were loading into 5 cu. yd. dump cars hauled by locomotives to the spoil banks. Seven and eight cars are used to the train.

Fig. 13 is a view of the work on the top lift of the cut, and shows quite clearly the style of locomotive and cars employed. The shovel shown is one of the Vulcan Iron Works Co.'s special 75-ton shovels designed for handling ore. In the indurated clay and boulders the output of these shovels averages about 1,000 cu. yds. per ten-hour day. A 2½-cu. yd. dipper is used. As stated elsewhere, the steam shovel excavation will be carried down only to within about 5 ft. of water level in the canal, the remainder of the excavation being reserved for the vacuum pump dredge. These, as already stated, will be described fully in a separate article at a future date.

THE PROGRESS OF THE CHICAGO MAIN DRAINAGE CHANNEL.

Aside from difficulties of construction, the prosecution of the Chicago Drainage Canal has been beset with more difficulties during the past year probably than during any other year since work was actually begun. At the very beginning of the year's work legal troubles were encountered, and the litigation, once started, seemed to increase with every new piece of work undertaken. In his report of the canal work for the fiscal year ending Dec. 6, Mr. William Boldenweck, President Board of Trustees, Sanitary District of Chicago, outlines the nature of this litigation, its final decision and the delay produced by it on the work of construction. The following is a brief abstract of President Boldenweck's report:

> The last year has not been as prolific of good results as we anticipated. In fact, it was the year of lawsuits for this board and was the banner year in that line since the organization of the district. We had mapped out a great deal of work for the year—work that would have enabled us to complete the great drainage canal during the coming year and thus would have enabled the people of Chicago to have pure and wholesome water to drink in every home. It was only reasonable to expect that we would not meet serious obstacles that would retard this most important work.
>
> We met our first opposition in Joliet. Here the owners of the land we tried to purchase bitterly fought us at every hand. They placed the price of their land so outrageously high that it was impossible even seriously to consider their terms. We finally acquired the land by condemnation at about the prices we had originally offered for them. With the officials of Joliet the fight was quite as bitter. The matter was finally settled only after the board of trustees of the sanitary district has decided to abandon the plan of a large dam, which was to have been constructed diagonally across the river, and which would have left the streets at present grade. Thus was lost what would eventually have proved a great source of revenue to the district and a great benefit to the city of Joliet—the 9,000 HP. water power.
>
> The negotiations with the Illinois & Michigan Canal commissioners had been pending nearly a year. These were taken up again by the trustees of the sanitary district and the commissioners, with the result that a contract was entered into between the two boards which would protect both the interests of the state and those of the sanitary district. Plans in strict compliance with this contract were prepared and the money for the land acquired from the canal board was turned over to its treasurer, who gave his receipt therefor. Almost as soon as this money was paid over an injunction was prayed for against our board by the canal commissioners, which was granted by Judge Hilscher. Our attorneys at once filed affidavits looking to a dissolution of the injunction, which was not granted. However, the case was set for an early hearing, and after a month of preparation and trial the case was practically decided against the sanitary district. This was one of the most tedious and expensive lawsuits in which this district was ever a party.
>
> Under this decision the sanitary district will be compelled to spend several hundred thousand dollars more than was originally contemplated. Further than that, it received no additional benefit, it is delayed in the completion of the great canal and loses a large amount of money by reason of the outlay of more than $27,000,000 by the taxpayers up to this time which is for so much longer a period rendered useless. The matter has been taken up on appeal to the supreme court, where our attorneys will endeavor to get a speedy hearing.
>
> Another great disappointment to the trustees of the sanitary district was the eight-track bridge at Campbell avenue. Our engineering department, after months of hard labor, had designed the plans for a great swing bridge in this locality, upon which from time to time as the work progressed, the railroad engineers made suggestions. When our plans were finished bids were advertised for on this and also upon other designs that would prove acceptable to the railroads interested. When the bids were opened it was found that those upon our plans were the lowest. When the railroad officials looked into the plans and designs, that made by our engineering department was not acceptable to them. Then came the negotiations with the Strobel company and the Scherzer Rolling Life Bridge Co. for the purchase of their designs in order that all the builders of bridges in the country might compete for the construction.
>
> Bids on the two designs, as well as upon others, were received and opened, and a contract finally was awarded to the Scherzer Rolling Lift Bridge Co. The contract was awarded to the Scherzer company not because its bid was the lowest from the standpoint of dollars and cents, but because a majority of our trustees believed it the best bridge, and because the Strobel design had never been tried, and the Scherzer bridge was easier to operate and would cost less to maintain. A contract was entered into and approved, when the C. L. Strobel Co. obtained an injunction from Judge Payne, from which an appeal has been taken to the appellate court.
>
> The conclusion reached in the difficulties which presented themselves at Adams, Van Buren and Taylor Sts., I think, has been eminently wise and for the best interests of the sanitary district. If the land had been condemned, it would have involved, in my opinion, an immense cost, as the land is very valuable, and, furthermore, there would have been large claims for incidental damages by the railroad companies. In the first settlement you, as a board of trustees, entered into an arrangement with the Pennsylvania R. R. Co., at an annual rental for land used under its right of way for a by-pass at $3,000 a year. To the Chicago & Alton R. R. Co., we agreed to pay $116.68 a year for as long a term as the by-passes would be put to the uses of the sanitary district.
>
> A more perplexing problem was the widening of the river at the Northern Pacific bridge at Taylor St. This was because the land that was sought by the sanitary district was of such a character that if condemned and acquired it would destroy a large portion of the railroad company's business, and if a by-pass were built it would still leave the river in no condition to benefit navigation. There had been different committees appointed to confer with the railroad and city officials with the object of enlisting their co-operation in having a bridge constructed at this point that would have no center piers, in the interests of navigation.
>
> Nothing so far as financial aid was concerned was suggested, except by the Northern Pacific R. R. officials, who consented to stand one-fifth of the expense of maintaining the old bridge, while a new one was being built. This company also offered to pay one-fifth of the cost of creating the interlocking system of switches and the changes of the tracks. You finally accepted this offer, and the right to use the Scherzer rolling lift bridge was purchased, in order that as wide a scope of competition might be obtained as was possible. This was made necessary by the decision of Judge Payne, who claimed it was not in accordance with law to advertise for proposals on more than one design or pattern for a bridge.
>
> It is exceedingly gratifying to note the confidence in which the sanitary district securities are held by the public and investors everywhere. This is nowhere made more apparent and manifest than in the sale of our bonds and warrants. The former have been issued bearing 3½% interest, and bringing a premium of 103. .6%. Our warrants issued at 4% are eagerly sought by investors. For the information of the board of trustees, I give the results of the sale of bonds, rates of interest and premiums received from the commencement of the canal work up to the present time:

Date of issue.	Amount.	%	Price.	Sold to
Nov. 1, 1992.	$2,000,000	5	101.51	Blair & Co.
Jan. 1, 1894.	3,000,000	5	101.793	N. W. Harris & Co.
Aug. 1, 1894.	3,000,000	5	100.5707	N. W. Harris & Co.
Feb. 1, 1895.	4,000,000	4½	100.5	N. Y. Life Ins. Co.
Feb. 1, 1896.	800,000	4½	100.6345	First Nat. Bank.
Jan. 15, 1897.	800,000	4½	102.146	Mer. Loan & Tr. Co.
July 1, 1898.	200,000	3½	103.66	Home Sav. Bank.

> Our warrants drawn against the tax levy have also decreased in the rate of interest in like proportion as the bonds, and to-day are eagerly sought by investors at the rate of 4% per annum.
>
> Our arrangements with the city of Chicago regarding the construction of conduits and intercepting sewers have been very satisfactory. When these systems are once completed there will be no more pollution of our drinking water. This agreement has not yet been put into the form of a contract, but it is virtually binding by reason of an ordinance passed by the sanitary district trustees and accepted by Chicago city officials.
>
> Under this agreement Chicago is to build all the conduits, intercepting sewers, buildings for pumping stations and properly to equip them with the latest improved machinery, which the sanitary district will operate and maintain forever. This will not work a hardship upon our citizens, as the money is derived from the same source in either case. But the city's resources being necessarily limited in comparison with the amount it actually needs, the sanitary district is enabled to assist in this matter, and does so gladly in the interest of the people of the city of Chicago, especially when it is considered that through the aid of the conduit on 39th St. it receives an increase of at least 375,000 gallons of water per minute.
>
> The construction account shows that the expenses, according to an approximate estimate, have been $22,616,781.36 to date. Of this amount $20,048,525.14 has been audited. Fifty cases against the sanitary district are pending in court. The estimated balance required for the completion of the work July 1, 1900, is $5,225,649.27. The resources of the district to the same date are $6,226,472.92. The net receipts from the day of the organization of the district to Dec. 1 have been $28,077,012.54, and there is a balance of $121,231.88 on hand. (Additional figures of the cost of the canal work will be found in a communication from Chief Engineer Isham Randolph published in our correspondence column this week.—Ed.)
>
> During the coming year the committee on engineering will undoubtedly devote itself to the construction of bridges. Plans and specifications are yet to be considered for the following in Joliet and Chicago: Cass St., Jefferson St., extension of Rock Island bridge in Joliet, extension of Van Buren and Canal St. bridges and Throop St. bridge in Chicago. In the case of the Throop St. bridge, it may not be necessary to build a new structure, but we may be able to utilize the bridge now at Taylor St., where a new bridge is to be constructed of the Scherzer rolling lift bridge type. There will also come up the question of the removal of the Henry and Copperas Creek dams. The law makes it part of the duty of the sanitary district to remove these dams, as well as any other obstructions to the flow of water in either the Illinois or the Des Plaines rivers.
>
> The improvement of the great Calumet region is a matter that should not be lost sight of, as well as the improvement of the north branch of the Chicago River.
>
> There are fifty-four cases pending, in which the sanitary district is a party. It is incumbent upon the committee on judiciary to put forward every effort to bring these cases to speedy trial or settlement before the term of the present board expires.
>
> It was for me a gratification when an opportunity offered itself to open negotiations looking to a settlement of all difficulties between the board of Illinois & Michigan Canal commissioners and the sanitary district. Aside from the contractors clamoring for an opportunity to proceed with their work, the great cost of litigation and the loss of over $3,000 a day for interest on the investment, the gravest feature is the delay in the opening of the channel. It is, therefore, not good policy to be penny wise and pound foolish. We have tested our grievances in the court and have the verdict. It is true we were not beaten in the court of last resort, but who of us wants to stand idly by and wait for uncertainties when a compromise can be made for a smaller sum than the decree of the lower court demands from us? The canal commissioners have on this occasion reduced their demands to such an extent that the trustees of this district can take the matter in hand and conscientiously vote for a final settlement of these perplexing and stubbornly contested questions.
>
> The delay so far can, in my opinion, be made up to a great extent by requesting the contractors to work extra shifts, and it may be possible that the weather will be favorable to prosecute the work on the two delayed sections during the winter months. The committee on engineering should take this matter in hand as soon as the agreements between the canal commissioners and the sanitary district are executed and arranged with the contractors to make up for time lost.

Since the above statement of the litigation with the Commissioners of the Illinois & Michigan Canal was made, a compromise has been agreed upon between them and the trustees of the sanitary district. The details of this agreement are not yet made public, but it is stated that by it the drainage canal work can be resumed at once.

TWO NEW EAST RIVER BRIDGES connecting New York and Brooklyn are urged by Mayor Van Wyck, of Greater New York, and at his request the Municipal Assembly has appropriated the sum of $100,000 with which to pay the expenses of preliminary surveys, plans, estimates, etc. The Commissioner of Bridges has already begun work to secure this information. The location advocated for the first of these bridges, as was noted in Engineering News of Dec. 1, is at Blackwell's Island, the eastern terminus being in Long Island City. The second bridge, Mayor Van Wyck thinks, should be located somewhere between the present Brooklyn Bridge and the New East River bridge under construction, two miles north. The plans will be drawn for a bridge to accommodate general surface and elevated railway cars and street traffic.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, **$5.00**; *6 months,* **$2 50**; *2 months,* **$1.00.** *To all other countries in the Postal Union: Regular Edition, One Year,* **$7.60** *(31 shillings); Thin Paper Edition, One Year,* **$6.31** *(26 shillings). SINGLE COPIES of any number in current year,* **15** *cents.*

In ordering changes of mailing addresses, state BOTH old and new addresses; notice of change should reach us by Tuesday to be effective for the issue of the current week. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 *means that subscription is paid to the 32d week (that is the issue of Aug.* 11) *of the year* 1898; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: **20** *cents per line. Want noticees, special rates, see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

The report of Chief Engineer C. C. Martin, M. A. M., Soc. C. E., respecting the ability of the Brooklyn Bridge to carry safely its present loads, is a plain statement of facts which was much needed to disprove the silly stories of danger and disaster which have been recently published by some of the New York "yellow" journals. Among those best informed, it is almost needless to say, there has never been any doubt of the ability of the bridge to carry its additional load of elevated railway and surface electric cars with absolute safety. It has been equally recognized, however, that if this load was not uniformly distributed, that is if the cars were to be frequently bunched together over one portion of the suspended structure while other portions were clear the strains in certain parts of the structure might assume an undesirable and perhaps an unsafe character. Both of these facts have received ample recognition in Chief Engineer Martin's report. The accident of July 29 was directly due to the disobedience of the rules established by the expert engineers to regulate the trolley car traffic, and, as we stated at the time, the damage done, while immaterial in itself and certainly of no permanent injury to the supporting power of the bridge as a whole, was sufficient warning that the proper precautions in loading the bridge should not be lightly neglected. With the present careful regulation of traffic, a repetition of the accident, as Mr. Martin points out in his report, is little to be feared. That there is any danger of the cables breaking or the anchorage pulling up, as has been so alarmingly asserted by sensational daily papers, cannot be seriously assumed for a moment, with far greater loads even than those to which the bridge is now subjected. But even if the bridge were now loaded far nearer its limit of strength than it is, it would be very unwise to take the backward step of ordering the surface street cars and elevated trains from it and return to the old shuttle train system as has been proposed by some. It would be far better to expend money in strengthening the bridge to withstand the extra load. Some interesting statements respecting such a partial renewal of the bridge have recently been made by Mr. Wm. H. Hildenbrand, M. Am. Soc. C. E., in a letter to the "Railroad Gazette." Basing his estimates upon the cost of strengthening the Covington & Cincinnati suspension bridge, of which work he is the engineer, Mr. Hildenbrand calculates that the strength of the Brooklyn Bridge can be doubled at an expense of about $2,500,000. This work could be done without restricting traffic and would practically amount to the construction of another bridge in the additional facilities furnished for East River transit.

◆

The appropriation of $100,000 with which to pay the expenses of preliminary surveys for two new bridges between New York and Brooklyn is briefly noted elsewhere in this issue. In his message requesting this appropriation, Mayor Van Wyck, it will be noticed, instructs the Commissioner of Bridges to locate one of the new structures somewhere over Blackwell's Island, and the other between the present Brooklyn Bridge and the New East River Bridge, which is being constructed about two miles further north. The character of bridge which is approved for both places, also, is a structure for general purposes and not an "all railway" bridge. Admitting that these two new bridges across the East River are needed, engineers may, we think, justly question whether the location and character of bridges advocated is entirely wise. In the nature of things the Blackwell's Island Bridge cannot have any large amount of local traffic for many years. A brief study of the map makes the reason for this clear. The population of the territory north of Newtown Creek, where the bridge centers, is small, while the more thickly settled district south of Newtown Creek has a much more direct route to Manhattan Island by the new East River Bridge. A field of usefulness in which a bridge at Blackwell's Island promises much, however, is in providing steam railway connection between Manhattan and the suburban towns of Long Island. A vast growth of population and traffic in this direction is possible as soon as direct railway connection can be had across the East River, and by combining with the Long Island R. R. to build a steam railway bridge over Blackwell's Island the city will bring about a really beneficial public improvement. It is not clear at present, however, that the local traffic for many years to come would justify the expenditure of from four to seven millions of dollars in a bridge designed only for general street traffic and street railways.

Further downstream, on the contrary, a bridge designed for general traffic is essentially demanded. It is very doubtful, however, whether the location which Mayor Van Wyck advises is the wisest one. For all the territory north of the New East River Bridge that structure is the natural route to New York, and for all the territory south of the present Brooklyn Bridge that structure gives the most direct connections. As a matter of fact a new bridge located between these two would afford a quicker and more direct route than they to only a very small territory. It needs only a very brief study of the map to convince one of this beyond any reasonable doubt. A part of Brooklyn, however, whose growth in business and population justifies the attention of the city authorities in their work of supplying a better East River transit, is South Brooklyn. Were the natural difficulties to bridge construction no greater here than they are further upstream there could be no question as to the superior advantages of this southern location for one of the proposed bridges. It is to be hoped, therefore, that while Mayor Van Wyck and Bridge Commissioner Shea have the question of additional East River bridges in hand they will give the matter of a bridge to South Brooklyn due study.

◆

Elsewhere in this issue is given a description of the electric rack railway now being constructed to the top of the Jungfrau, in Switzerland. This road is exciting considerable interest among engineers owing to the fact that the dangers and difficulties of surmounting an Alpine peak nearly 14,000 ft. high are to be avoided by tunneling the entire distance from the point near the foot where the maintenance of a railway in the open becomes difficult and dangerous to a point directly underneath the highest point of the mountain, which will be reached by elevators in a 250-ft. vertical shaft. The plan contemplates about 6½ miles of single track tunnel through the solid rock, a track constructed in the most substantial manner, two electric power stations, suitable for high voltage, transmission lines, and transforming stations where the current will be stepped down to lower pressure and delivered to conductors along the track, the whole involving an expenditure of nearly $2,000,000. This estimate for the cost of construction certainly appears small, but it is probable that those backing the scheme have satisfied themselves on this point.

The estimated number of passengers per year is placed at 10,000, which would seem a very conservative figure, considering that in the season of 1895 fully 160,000 persons visited Interlaken, only a few miles distant from Little Scheidegg, the starting point of this road.

It is of interest to note that the actual altitude reached by the Jungfrau railway is about the same as that reached by the Pike's Peak railway in Colorado. The reason for the great difficulty and danger in climbing Alpine peaks as compared with those of similar altitude in the Rockies, is to be found in the moister and cooler climate of the Alps, which keeps all their upper portions clad in perpetual snow and ice, and produces glaciers and avalanches.

The Division of Hydrography of the U. S. Geological Survey is engaged in the exceedingly useful work of bringing together for publication all available data concerning the water resources of the United States. This Division was organized in 1888, and the reports made are printed as separate volumes of the annual reports of the Geological Survey, and they already make an exceedingly valuable contribution to knowledge on this most important subject. In order to round out the general information now in hand it is desirable that the Division be placed in communication with all parties interested in this subject, and this list would include civil, hydraulic and sanitary engineers, instructors in these subjects, members of boards of health, and biologists and chemists interested in water supply. From the notes made by these men in the course of professional work it is hoped that the Division of Hydrography may be furnished, by correspondence, with any data relating to the following heads: Quantity of stream flow, if even the result of a single observation upon any stream in the United States; quality ot water; natural lakes and ponds, with any information as to origin, size, depth, fluctuation in volumes or changes of temperature; irrigation canals and ditches; water power; storing and pumping water; pollution of stream, with the increase of population and development of industries; and of deep or artesian wells. Engineers and all interested in the development of the water resources of this country can further a work of the utmost importance to themselves and to the country at large, by either forwarding any such data that they may possess to Mr. F. H. Newell, Hydrographer, U. S. Geological Survey, Washington, D. C., or by sending in to Mr. Newell the names and addresses of those likely to possess such information. The work of this Division is one of the most generally useful and commendable falling within the province of the Geological Survey; and it is to be earnestly hoped that all available data on water supply will be placed at its disposal. Much information on this head is now hidden away in private note-books which if collated with similar data and made public would be of great value to the profession.

The letters published in our issues of Dec. 1 and Dec. 8 respecting the financial status and methods of operation of the Quebec Bridge Co. and the Montreal Bridge Co, have brought us several letters from Canadian engineers, warning bridge building firms and engineers in the United States to investigate very carefully the financial status of the Quebec Bridge Co. before expending money upon plans and estimates in response to its call for proposals. We judge, however, that what has already been printed in these columns will be sufficient to ensure this being done without our tak-

METHODS OF WORK ON THE ST. LAWRENCE POWER CO.'S CANAL.

St. Lawrence Construction Co., New York, N. Y., General Contractors.
The T. A. Gillespie Co., New York, N. Y., Contractors for Work.

ing space to print these letters and the rejoinder which, under our rules, we should be obliged to give the company criticised an opportunity to make. If the company can prove that its financial status and prospects are such as to warrant bridge builders in preparing plans for its work, those from whom it is soliciting such plans will doubtless not hesitate to demand the proof and to give it careful scrutiny.

PLAIN WORDS ABOUT THE MORGAN BILL FOR PURCHASING THE NICARAGUA CANAL CONCESSION.

There can be no doubt, in the mind of any one who keeps in touch with public opinion, that the events of the past year have made the American people practically a unit in favor of the construction of the Nicaragua Canal. Public sentiment at the present time would probably heartily approve the undertaking of the canal as a Government work. The idea has taken strong hold of the popular mind that the canal is essential to our national defence; and a large section of the country, including especially the Pacific coast and the states bordering on the Gulf of Mexico, is well persuaded that the construction is needed as a means of securing its commercial prosperity.

But the problem, as it is now before Congress, is not the simple one of deciding whether the nation shall take the funds from its treasury and build the canal as a national enterprise. The scheme as it is now presented to the Senate is for the United States to revivify the old Maritime Canal Co. of Nicaragua, and to build the canal under that name, incidentally paying to the holders of the stocks, bonds and other obligations of that bankrupt concern, some five million dollars, more or less. Now while public sentiment, as we have said, strongly favors the costruction of the canal, it is inclined to scrutinize very closely such roundabout methods of procedure as are proposed in the Morgan bill, now before Congress. Past experience has taught the public that partnership arrangements between a state or a city or the national government and a private corporation are to be looked upon with much suspicion.

To explain fully the present situation we shall have to review briefly the recent history of the Nicaragua enterprise. When the Maritime Canal Co. obtained its concessions from Nicaragua in 1888-9, it expected to raise capital in the financial markets of the world sufficient to complete the canal as a private enterprise. In fact, the concession from Nicaragua distinctly forbid the transfer of the concession or of the control of the company to any nation or government. Any such transfer was to work the forfeiture of the concession.

After securing its franchise and making its surveys, the canal company's promoters set about the task of securing funds; but in this it was unsuccessful. The investing public of the world refused to be convinced that the success of Suez could be repeated in Nicaragua, and while the company did raise the considerable amounts that were necessary to pay for its surveys and such preparatory work as it undertook, it did this by disposing of its securities at a great sacrifice. It became evident that the canal was too risky a scheme to attract private capital; if built at all, it must be as a Government work; and the managers of the canal company, as the only hope of securing a return for the money they had put in, began their endeavors to dispose of their concession to the Government. At nearly or quite every session of Congress for the past seven years, bills for this purpose have been before Congress; and their advocates have pushed them in a manner which gave good ground for their belief that they were more concerned in the rescue of the canal company's stock and bondholders from loss than they were in the protection of the Government's interests, and securing the construction of the canal.

The general scheme in the various bills before Congress has invariably been to have the Government guarantee the bonds of the canal company to the amount of about $100,000,000, and receive in return $70,000,000 of the company's stock. As it became more and more evident that Uncle Sam could not be induced to pull chestnuts out of the fire to any such extent, the Maritime Canal Co. have reduced their demands. In the bill as presented by Senator Morgan last June, according to the best information at hand, it was proposed to give the canal company stock and bondholders and creditors $4,500,000 in bonds and about $7,000,000 stock in exchange for their present holdings. In the bill as reported by Senator Morgan on Dec. 7, this has been changed, and it is now proposed to give the company the sum of $5,000,000 in bonds for all it has and owns, and to wipe out all obligations of every kind. The old company is, in fact, to disappear, and the new company under the same name is to be practically a department of the United States Government, all its directors being appointed by the President.

There are two questions which ought to be definitely settled before Congress passes the bill for which Senator Morgan has so zealously labored. The first is what the United States is to receive for the $5,000,000 which it is asked to pay, and second, whether it is desirable that the Government shall masquerade as a private corporation in carrying out the work of building this canal.

The actual visible assets of the Maritime Canal Co., and its Construction Company offshoot, are admitted to be trifling in amount. There is about 11 miles of railway embankment running west from Greytown, across the swamp section, on which, according to all accounts, the ties have disappeared and the rails are fast approaching the traditional two streaks of rust. The Greytown harbor works have been wiped out by the sea-worms and the silt carried by the tidal currents. There are a few buildings at Greytown and a small amount of machinery, dredges, etc., all of which has experienced the deterioration due to half a dozen years of tropical exposure. Finally, there is, or was, a couple of miles or so of ditch dredged through the swamp. It seems to us that the fair basis for estimating the value of this plant is to see what it would be fairly worth, or what amount of expenditure its use would save if the Government should now undertake to utilize it in the construction of the canal. From all the information available, it seems probable that the sum of $200,000 would be ample to cover the value of the existing plant and works on the basis above outlined.

The second asset which the Maritime Co. has to dispose of is its surveys, and the maps, plans, designs, etc., which were made by its corps of engineers. Just what value may be fairly placed on this asset, it is difficult to say; but there are good reasons for declaring that the estimate should not be a high one. Much of the work done by the company's engineers was in working up the details of its high-level navigation scheme from the Ochoa dam to the great divide cut. The defects and dangers of this plan are now well known, and it is probable that the canal, if built, will pursue a different route from the great divide cut to the San Juan. Similarly on the western division, it is not at all certain that the canal company's location will be the one adopted. Under these circumstances, the canal company, it seems to us, can hardly claim payment for its work in fixing a location which is afterward discarded.

On the other hand, it is certainly true that a considerable amount of the topography taken and borings made by the company will be of use to the United States; and if this is so a fair valuation should be placed on this work. We cannot pretend, of course, to name anything more than approximate limits to the estimate of such work, but it seems to us that the sum of $300,000 should be ample to cover it, or a total of $500,000 for the entire works, surveys and records belonging to the company.

The remaining asset of the company is its franchise from the states of Nicaragua and Costa Rica, and it is this which Senator Morgan and the canal promoters have chiefly urged as worth the price which they have asked the Government to pay. Recent events, however, have not been calculated to improve the position of those who value this franchise so highly. As our readers already know, Nicaragua has taken formal action declaring that the franchise will be forfeited next October, and has granted a new franchise to a new set of financiers which will go into effect when the Maritime Canal Company's franchise expires.

The ground on which the franchise is declared forfeited is the following clause in the Maritime company's charter:

> Article 43. A term of ten years is also granted to the association for the construction, completion and opening of traffic and the canal for maritime navigation. However, should events of main force arise, duly justified and sufficient to impede the regular progress of the works during the period of the said ten years, an extension shall be granted equal in duration to the time that may have been lost by such delays. If at the expiration of the ten years aforesaid the works should not be completed so as to have the maritime connection between the two oceans opened, in consideration of the great capital the company may have invested in the enterprise and the good will and ability it may have shown and the difficulties encountered, the republic binds itself to grant a new extension."

The phrase "events of main force" is indefinite, it is true, but the idea apparently is to give the company the benefit of an extension to compensate for delays due to strikes, wars, pestilence, earthquakes or other great public calamities. It can hardly be seriously contended that the clause had reference to mere inability to finance the enterprise.

The second clause of the article evidently refers to the situation which would have existed had the company proceeded with actual construction and been unable to complete the canal within the specified time. Had it done this, it might without doubt claim of Nicaragua an extension of the franchise period. As the case actually stands, however, the company can hardly claim to have invested "great capital" in the enterprise; the "ability" has certainly not been manifested in the actual work of construction, and "the difficulties encountered" are not such that an extension of the contract period would be of any benefit to the company, unless it can turn over its franchise to the Government, which the terms of the franchise distinctly forbid.

This, then, is the situation. The United States is asked to pay $5,000,000, more or less, for a franchise, which will in the first place be invalidated on its face by transfer to the Government, and which, in the second place, has been declared by the state that granted it to be forfeited by its own limitation at a date only nine months distant. The present holders of the franchise claim, indeed, that for various technical reasons, which we cannot take space to enumerate, they have a right to an extension of the time allowed for construction; but they have not obtained such an extension.

Suppose Congress passes the Morgan bill, and the United States purchases this concession. Shall this great and powerful nation then compel Nicaragua by force or by the threat of force to reverse its formal action terminating the Maritime Canal Company's concession? Of course we can do this, if we choose; but it would be an act for which every self-respecting American would blush with shame. Nicaragua is an independent state, insignificant, it is true, but nevertheless entitled to the same just treatment at our hands as any other friendly power. It is not long ago that we rapped England over the knuckles to remind her that might did not make right. We then established the principle that a stronger power may not dictate to a weaker, when the latter offers to submit its case to arbitration by disinterested parties. Shall we use compulsion in Nicaragua, when we compelled England to refrain from compulsion in Venezuela?

We believe that there can be but one answer to this question in the mind of any intelligent American. If we purchase the franchise which Nicaragua has declared forfeited, we owe it to ourselves to treat her claims with the same respect that we would if they were made by France, or Germany or Russia. If Nicaragua appeals to arbitration to decide whether her annulment of the Maritime Canal Company's franchise was warranted, to arbitration it must go. In other words, this Government must take up the dispute of the Maritime Canal Co., before some international tribunal, and must go into all the petty details of the various negotiations between Nicaragua and the canal company extending over a period of a dozen years. The result of such an arbitration must at best be doubtful, for, as we have seen above, Nicaragua had, it is extremely probable, a legal right to terminate the Maritime company's charter. The time such an arbitration would occupy can be estimated by recalling the fact that the arbitration between Great Britain and Venezuela has not yet reached an end. Surely, then, the passage of the Morgan bill is not the way to hasten actual construction of the canal. On the contrary, the purchase of the Maritime Canal Company's charter can only land us in a maze of complications, of which no man can discern the outcome. The excuse which has been given for pushing the Morgan bill before Congress in advance even of the report of the engineering commission, is that haste is demanded in the work of actual construction. The flimsy nature of this excuse is now apparent

Let us next consider the question whether if the United States is to construct the canal, it should do so under the guise of a private corporation. The stock reason for this course has always been that it was a way of getting around the Clayton-Bulwer treaty, under which we agreed to join hands with England in the construction and control of the canal. No more peurile argument was ever conceived. If the United States can own the franchise, furnish the money and hold practically all the securities of a company organized to build the canal, it can equally well undertake it as a piece of public work as it would any river and harbor improvement, so far as its obligations under the Clayton-Bulwer treaty are concerned. It has been claimed for American diplomacy that it is straightforward and frank; and that we scorned subterfuges and technical evasions, holding to the spirit rather than the letter of our obligations. What becomes of this claim if we try to get around a treaty with England, our best friend among the great powers of the world, by such a transparent evasion?

There are other reasons why the United States should not pose as a fictitious corporation to build this canal. The checks and safeguards which long experience has developed to protect the Government from fraud in the execution of, its works would all be eliminated if it were to do this work under the guise of a private corporation. The eleven directors appointed by the President would have free and unchecked control over expenditures amounting to over a hundred million dollars. What a chance for corruption and plunder! Is it some foresight of this and of the harvest that will await those who may expect to have the spending of this enormous sum that causes the unseemly haste to rush the Morgan bill through Congress at the beginning of the present session?

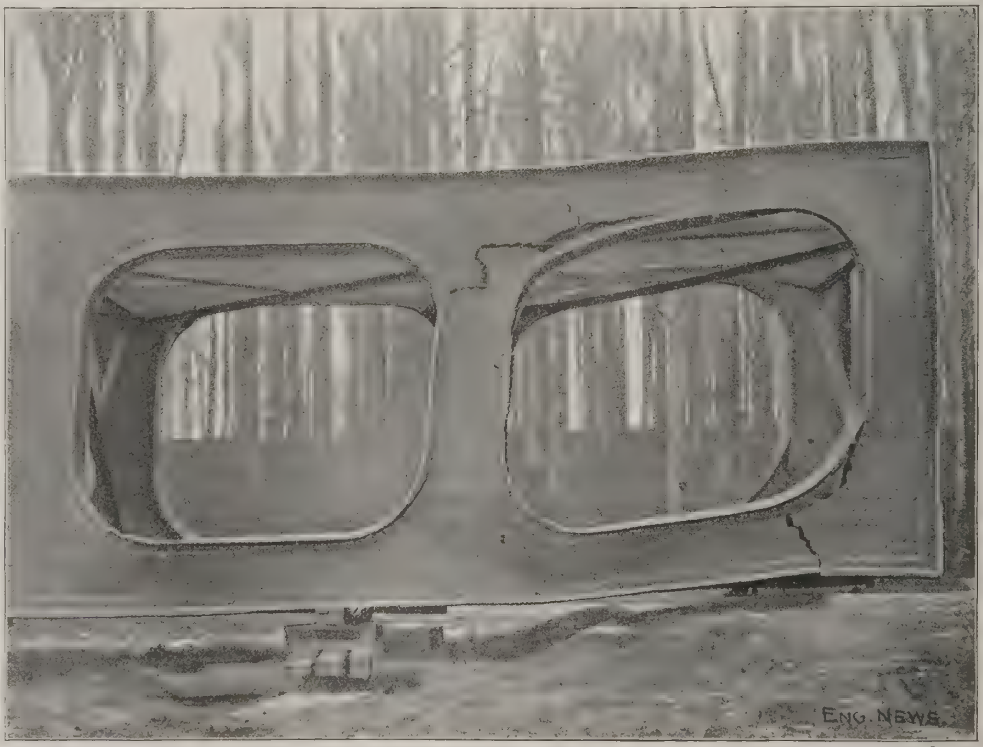
Let us turn now to another aspect of this question. Those who are endeavoring to push the Morgan bill through Congress are privately urging upon the Senators and Representatives that it is really as a measure of justice to those who have invested their money in the canal enterprise that the Morgan bill is desired. They acknowledge that the existing plant and the records and surveys of the company are only worth a small sum, and that the company's franchise is practically void; but they urge that those who put their money into the canal enterprise should not be compelled to suffer total loss. They claim that motives of patriotism, as well as the hope of profit, influenced many of those who invested their money in the company's stock and bonds, and that it will be unjust and unfair for the United States to now take up and complete the enterprise and leave in the lurch those who carried it through its initial stages.

We are far from denying that there is some reason in this presentation of the case. It is quite possible that the nation ought to pay to those who in good faith spent money upon this enterprise, something more than the present value of the plant and surveys. But what we would urge is that if this is to be done, let it be done openly and squarely. Let it be plainly understood that the Morgan bill is a bill to repay to Maritime Canal stock and bondholders their expenditures upon the enterprise. If this is not done, and the bill is passed in its present form, the certain result will be a scandal and an investigation, which will very probably put the action of many members of Congress in a worse light than they deserve It may be just and equitable to pay $5,000,000 to Nicaragua stock and bondholders; but the people will not be convinced that there has not been wholesale fraud if this payment is made in the guise of purchase money for something worth only a tenth part of that sum.

Still another serious question to which Congress should give heed is the question what is to become of the $5,000,000 which it is proposed by the Morgan bill to turn over in a lump to the Maritime Canal Co.? How much would the genuine investors in the company receive, and how much would be diverted on one pretext or another into the pockets of those who have already made profits by their manipulations of the company's stock? How much of the five millions would be allotted to those who paid for their stock only in "influence?" Are some of the newspaper proprietors whose journals have been most vociferous in urging the speedy passage of the Morgan bill to have a goodly share? Is the anxiety to further the interests of the Maritime Canal Co. which certain high public officials have displayed, explainable on any other grounds than pure unadulterated patriotism?

These are some of the questions which the public would like to have answered before Congress turns over five million dollars of the public money to the Maritime Canal Co. If the bona-fide investors and creditors of that company are deserving of relief at the hands of the Government it is surely not too much to ask that the company shall open all its books to public inspection, and that some pains at least shall be taken to see that the money goes to those who have a reasonable claim upon it, and is neither gobbled up by those who are on the "inside," or frittered away in litigation.

We have given in detail the reasons why the passage of the Morgan bill is not the road to speedy construction of a Nicaragua canal. Just what course Congress should take to this end, lack of space forbids us now to discuss. This much, however, is clear: that the acquisition of the Maritime Co.'s concession will give the United States nothing, either as respects the Clayton-Bulwer treaty, or its relations to Nicaragua, that it cannot better and more quickly attain by direct diplomatic negotiation through its own accredited agents. The quicker Congress makes clear that it is not in the business of bargaining with concession-mongers, no matter what their political or financial backing, the more certainly will the public confidence in the Government's ability to handle the many grave problems now pressing upon its attention be confirmed.



END PANELS OF A VIERENDEEL GIRDER OF 103 FT. SPAN, AFTER SUBJECTION TO A BREAKING LOAD.

LETTERS TO THE EDITOR.

Portable Forges with Detachable Parts

Sir: In the Dec. 1 number of your valuable journal you illustrate and describe a forge put up by the Buffalo Forge Co. It is, at least, intimated in the article that the forge is new.

Please look over the enclosed illustrations of our forges. A comparison of the two forges may be interesting. You may never have seen our machines. Some of your advertisers use them. Our forges built the good ship "Oregon."

Yours truly,
David Cumming.

278 N. Hoyne Ave., Chicago, Ill., Dec. 9, 1898.

(The forges illustrated in the circulars enclosed with the above letter show many points of similarity to the one illustrated in our issue of Dec. 1st.—Ed.)

A Remarkable Belgian Bridge Design.

Sir: We send you herewith the latest, if not the most brilliant, development of Continental bridge engineering, entitled "The Bridge System of Vierendeel." This monograph was sent to us by a friend of ours now in Europe, whose desire to give us valuable information exceeds his engineering discrimination. We believe that the bridge engineers of this country will find it amusing, if not convincing, and that they will agree with the writer that the true inwardness of the design is an attempt to patent a hole in a web plate, and the bigger the hole the greater the invention.

It is difficult to imagine what diagonal web members have ever done to this inventor that he should leave them out in the cold. He seems to know of their existence, as witness the sway bracing, and if filletted holes are good enough for the main trusses, why should he not use them for sway bracing? It is needless to point out that the liberal width of his vertical members and the liberal size of his corner fillets enables the structure to show some resistance under load, but what shall we think of an engineering community which would give grave consideration such a monstrosity?

Yours truly,
H. S. Wood, C. E.,
Engineer San Francisco Bridge Co.

World Building, New York, Dec. 6, 1898.

(The pamphlet to which our correspondent refers was briefly noted some months ago in our column of "New Publications." It is quite as remarkable a curiosity as the above letter would indicate. The design will be apparent from the accompanying illustration, which shows the two end panels of a bridge of this type which was broken under a test load at Tervueren, at the time of the Berlin International Exposition of 1897. The bridge had a span of 103.3 ft., and a depth of 10 ft., and was designed for a railway bridge to carry a load of about 3,150 lbs. per lin. ft. The inventor claims an economy in material "which increases with the span," and attempts to defend himself against the charge of costly construction. The "Notes for the Jury," as the work is entitled, enters into an elaborate description of the principle advocated, and into the calculation of values to be obtained. In the actual test, the weight was applied in the form of pig-iron; and though the claim was made that the structure would carry 600 metric tons distributed load before breaking, it actually failed, in the web system, as shown in the cut, under a load of 410 to 420 tons. The inventor explains this by saying that it was "impossible to apply the load fast enough"; and the fact that it was loaded with 370 tons over night "accounts for the mischief." To an American engineer the manner of failure is decidedly interesting, as it shows that the structure failed exactly where theory would indicate probable failure. The inventor's bridge is made up of rectangular instead of triangular elements, and while its weakness is somewhat concealed by the riveted construction and the bracing at the corners of the rectangles, it is, of course, an engineering absurdity.—Ed.)

Estimated and Actual Cost of the Chicago Drainage Canal.

Sir: It is not my purpose to mix up with the entanglements of the Erie Canal, but I cannot let statements made, in ignorance of the facts, by Mr. George W. Aldridge, Supt. of Public Works, under date of Oct. 30, and quoted in your issue of Nov. 3, 1898, go uncorrected so far as they relate to the Sanitary District of Chicago and its work. You quote him as saying that he "challenges the commission or the public in general to point to any work of similar magnitude where greater diligence has been shown or where the estimates have come as near to accomplishing the work required to be done as has been accomplished in this instance." Then follows an alleged table of "comparison" between the original estimates and the actual cost of various notable public works:

	Estimated.	Actual.
Erie Canal	$4,926,738	$7,143,789
Enlargement	23,402,863	32,008,851
Oswego Canal	227,000	565,437
Enlargement	1,926,339	2,511,992
Champlain Canal	871,000	1,746,062
Black River Canal	1,068,437	3,157,298
Hoosac Tunnel	1,948,557	20,241,842
Manchester Ship Canal	26,000,000	67,351,105
Chicago Drainage Canal	12,000,000	*37,671,652
Hudson River Improvement	2,000,000	2,600,000
State Capitol, Albany	4,000,000	24,000,000

*This includes $27,303,216, and an estimate of $10,538,436, to complete the work.

In his table of comparison of estimated and actual cost, he gives for the Chicago Drainage Canal, estimated, $12,000,000; actual, $37,671,652. Where does he get these figures? For five years and six months I have been Chief Engineer of this work, and no such figures have ever come under my observation. Turning to the Records of the Board of Trustees, we find, on page 118, under date of Jan. 10, 1891, a report from W. E. Worthen, Chief Engineer, and John Newton, Consulting Engineer, from which I quote:

> We estimate the total cost of entire line of eighteen (18) feet water depth by way of Ogden Ditch at $25,700,000.

On pages 148-50 of the proceedings for March 7, 1891, will be found an address to the citizens of the Sanitary District of Chicago, signed by Richard Prendergast (then President), Arnold P. Gilmore, Christoph Holtz, Henry J. Willing, Trustees. In this address the estimate of Jan. 10, above quoted, is given with the addenda, "In this carefully prepared estimate the following items are not provided for: Right of way, dumping ground and transportation of waste material to place of deposit; further charges for straightening the South Branch of the Chicago River; changing bridges, etc., to produce a larger flow, to be done by the city."

The canal is now so nearly completed that the margin of possible error in approximating the cost of the unfinished work is very small, and we have a channel whose minimum depth of flow is not "fourteen feet," nor "eighteen feet," but twenty-two feet, and the work embraces not alone the main channel contemplated in the reports above referred to, extending from Robey St. to Lockport, but also covers the diversion of the Desplaines River; the deepening, widening and bridging of the Chicago River, and the deepening widening and bridging of the Desplaines River from Lockport to the mouth of Hickory Creek south of the city limits of Joliet. Nor is this all. The character of the work has been changed in many particulars from that contemplated in the original estimates, notably in the item of masonry; massive walls laid in cement mortar have been substituted for dry rubble. The bridges are being built in conformity to the heaviest modern specifications, and no proper expenditure necessary to make the work first class in every particular has been omitted. The resulting cost to the Sanitary District is shown in the following statement:

Cost of Main Channel and Auxiliary Work, Sanitary District of Chicago, Under Contract and Estimated to Date of Proposed Completion, July 1, 1900.

Construction.		
Diversion of Desplaines River	$1,000,156.38	
Main channel, Roby St. to Lockport	18,416,024.46	
Controlling works	245,536.65	
Railroad and highway bridges	1,318,236.71	
		$20,979,954.20
Chicago River improvement	$678,614.39	678,614.39
Desplaines River improvement from Contrlg Wks. to Joliet	690,823.77	690,823.77
		$22,349,392.36
Right of way and lands		3,141,807.62
Total for construction and lands		$25,491,199.98
Administration Account.		
Engineering, legal, clerical and police		2,080,789.62
Maintenance account		92,426.19
General account		480,115.21
		$28,144,531.00
Amount to be paid as capitalization for maintaining railroad bridges, etc.		267,389.00
		$28,411,920.00

The interest charges up to July 1, 1900, will amount to $3,469,804.85. Bonds to be retired, $830,000. To cover contingencies, an allowance of 10%, or $250,000 for unfinished work would be proper.

This exhibit is an ample vindication of the methods which have been obtained on this work and the results stand as a monument to the character and ability of the men to whom Chicago has intrusted the expenditure of its millions.

Yours truly,
Isham Randolph, Chief Engineer.

Chicago, Ill., Dec. 6, 1898.

THE ELEVATOR ACCIDENT IN THE MANICE BUILDING, NEW YORK CITY.

On the afternoon of Dec. 6 an accident occurred to the passenger elevator in the Manice Building, an 11-story office building, at the corner of Pine and William Sts., New York city, which caused the death of one man and the serious injury of two others, all of them passengers in the car at the time.

The accident was of an unusual character, consisting in the fall of several of the cast-iron weights forming one of the counterweights from the top of the shaft. According to the best information available, the accident appears to have occurred about as follows:

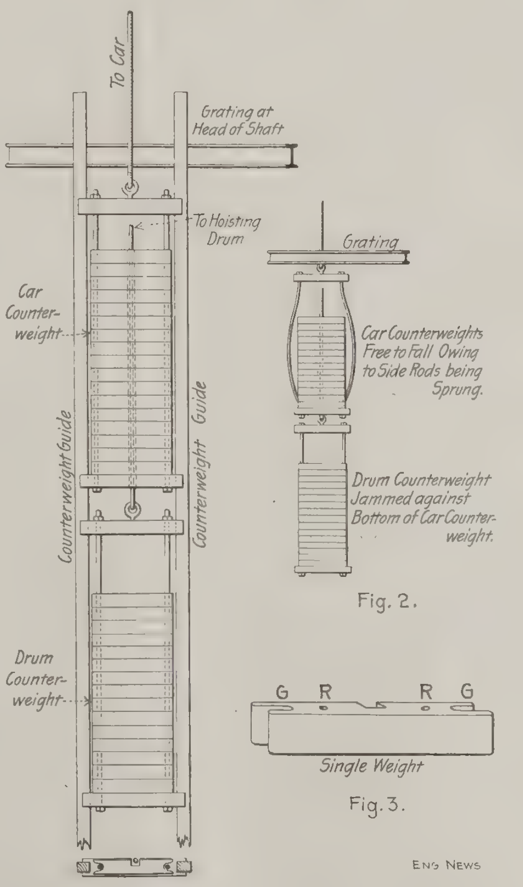

Fig. 1.

Sketches Showing Normal Position of Elevator Counterweights and Position at the Time of the Accident, Manice Building, New York city.

The elevator was descending from the 8th floor, where it had stopped to take on several passengers. At the 6th floor the elevator was stopped suddenly in response to a call from that floor, but as the car was crowded no more passengers were taken on and the down trip was continued, the motion being noticeably jerky and irregular. The final stop was made below the ground floor, the car striking the buffers with considerable force, and an instant later several of the cast-iron counterweights crashed through the frail car roof, after a fall of 11 stories, with the fatal results already mentioned.

The equipment was the standard Otis electric elevator, model of 1895, provided with limit stops, car safeties and the usual car control. Running up one side of the shaft were two counterweight guides for the two counterweights used. These were suspended, as shown in the sketch, Fig. 1, the upper one being the car counterweight, which is hoisted by the downward pull of the car, and the lower one the drum counterweight, which is hoisted by a cable wound on the hoisting drum in the opposite direction to the car lifting cable. Just under the sheaves at the head of the elevator shaft was the usual grating required by the city Building Department to guard against any part of the overhead machinery falling upon the elevator car.

The cause of the accident seems to be that the car on the down trip descended far enough below the lower floor level to jam the car counterweight against the overhead grating, and the closely-following drum counterweight striking the bottom of the upper weight lifted it and spread the suspending rods, as shown in the sketch, Fig. 2, sufficiently to free several of the weights, which toppled over and fell down the shaft. Referring to the accident and its cause, Mr. F. Frankenberg, City Elevator Inspector, is quoted as saying:

> The cause of the accident was that while the car was on the down trip the operator failed to judge the ground floor properly. The car struck the bumpers at the bottom of the shaft, causing the back drum weights to raise the car weights, thus tipping the car weights into the shaft. Had the automatic stop on the motor been set properly for the down stop, and the car properly stopped at the ground floor, the accident would not have happened.

In making repairs the old cast-iron car counterweights were replaced by lead weights, thus shortening up the counterweight and giving more clearance between the overhead work and the traveling weights. The single weights shown in Fig. 3 are the same in form as those so generally used for elevator counterbalances, but to avoid any possible future accident both counterweights will be provided with bolts running through holes drilled in the weights, at the points R, R, Fig. 3.

The accident will doubtless serve to call attention to the need of greater care in the designing of counterbalance weights and their attachments. The common method of assembling counterweights with nothing but gravity to hold the bunch of weights in position is objectionable; and it seems clear that the several weights should be firmly bolted together. Of course it goes without saying that the construction of the automatic limit stops should be such that by no possibility of careless handling can the car or counterweight bring up with a shock at either the top or bottom of the shaft. If the designer is unable to effect this with absolute certainty, then elastic buffers should be provided to receive the counterweights at either end of their travel and prevent their bringing up with such a shock as to cause undue strain in the ropes or other parts of the machinery.

* * *

SHIP-CANAL STATISTICS or the growth of commerce on the great canals of the world are treated by the U. S. Bureau of Statistics, as follows: The Suez Canal in 1869, when first opened, showed a net tonnage of 6,576 tons; in 1870 this was 436,609 tons; in 1891 the figures reached 8,698,777 tons, since which time there has been comparatively little change, the figures for 1897 being slightly below those for 1896. The Kaiser Wilhelm canal, in operation but three years, shows an increase of 50% in that period; or, 1,505,983 tons for the first year, and 2,469,795 tons for the fiscal year ending March 1, 1898. The St. Mary's Falls canal, connecting Lake Superior with the lower lakes, shows a more rapid rate of gain than Suez. In 1881 the freight tonnage through this canal was 1,567,741 tons; in 1885 it was more than three million tons; in 1887, over five million tons; in 1890 over nine million; in 1894 over 13 million, and in 1897 over 18 million tons. The freight tonnage passing through the Detroit River has also increased from 9,000,000 tons in 1873 to 23,000,000 tons in 1896. The Welland Canal shows a slight gain of from 819,934 tons in 1880 to 1,279,987 tons in 1896. On the other hand the New York State canals show a steady decrease in tonnage since 1880. In 1880 the freight carried to tidewater amounted to 4,067,402 tons; in 1890 this was 3,024,765 tons, and in 1897, 1,878,218 tons. In 1877 the average rates per bushel for wheat, from Chicago to New York, by lake and canals, was 11.24 cts.; in 1887 it was 8.5 cts.; in 1897, 4.25 cts. In the combination of lake and rail freights, the rates fell from 15.8 cts. per bushel, in 1877, to 12 cts. in 1887, and 7.37 cts. in 1897. All-rail freights fell from 20.3 cts. per bushel in 1877, to 15.74 cts. in 1887, and 12.32 cts. in 1897.

METHODS OF TESTING INDICATORS.*

By D. S. Jacobus, M. Am. Soc. M. E.†

Indicators should be tested both before and after they are used on an engine, or other trial. One object of testing the indicators before the trial is to make certain that there is no excess of friction, which, if present, will form double lines on the test diagrams. If double lines are found it is generally due to some irregular action of the spring, in either throwing the piston of the indicator out of line, or in forcing it against the side of the cylinder.

A mercury column will often give incorrect results when used in testing an indicator with steam pressure unless it is allowed to stand a long time at each pressure before taking a reading, on account of the fact that a considerable pressure is required to overcome the inertia of the mercury in the column if the latter is in motion, and there may be pulsations which will affect the result.

The apparatus used for testing indicators at ordinary pressures above the atmosphere is shown in Fig. 1. The indicator is placed at A on top of the cylinder B. The cylinder B is made of a piece of 6-in. standard pipe about 2 ft. long. The pressure is measured by means of a plug and weight device C, which is spun around so as to eliminate the effect of friction. The bottom of the plug is at the same level as the pipe D. The U-shaped pipe E is filled with oil. Before starting to calibrate the indicator the pet-cock F is opened slightly, in order to allow any air in the pipe G and the siphon H to escape. The siphon H is surrounded by water contained in the vessel I, which condenses the steam which enters it through the pipe D, so that when all the air present is allowed to escape through the pet-cock F, the pipe G and the siphon H will be filled with water. J is a pet-cock for removing any water that may collect at the bottom of the siphon E, after the apparatus has been in use for a long time. The pressure is adjusted by regulating the amount of opening of the valve K in the supply pipe L, which furnishes steam, water, or compressed air to the apparatus, and also by adjusting the valve M in the escape pipe N. O is a valve for removing any water which may collect in the bottom of the cylinder B when steam is used, and for draining out the water after calibrating an indicator under hydrostatic pressure. The plan of the plug and weight device C is limited in its movement by means of a fork, which comes in contact with it only when the pan is in the extreme positions; the two prongs of this fork are shown in section at P and Q. R is a gage for showing the approximate pressure. The readings of the gage R are not used in testing the indicator, but as general guide in the use of the apparatus. The diameter of the plug in the plug and weight device C is 0.5-in., and the hole in the bushing, 0.5005-in. Both the plug and bushing are ground true. The average area of the plug and of the hole in the bushing is used in calculating the weight required for a given pressure.

Fig. 1.—Apparatus for Testing Between Atmospheric and Boiler Pressure.

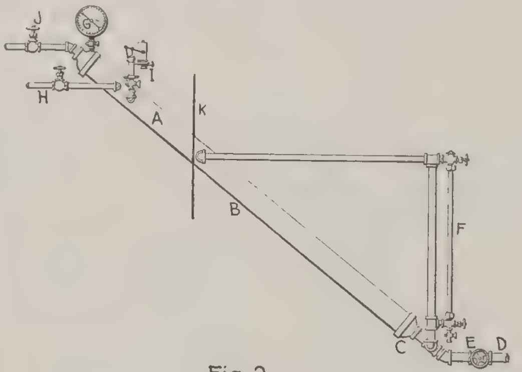

Fig. 2.

Fig. 2.—Apparatus for Testing at Pressures Above Boiler Pressure.

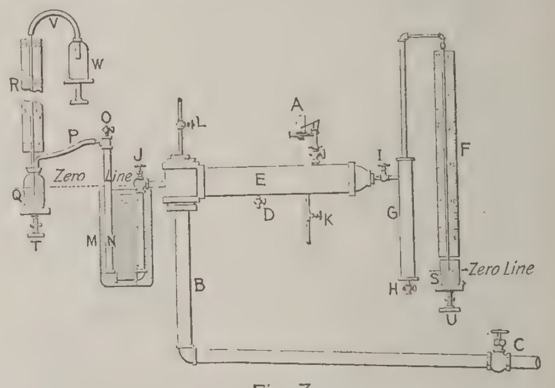

Fig. 3.

Fig. 3.—Apparatus for Use at Pressures Between 15 lbs. Above Atmosphere and Vacuum.

APPARATUS USED IN TESTING INDICATORS AT THE STEVENS INSTITUTE OF TECHNOLOGY, HOBOKEN, N. J.

In the apparatus, arranged as just described, one person adjusts the pressure and traces the lines on the indicator diagram. If so desired, one person may adjust the pressure, and a second trace the lines on the diagram. To arrange the apparatus for this purpose, the blow-off pipe from the valve M is led to a point near the valve K, and a second valve, for adjusting the rate of flow through the blow-off pipe, is placed near the valve K, where it can be operated conveniently by the party who adjusts the pressure. The apparatus which we use is arranged in this way.

In testing indicators with steam pressure, the steam is brought to the maximum pressure to which the indicator is to be subjected; the indicator cock is then opened and closed quickly a number of times, in order to heat the indicator. The steam is then released from the cylinder B, and the atmospheric line is taken after turning the indicator cock to the proper position. In taking the atmospheric line, as well as the lines for any other pressure, the pointer of the indicator is first pressed upward, and then released and a line taken, then pressed downward and released and the line taken, the indicator being rapped sharply with a small wooden stick before taking each line, as has already been explained. After obtaining the atmospheric line, steam is admitted through the valve K, until the pan and weight device is balanced while being rotated. This requires a very fine adjustment, and the line is not taken until there is no tendency for the plug and weight device to either rise or fall.

An apparatus for testing at pressures higher than can be carried on the boilers is represented in Fig. 2. It consists of a pipe A, 4 ins. in diameter and about 8 ft. long, placed in a slanting position, and arranged so that the lower end, from B to C, can be heated by means of Bunsen burners. The pipe D is connected to both a water and steam supply. Water is first admitted through the valve E, until it nearly fills the gage glass F, after which steam is admitted, and the water in the pipe A is heated, and the pressure, as indicated by the gage G, is brought to that of the entering steam. The valve E is then closed, and the pipe A is heated by means of the Bunsen burners until the desired pressure is obtained. The pipe H leads to a plug and weight device, similar to the one shown in Fig. 1. The indicator is placed at I. In the calibration the pressure is brought to slightly above the maximum, and is then adjusted by opening the valve J. The first line taken is for the highest pressure, and the pressure is diminished for taking the other lines of the diagram by adjusting the height of the flames of the Bunsen burners, and the amount of opening of the valve J. Two lines are taken for each pressure, in the same way as described for the aparatus shown in Fig. 1. K is a screen for confining the heat to the lower end of the pipe A. The upper end of the pipe A is encased with a non-conducting covering, to diminish the radiation. An asbestos shield is placed on top of the lower end of the pipe to partly confine the flames of the Bunsen burners and thus render them more effective.

The apparatus employed in testing springs used under a vacuum is shown in Fig. 3. The indicator is attached at A to the top of the horizontal cylinder E. The pipe B leads to a vacuum chamber and pump, and slopes downward, so that no water can collect in it. The amount of vacuum is regulated by adjusting the valve C, leading to the air pump, and by admitting a small amount of air through the pet-cock D. The vacuum gage at F is graduated in inches of mercury and in pounds per square inch. G is a chamber for condensing any steam which may pass through the valve I, and thus prevent it from condensing on top of the mercury in the gage F. The water which collects in G is drawn off through the pet-cock H. The height of the mercury cup S is adjusted by means of the screw U, so that the surface of the mercury is on the same level as the zero point of the scale. There is a straight edge in front of the mercury cup S, at the same level as the zero of the scale, which makes it easy to adjust the level of the mercury to the proper height.

The apparatus may also be used for testing springs at pressures up to 15 lbs. above the atmosphere, the mercury column R being used for this purpose. Where a spring is used for both a slight pressure and a vacuum, the entire calibration can, therfore, be made with the apparatus shown in Fig. 3.

In measuring a pressure above the atmosphere, the valve I is closed and the valve J opened. The pressure of the steam acts then on the water contained in the U-shaped pipe N, and is transmitted through the hose connection P to the water in the upper part of the closed bottle Q. The lower part of the bottle Q is filled with mercury, and when the pressure increases this mercury is forced upward in the column R. The height of the bottle Q is adjusted by means of the screw T, so that the mercury is brought opposite the zero line of the scale, a straight edge being used in the front of the bottle, at the same level as the zero line of the scale, as in the case of the vacuum gage F. In adjusting the bottle Q up and down, the glass tube forming the column moves up and down with the bottle; this tube bears directly against the scale on which the pressures are read. Should the pressure be accidentally raised to such an extent that the mercury will be blown out of the column, the mercury will pass through the rubber hose V into the bottle W.

In testing the indicator, it is first heated by means of steam, admitted through the valve K, until it attains what is considered to be about the average temperature to which it will be subjected in the test. Two lines are taken at each pressure, and all other details in making the tests are the same as have already been described.

---

THE SAFETY OF THE BROOKLYN BRIDGE.

The dangerous overloading of the New York & Brooklyn Bridge, and even the possibility of its early destruction by the loads at present carried by it, have recently been so strongly asserted in the daily press that the emphatic statement of the perfect safety of the great structure by its Chief Engineer and Superintendent, Mr. C. C. Martin, M. Am. Soc. C. E., which we present here, will be of interest to engineers. Mr. Martin's report was called forth by the public clamor following the accident of July 29, 1898 (Eng. News, Aug. 18, 1898), when a blockade of vehicles and trolley cars on the south roadway, combined with the very great expansion of the cables by the excessive heat, caused a slight buckling of the lower chord members of three of the six stiffening trusses. The accident, while trivial in itself, and certainly of no injury to the supporting power of the bridge as a whole, naturally excited the attention of the bridge officials, and caused considerable alarm to many of the more timid passengers over the structure. It was for the purpose of allaying this alarm, and also to provide the revised statement of loads and strains made necessary by the admission of the surface street cars and elevated railway trains of the bridge, that Chief Engineer Martin's report, which we publish here, was made. The report, practically in full, was as follows:

The loads on the bridge at present are made up as follows:

Bridge cars—the trains are made up of four cars; a motor car, which when fully loaded weighs 44 tons; three passenger coaches, fully loaded, weighing 28 tons each, 84 tons. Total weight of train, 128 tons. This equals 256,000 lbs. The trains run at 11.3 miles per hour, and if they run on 45 secs. headway they will be 748 ft. apart from front to front. Hence, the above load will be distributed over 748 ft., giving a load per lineal foot, for both tracks, of 690 lbs.

The trolley cars loaded weigh each 14 tons, or 28,000 lbs., and are spaced 102 ft. apart; hence this load per lineal foot, is, for both roadways, 550 tons.

The load on the carriageways is taken to be two continuous lines of trucks (one on each roadway), each truck occupying 20 ft. and weighing 2.75 tons, 5½ tons on both roadways, or 11,000 lbs.; hence the load from this source is, per lineal foot, 550 tons; total 1,790.

The load on the promenade is taken at 50 lbs. per sq. ft. (although Mr. John A. Roebling says in his original report of 1870, that 30 lbs. per sq. ft. is a maximum load of a moving mass of people). Since the promenade is 15 ft. wide, the load due to this source is, per lineal foot, 750 lbs. Total moving load, per lineal foot, 2,540 lbs.

The length of the main span of the bridge, in the clear, between towers, is 1,545 ft.; hence, total moving load is 3,924,000 lbs, or 1,962 tons.

In 1892, the actual weight of the bridge superstructure was computed for the use of the Board of Experts, which was appointed to advise upon the introduction of the trolley cars upon the bridge, and it was found to be, including cables and suspenders, 5,828 tons. The additional dead load that has been added from time to time is as follows: Additional new track for bridge railway, additional hauling cables and supporting sheaves, electric feed wires and cables, trolley arms, telegraph and telephone wires and cables, trolley tracks and mail tubes, 430 tons. Total dead weight and moving load, 8,220 tons.

To obtain the strain in the cable produced by this load, this weight must be multiplied by 1.7; the strain is thus found to be 13,974 tons. The ultimate strength of each cable is 12,300 tons; or the ultimate strength of the four cables is 49,200 tons. Divide this amount by the strain in the cable, and the factor of safety is found to be 3.52. That is to say, that the whole strain which is now 13,974 tons, must be increased by 35,226 tons to produce the strain of 49,200 tons, which is required to break the cables. Now, since the weight of the structure cannot be materially increased, the whole increase, if it comes at all, must come from the moving load; and since that is 1,962 tons, it follows that the moving load must be increased the number of times found by dividing 35,226 by 1,962 × 1.7, which is 10½, before the limit of the strength of the cables is reached.

The elastic limit of the cables is two-thirds of the breaking strain, or 49,200 × ⅔, which is 32,800 tons.

The total moving load is 1,962 tons, and this would require to be increased 5.6 times in order to strain the cables even to their elastic limit, to which point the metal of the cables may be strained without injury.

With regard to the safety of the anchorages, it is only necessary to say that during the first few years of the use of the bridge both anchorages moved forward at the top about ⅝ in., but there was no movement at the bottom. This movement was due, without doubt, to the compression or settling together of the timbers under the toe of the masonry of the anchorages. During the last eight years, this movement has been about ⅛ in. at each anchorage, so that any strains that have been brought upon them up to this time have produced no injurious effect whatever, and it is not proposed materially to increase the load on the bridge.

With regard to the eight saddles, careful measurements have been made from time to time and the results show that within a year from the time the bridge was opened to public use, they had all moved toward the river about 4 ins. In the 14 years—from 1884 to 1898—they had moved from 1 to 1¼ ins. additional. There is nothing in this movement but what is normal and proper.

In July last, when the outrageously unbalanced loading occurred, the saddles moved toward the river from ½-in. on some to 2½ ins. on others. Those which moved forward at that time are all returning to their normal positions.

With regard to the movement of elevated railroad trains on the bridge, I would say, that the original schedule upon which they were run was approved by this department, and no change has since been made without proper sanction, and every direction from this office has been cheerfully carried out.

With regard to the trolley cars, soon after they entered upon the bridge a tendency was developed to run the cars nearer together than the 102 ft. limit that had been fixed as the distance apart they should run. Without delay the attention of the executive head of the Associated Trolley Companies was called to the matter, and he at once increased the number of inspectors to five on each roadway, and that number were on duty when the buckling took place on July 29. How they came to allow the cars to run so close together as to form a continuous solid line from the point where the obstruction occurred near the Brooklyn tower, over the entire structure to the New York station, I cannot tell, unless their instructions were that they should not run closer to each other than 102 ft., and that they assumed that they might stand in solid line. Be that as it may, the bunching of the cars and the consequent buckling of the lower chord of some of the bridge trusses occurred. This did not in the slightest degree affect the strength or safety of the bridge.

In order absolutely to prevent the recurrence of such a condition of loading on the bridge, instructions were at once given to the inspectors that the cars were not to be allowed to approach each other nearer than 102 ft. In addition, upon your request, the policemen were instructed by the Police Department to aid in enforcing the rule for the trolley cars, and also to prevent bunching of teams on the bridge in case of blockades. I have not the slightest fear that any serious unbalancing of the loads on the bridge will hereafter occur.

In conclusion I beg to say that in my judgment, the bridge is as safe to-day as it ever was, and that is equivalent to saying that it is absolutely safe; that no one need entertain for a moment any fears of its stability. The most careful inspection and supervision by this department of everything pertaining to the bridge has never been relaxed and will not be.

COST OF ASPHALT STREET PAVING IN LOUISVILLE, KY

At the request of the Louisville Board of Trade, Mr. J. H. Pearson, formerly City Engineer of Louisville, recently read before the Board a paper on street paving in that city, in which he pointed out the difference between the lake and the rock asphalt included in bids lately presented for paving. He argued that the two types of asphalt require different treatment to obtain the best results in each case; that climatic conditions must be carefully studied, and that it is folly for a city to apply the same specifications to both classes of asphalt paving. Incidentally he remarks that Louisville has received the lowest bids for asphalt paving of any city in the country; or $15 for a "square" of 100 sq. ft. with a five-year guarantee, and $17.76 with a ten-year guarantee. For original construction, where contractors have to collect from property owners, the bids are higher; or $16.50 and $19.50 per unit square. The portion of the report relating to the detailed cost of asphalt paving contains some useful information, and we reprint in full, as follows:

I base these figures upon the requirements of our present specifications, and take the lake asphalt streets as the example, because I, as yet, have had no means of knowing the cost of the other kind. I should judge, however, that the labor part of the construction of rock asphalt streets, as here constructed, has certainly been more expensive than the corresponding work in lake asphalt streets, judging from the number of laborers employed on each kind.

Our specifications call for an asphaltic cement for lake asphalt streets composed of standard asphalt, 100 parts by weight, and petroleum residue (average) 17 parts by weight. This asphaltic cement must be mixed with sand and limestone powder in the following proportion:

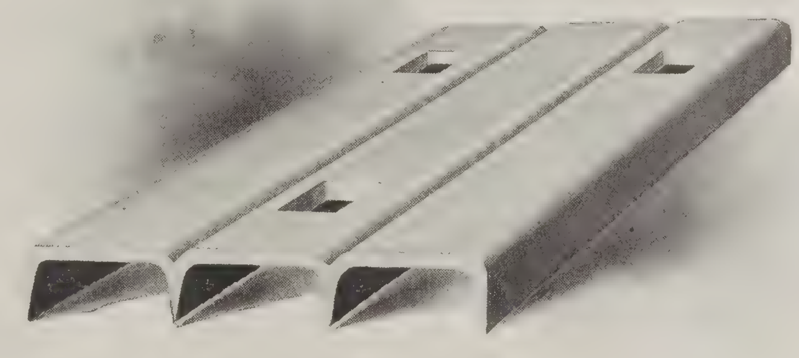
Asphaltic cement (minimum)	14	parts.
Sand (minimum)	81	"
Limestone powder (minimum)	5	"

Figuring this it means:

Refined asphaltum	12	per cent.
Petroleum residue	2	" "
Sand	81	" "
Limestone dust	5	" "

In these proportions a cubic yard of the paving materials contain:

Refined asphaltum	3.24	cu. ft.
Petroleum residue	.54	"
Sand	21.87	"
Limestone	1.35	"
Total	27	cu. ft.
	Or 1	cu. yd.



THE Q. & W. TIE PLATE.
Railroad Supply Co. and Q. & C. CO., Manufacturers.

The wearing surface is required to be 2½ ins. thick. Therefore this cubic yard will cover 129.6 sq. ft. of surface, equal to 1.296 squares of surface as we measure, using 100 sq. ft. as one square. Make a note, that for this over one and a quarter squares of surface only 3.24 cu. ft. of refined asphalt is required, while the other 23.76 cu. ft. are all home products. One square of asphalt street work with us means also one square of concrete base 6 ins. thick. To cover 1.296 squares of surface with concrete base 6 ins. thick requires 2.4 cu. yds. of concrete. Also one square of surface requires one square of binder 1½ ins. thick, requiring 15 cu. ft.

Assuming the contract price of one square of street to be $18, then 1.296 squares would cost $23.33 by contract. Eighteen dollars per square has been, in round numbers, about the bid for reconstruction of streets.

Concrete made with Louisville cement can be laid at a fair profit for $3 per cu. yd. Thus the 2.4 yds. required would cost $7.20, leaving $16.13 out of the $23.33 for the cost of binder and wearing surface. The 15 cu. ft. of binder, assuming broken stone to cost $1.25 per yard (the contractor usually gets this stone off the old street at a cost of only about 50 cts. per cubic yard for breaking and hauling) the cost of 15 cu. ft. of stone would be 60 cts., and the asphaltic cement at 13½ cts. ($30 per ton) per gallon, or cost for the nine gallons required, making a total cost of $1.86 for the binder. Subtracting this from the $16.13 leaves $14.27 for the cost of the wearing surface alone.

Assuming refined asphalt at $30 per ton (the price you or I would have to pay for it, but much more, I think, than the contractor pays for it for street work), is equal to 22.9 cu. ft. per ton, or $1.31 per cu. ft. It requires 34 lbs. of petroleum residue for the 1.296 squares of street worth 5¼ cts. per gallon of 8 lbs. (as the Standard Oil Company say), or 4¼ gallons, costing 22⅓ cts. This is equivalent to 40 cts. per cubic foot.

Sand at $1.08 per cubic yard equals 4 cts. per cubic foot, and limedust at 60 cts. per barrel of about 6 cu. ft. costs 10 cts. per cubic foot. The wearing surface mixture then for this 1.296 squares costs total as follows:

Asphalt, 3.24 cu. ft., at $1.31	$4.24
Petroleum residue, .54 feet, at 40c	.21½
Sand, 21.87 feet, at 4c	.87½
Limestone powder, 1.35 feet, at 10c	.13½
	$5.46½

Deducting this from the $14.27 remaining out of the $23.33, after allowing for cost of concrete and binder, we have $8.80 for cost of labor and profit.

Labor is supposed to cost as follows:

Mixing	4 cts. per sq. yd.
Hauling (estimated)	2 cts. per sq. yd.
Laying	6 cts. per sq. yd.
	12 cts. per sq. yd.
	Or 1⅓ cts. per sq. ft.

The 129.6 sq. ft., therefore, costs for labor $1.73, which deducted from the $8.80 leaves $7.07 for the profit to the contractor to construct 1.296 squares of streets, which is equivalent to a profit of $5.45 per square out of the $18 per square assumed as bid or about 30%. (In these hard times a very fair profit such as few of you in your business are able to make.)

These figures show that the actual cost of lake asphalt streets is about $12.55 per square of 100 sq. ft. (there are reasons why this cost is really less, but it is very difficult to get reliable data from the companies who use it, and they are the only source for such data), and therefore, streets of this class it would seem to us taxpayers might be built cheaper than about $18 per square and still allow reasonable profit of say 15%. My own opinion, based on what I have read and learned, is that such streets can be laid without loss (perhaps no profit) at $10 or $11 per square.

As to the cost of rock asphalt streets, I think, $15 per square with a good guarantee, is about as low as we can reasonably expect good streets to be built, and I do not believe the profit is more than 10%, or possibly 15% at this price. I believe good rock asphalt streets are superior to lake asphalt streets, but not enough so to warrant discarding the latter, and they have the advantage of costing less for repairs than the lake asphalt besides having other small advantages not necessary to mention.

A GROOVED TIE-PLATE.

A new form of tie-plate for railway track is now being introduced which combines the grooved face of the Wolhaupter plate with the outside longitudinal flanges of the Servis plate, thus effecting a combination of the strength and lightness of the former with the secure attachment to the tie of the latter. During the past two years about 40,000,000 tie-plates of these two types have been sold, each having its special advantages, and in the new plate the aim has been to include these advantages. The plates are of the form shown in the accompanying cut, and are made in two sizes, 4¼ and 5 ins. wide.

As the special features are covered by patents owned by two companies, a new company has been organized, under the name of the Q. & W. Co., of which Mr. Willis S. Jones is General Manager, with office in the Owings Building, Chicago, Ill. The sole licensees authorized to manufacture and sell the Wolhaupter, Servis and Q. & W. tie-plates, are the Railroad Supply Co. and the Q. & C. Co., both of Chicago.

WORK OF THE FIRST REGIMENT OF U. S. VOLUNTEER ENGINEERS IN PORTO RICO.

On the evening of Dec. 8 the officers of the First Regiment U. S. Volunteer Engineers gave a complimentary dinner to Colonel Eugene Griffin, the commander of the regiment, at Sherry's, New York city, and presented him with a silver loving cup.

In his speech of acknowledgment Col. Griffin described the inception and formation of the Brigade of Engineers, and particularly the First Regiment.

Col. Griffin is a graduate of West Point, in the class of '75. He entered the Corps of Engineers and afterwards resigned. At the outbreak of the war he felt that he was again called into actual service. In his position as Vice-President of the General Electric Co., in which capacity he was in close contact with the engineering profession of the country, he naturally turned towards the engineering side of the coming struggle. Mainly through his efforts, Congress authorized the formation of a Brigade of Engineers, and Col. Griffin was given command of the First Regiment. It was principally to the character and work of the men composing this regiment that his remarks referred.

In the course of his address, Col. Griffin outlined the actual engineering work performed in Porto Rico, as follows:

> A detailed topographical survey of the main highway from the sea, through Ponce to Aibonito; a survey of the Aibonito Pass, showing the locations of the Spanish batteries and intrenchments; a detailed hydrographical survey of the harbors of Ponce and Guanica; the rebuilding of the fine masonry bridges destroyed by the Spaniards on the military road which crosses the island; the building of a dock and commissary storehouses; the setting up of an ice plant and refrigerating plant for the General Hospital at Ponce, and the construction of buildings for this purpose; the building of a concreted high level reservoir for the hospital, and the completion of the water supply system, including setting up the pumps, laying the pipes, etc.; the partial construction of Fort Capron on the heights overlooking the entrance to Guanica harbor, and the building of a road up the side of the mountain leading to the fort; the laying out of the first National Cemetery in Porto Rico, and many other minor works.

From the time the first detachment of recruits arrived at Peekskill, N. Y., on June 23, until the regiment returned to New York, on Nov. 24, was 154 days. The start was made with 1,097 men and 48 officers, while 857 men and 47 officers returned, 13 men and one officer died, 61 men were left in the hospitals at Ponce and Guanica, the remainder having been discharged or sent home on sick furlough at different times.

In referring to the personnel of the regiment, Col. Griffin said:

> It is my deliberate judgment that engineers, including tradesmen, will make better soldiers than any other class of men, and by soldiers I mean all that the word implies, men trained in drill and marksmanship, able to care for themselves in the field, and to make long marches and to meet the enemy under all conditions, either offensively or defensively. The very nature of the training and daily lives of carpenters, blacksmiths, plumbers, lumbermen, railroad men, steam engineers, electricians, masons, etc., is a preparation for the life of the soldier.

THE CALORIFIC POWER OF COALS IN RELATION TO THEIR PROXIMATE ANALYSES.

In the discussion of the paper of Messrs. R. S. Hale and H. J. Williams, on "The Calorific Power of Weathered Coal," at the New York meeting of the American Society of Mechanical Engineers, Mr. William Kent presented a written discussion, from which we abstract the following:

The authors have compared their results with the curve which I plotted from the results of Mahler's calorimetric work, and published in Vol. I. of "Mineral Industry," in 1890, and also in 1897 in Vol. XXIV. of the Transactions of the American Institute of Mining Engineers, in connection with the discussion of Profs. Lord and Haas on American coals. This curve has frequently been referred to by recent writers, and has now fairly established its validity within the limits claimed for it. I present the curve herewith, with a slight modification which later studies have made advisable.

A table derived from the curve is as follows:

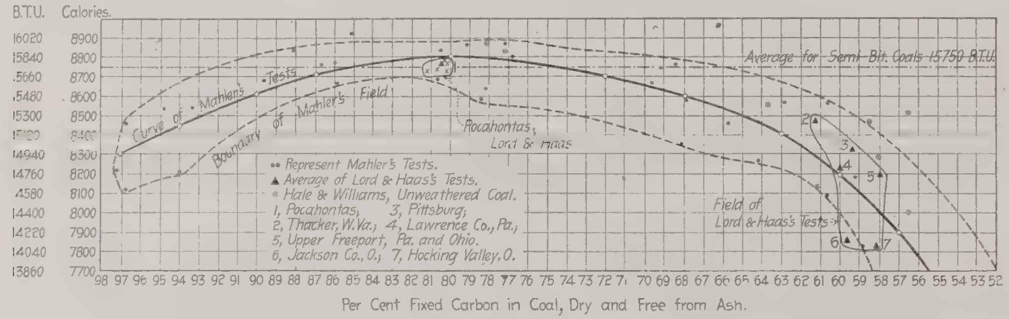
Approximate Heating Value of Coals.

Fixed carbon in coal.*	Heating value.		Fixed carbon in coal.*	Heating value.	
	Calories.	B.T.U.		Calories.	B.T.U.
97%	8,300	15,940	63%	8,400	15,120
94%	8,450	15,210	60%	8,200	14,760
90%	8,600	15,480	57%	7,900	14,220
87%	8,700	15,660	55%	7,700	13,860
80%	8,800	15,840	53%	7,400	13,320
72%	8,700	15,660	51%	6,900	12,420
68%	8,600	15,480			

*Dry and free from ash.

The original claim made for the curve was as follows: "Knowing the percentage of fixed carbon in the dry coal free from ash, we may, in the case of all coals containing over 58% of fixed carbon, predict their heating value within a limit of error of about 3%."

In 1897 a study of Lord and Haas's work led to the following statement: "Excluding coals which have below 58% of fixed carbon in the combustible, the variation of any one of Lord and Haas's coals from the Mahler line does not exceed 320 calories (576 B. T. U.), or about 4%. Taking the average figure for each class of coals [There were seven classes, 39 coals in all, viz.: Pocahontas, 5; Hocking Valley (O), 5; Pittsburg, 7; Middle Kittanning (Pa.), 7; Upper Freeport (Pa. and O.), 11; Mahoning (O.), 1.] it falls in all cases within the limit of 3%. Taking into consideration the fact that the reported percentage of fixed carbon is very apt to be 2% or 3% in error, I am disposed to hold my original conclusion, at least until a larger series of tests may show that it should be modified. It is to be observed, however, that the Mahler line falls rapidly with percentages below 62% of fixed carbon; and it is therefore to be expected that below this point there will be a greater range of variation in the heating value than above it. When the volatile matter exceeds 38% an increasing proportion of it is exygen; and the relative proportion of oxygen in the highly volatile coals varies in the coals of different districts, as is shown by Lord and Haas's analyses. Thus the Upper Freeport coal averages only 9.58% of oxygen (in coal dry and free from ash), while the Hocking Valley coal averages 16.10%, although both coals have the same percentage of fixed carbon, namely 58%. Full credence, therefore, is to be given to the conclusions drawn from Lord and Haas's tests that, when the fixed carbon is less than 62% of the combustible, each class of coal has a law of its own, and coals of any one class may differ in heating value from coals of another class containing the same percentage of fixed carbon to an extent as great as 5%, as in the case of the Hocking Valley and Upper Freeport coals."



RELATION OF THE CALORIFIC VALUE OF COALS TO THE PER CENT. OF FIXED CARBON IN THE COMBUSTIBLE.

A study of the results now presented by Messrs. Hale and Williams shows:

(1) That all the calculated or calorimetric results of coals containing more than 59% of fixed carbon in the combustible, weathered or unweathered, are within the stated limit of the curve of 3%, with the single exception of the result calculated from the analysis of the weathered coal "D." This exception is evidently due to an error in the analysis. The aproximate analysis shows an increase of fixed carbon by weathering of 3.68%, referred to combustible; while the ultimate analysis shows a decrease in total carbon of 0.99%. The figures are incompatible.

(2) The coals containing less than 59% of fixed carbon show in most cases a wide divergence from the curve, tending to confirm the conclusion drawn from the work of Lord and Haas that among the highly volatile coals each class of coals has a law of its own.

SPECIAL WIRE ROPES FOR HOISTING PURPOSES.

In the ordinary construction of wire ropes a the strands are built up of wires of circular cross section, and the outer wire of each strand takes the wear in coiling and uncoiling, so that small wires are liable to be soon worn through, while heavier wires have a tendency to fracture when the wear by abrasion has reached a certain limit. In the two styles of wire rope shown herewith, each strand has a core or central wire of special form.

The strands of the "flattened strand" rope, Fig. 1, are built up of circular wires around a flattened central wire, so that the strand is approximately oval in section, and several of the outer wires take the wear and transmit the pressure to the flattened wire. In fact, the rope is said to have 150% more wearing surface than ordinary rope, thus tending to increase its life, while its greater smoothness of surface reduces the wear upon the pulleys and sheaves. It is also said to be exceedingly flexible, with freedom from any tendency to spin or kink.

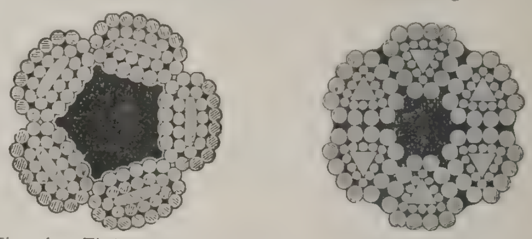


Fig. 1.—Flattened Strand Rope. Fig. 2.—Triangular Strand Rope.

Wire Ropes for Hoisting.
A. Leschen & Sons' Rope Co., Makers.

This style of rope is being extensively used for passenger and freight elevators in office buildings, warehouses, stores, etc. The ropes in the passenger elevators of the Decker Building, New York, have been in constant use since April, 1896, and are still in good condition, though the owner of the building states that they have already lasted twice as long as the ropes formerly used. All the elevator ropes are made of special Swedish iron wire. The ropes used for this purpose are principally ⅝-in. and ¾-in. diameter, weighing about 67 and 96 lbs. per 100 ft., and having a breaking strain of 6 and 9 tons, respectively. The same style of rope is also used for haulage and power transmission.

The "triangular strand" rope, Fig. 2, has the central wire of each strand made of triangular section, with several wires bearing upon the outer face of this wire. This rope is said to have the same advantages in smoothness and flexibility as the "flattened strand" rope. It is being extensively used for heavy hoisting in mines, on derricks and on inclines, etc., for which purposes it is made of Hercules brand wire or of crucible steel wire.

Both these ropes are manufactured by the A. Leschen & Sons Rope Co., 920 North Main St., St. Louis, Mo., and we are indebted to the makers for the above particulars.

AN ILLUSTRATION OF THE INFLUENCE OF IRRIGATION ON SOIL TEMPERATURE.*

By L. G. Carpenter and R. E. Trimble.†

The control which irrigation gives of soil conditions is well known by students of irrigation and is more or less realized by farmers in the arid regions. The extent of this influence is, however, not often recognized, and it is rarely that an illustration as clear as was shown by the soil temperature observations during August, 1897, is to be obtained. In this case our soil thermometers being placed in the grass plat were so situated that the irrigation of the lawn flooded, to a depth of some inches, the ground where the instruments were placed, and the irrigation was continued long enough to saturate the ground underneath. The temperature at a depth of 6 ft. had been nearly uniform at 62° F. for a number of weeks before the date of irrigation on Aug. 12.

With the application of the water it is noticed that the temperature immediately rises, reaching a temperature of 71° almost immediately after. The temperature fell almost immedately after the irrigation, so that during the next three days it had fallen to 64½°. On Aug. 16 the irrigation was repeated, and this time the effect of this added to the effect of the first was to increase the temperature to 75½°. The temperature dropped rapidly to 69°, and then dropped gradually, not again reaching 62° until October. The effect of irrigation on the plat of ground and its vicinity was felt for more than a month.

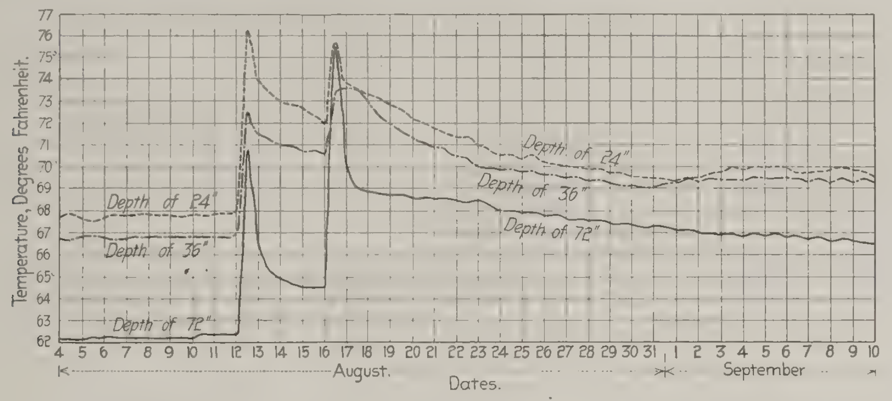
The effect on the temperature at 2 ft. and at 3 ft. in depth was much the same. At the first irrigation the temperature at 2 ft. was increased over that at the lower depths. At the second irrigation the effect on the deep thermometer was almost as great as upon the 2-ft. thermometer. For the depths less than 2 ft., the diurnal fluctuation is marked, and as the corresponding curves confuse the diagram, they are omitted. The shallower thermometers also show the cooling effect from evaporation so much that their temperatures fell below the deeper ones. In view of the influence which temperature has upon the growth of plants, the importance of the fact shown in the diagram is apparent. Evidently the irrigator can increase the temperature of the soil by application of water of proper temperature. It is also evident from corresponding observations at the shallower depths, that the cooling effect on the sail from evaporation may be considerable.

---

*Extract from Bulletin No. 49, "Meteorology of 1897," of the Agricultural Experiment Station, Ft. Collins, Cal.

†Meteorologists and Irrigation Engineers to the Station.

But as the application of water warmer than the soil will carry heat down into the soil and raise the temperature in spite of the cooling effect of evaporation, so an application of colder water has the opposite effect and chills the soil, both by the direct abstraction of heat and from evaporation.



THE EFFECT OF IRRIGATION ON SOIL TEMPERATURES.

The diagram is here given because of its suggestiveness, and to call attention to the influence of the temperature of the water used. It also suggests a reason why most farmers find it undesirable to irrigate early in the spring and why fall irrigation is sometimes so advantageous irrespective of the need of moisture.

The importance of considerations of this kind, illustrated by the diagram, will be considered more extensively when the observations on irrigation and on soil temperature are published.

◆

MUNICIPAL OWNERSHIP OF WATER-WORKS at Winnipeg, Man., seems likely to be effected soon, it being reported that the London bondholders have accepted the offer made by the city to pay $237,500 for the plant of the Winnipeg Water-Works Co.

◆

THE EXPIRATION OF THE TELEPHONE FRANchise of the Duluth & Superior Telephone Co., Duluth, Mich., occurs on March 9, 1898, and the city of Duluth has decided to advertise for bids for furnishing telephone service for a term of years. A percentage of gross receipts wil be demanded and a rate lower than that heretofore given, together with a certain number of free instruments and a differential in favor of residence telephones. The present company is one of the Bell corporations, and this week has reduced house rates from $50 to $36 a year.

◆

THE LOWEST BID for garbage collection and disposal at Philadelphia for the ensuing year was from the American Product Co., $358,000. The contract price for 1897 aggregated $327,100, the above company now having the contract for three districts, and treating the garbage by the Arnold process, while the Phildelphia Incinerating Co. now has the contract for the two remaining districts, and burns the garbage in Smith-Siemens furnaces. The latter company did not bid this year and there was scarcely any competition. That there was little competition is not surprising in view of the fact that the contract is for but one year, and has been divided between much the same interests for several years back.

◆

THE NEW YORK CONTRACT FOR SNOW REMOVAL was awarded, on Dec. 9, to Bart Dunn, at 30 cts. per cu. yd., or the lowest price since the contract system was inaugurated. The bond required is $100,000. The other four bids ranged from 30⅓ to 38 cts. per cu. yd.

◆

THE WARING FUND has now reached $77,555, the later contributions ranging from $100 down. The contributions for Dec. 9 aggregated $7,553, and the Chamber of Commerce Committee is now assured of the speedy receipt of the entire $100,000 asked for.

◆

CREOSOTED WOOD PAVING BLOCKS 4 ins. deep, on 6 ins. of concrete, have just been recommended to the Kensington Vestry of London, by Mr. Wm. Weaver, Surveyor, according to the London "Contract Journal." It seems that some of the ratepayers were anxious to extend the use of wood paving in place of the present macadam. Under existing rules this can be done, Mr. Weaver states, only when the maintenance of the macadam road costs 20 cts. per sq. yd. per year, "without scavenging and watering." This condition prevails only under "very severe traffic." To reduce the standard of conversion without an increase in the expenditure, 4 instead of 5-in. blocks are recommended. Mr. Weaver states that the reduction of the depth of the blocks from 6 to 9 ins. to 5 ins. in 1883 has saved the Vestry about $60,000. In 1889 two streets were paved with 4-in. creosoted deal blocks, regarding which Mr. Weaver says:

> After nine years wears, the road surface is in nearly perfect condition, and only a very small amount has been spent on repairs during the nine years; one-fifth of a penny per superficial yard for last year, and a half-penny per yard for the preceding year.
>
> The road is wearing thin and the wood will have to be renewed in 1900. The traffic on these streets is very heavy, having increased on one of the streets from 1,429 vehicles, or 42 per ft. width in 1888, to 2,950, or 87 per ft. width in 1898. The wood paving cost about $2.25 per sq. yd. in 1888 and the renewal is estimated to cost about $1.70. Mr. Weaver concludes that wood paving consisting of creosoted deal blocks, 4 ins. deep, laid on 6 ins. of Portland cement concrete, might advantageously be substituted for macadam where the maintenance charges on the macadam are 12 cts. per sq. yd. The cost, including capital charges, would be slightly increased, but this would be offset by the superior character of the paving.

◆

CRUDE OIL ON COUNTRY ROADS has been given a trial at Keokuk, Ia., with very gratifying success, according to a report presented by Major M. Meigs before the Missouri Good Roads Association on Dec. 3. The plan followed is to sprinkle ordinary dirt roads when dry, especially in low places where mud is usually formed. The oil forms a water-proof crust, keeps out the water and prevents the formation of dust and mud. It is claimed that a barrel of crude oil costing about 90 cts. is sufficient to cover a strip of road 100 × 12 ft.

◆

A SURFACE CONTACT STREET RAILWAY of American design and construction has been recently installed at Monaco, France, by the French representative of the General Electric Co., of Schenectady, N. Y. According to the English "Railway World," this road extended from the city to the Casino at Monte Carlo, a distance of about three miles. The track, 3 ft. 3-in.-gage, is of 73-lb. girder rails, using rod cross braces and wooden sleepers. The principal grade is 1,320 ft. long, with a rise of about 1 ft. in 12. Between the tracks are two rows of studs, or contact buttons, alternating in position, which connect with automatic switches grouped together in manholes placed along the line, thus putting all operating parts where they can be inspected. On the car are storage batteries, and contact shoes that slide across the studs, operate the automatic switches and thus connect the car motors with the main feeders. The cars used are 27½ ft. over all, with a 19-ft. body. They are divided into first and second-class compartments, are equipped with G. E. 53 motors, Brill trucks, electric brakes, and other American devices.

◆

THE GENERAL ELECTRIC CO. has obtained the contract to build eight electric locomotives and other equipment for the tunnel division of the Paris-Orleans Railway, in Paris. The contract was won against strong English and European competition. The General Electric Co., some months ago, received the contract to supply 28 similar locomotives to the new Central London Underground Railway Co.

◆

ELECTRIC LIGHTS FOR LIGHT-HOUSES at various points on the Great Lakes will be tried by the U. S. government. It is understood that the first experiments will be conducted at Marquette, Mich., where a breakwater extends out into the lake about 3,000 ft. During storms waves frequently sweep over this making the trip to light the ordinary oil lamp extremely dangerous. The plan to be adopted includes the placing of a submarine cable along the top of the masonry, and the use of a 50-c. p. stereopticon incandescent lamp, which will be controlled from the shore.

◆

A UNIFORM SMALL-ARM CALIBER and cartridge is the question to be considered by a board appointed by the Secretary of War, and now in session in New York. This uniform caliber should be adopted for all small arms and machine guns used by the Army, the Navy and the Marine Corps. The report will not be made public.

◆

TWO LARGE TRANSPORTS for the use of the Navy are asked for by Secretary of the Navy Long, in a letter to Congress requesting the insertion of this item in the Naval Appropriation bill. The vessels called for would be twin-screw, steel ships, of about 7,000 tons displacement, with a maximum speed of 18 knots and to cost not more than $1,250,000 each. Such a transport would carry 1,200 men and their officers, with all regimental supplies, wagon trains, ammunition, hospital stores, etc. Distilling and refrigerating apparatus would be supplied. The argument for the building of special transports is that existing merchant ships can not be properly adapted to this purpose. All horses would be transported on separate ships of the usual type. As the Army is strongly opposed to giving up the transport of troops, it is expected that this request will cause considerable controversy in Congress. Inspector-General Breckinridge, in his annual report, favors, however, the naval control of the transport service, and this is in accordance with foreign practice.

◆

A SPECIAL FLAG for the Coast and Geodetic Survey vessels was first adopted in launching the survey vessel "Pathfinder" at Elizabethport, N. J., on Dec. 7. This flag has a blue field carrying a white circle in the center with a red triangle in this circle.

◆

THE TENNESSEE RIVER IMPROVEMENT ASSOCIAtion held its annual convention in Chattanooga, Tenn., recently, Gen. Joe Wheeler presiding. A memorial to Congress was presented asking that a complete survey be made of the whole Tennessee River system, and especially for the 100 miles between Bridgeport and Decatur, and the section between Florence and Decatur. The most prominent work now in progress is the Colbert Shoals Canal. The memorial concludes by asking Congress to grant the $2,065,000 recommended by the officers of the Engineer Corps.

◆

EXPRESS COMPANIES doing business in the state of New York will be placed under the supervision of the State Railroad Commission if a bill prepared by the Merchants' Association of New York is successful. A table published by the association giving comparative freight and express charges from New York city to the principal towns in the state shows that the express charges per 100 lbs. are from 2½ to 4 times the amount of the corresponding freight charges. The association fails to state that the more prompt transmission of goods by express and their free collection and delivery justifies a considerably higher charge for express than for freight. It is doubtless true, however, that express charges, especially on small weight packages over long distances, are much higher than necessary to give the companies a fair return. It is also to be remembered that the capital of express companies represents a trifling actual investment, as compared with railway companies.

◆

"CARBOLITE," AN ALLEGED NEW CARBIDE is discussed editorially in the "Engineering and Mining Journal" of Dec. 10. It is described in the patent of Herman L. Hartenstein, as calcium-aluminum-silicon-carbide, with the formula Al_4, C_3, SiC, CaC_2. The inventor describes a process of making it by taking blast furnace slag directly from the blast furnace into a converter, impregnating it with pulverized coke by means of a gas blast, and sending a powerful current of electricity through the mass, thus producing the carbide. "The Engineering and Mining Journal" describes the chemical reactions, showing that the product would be a very poor substitute for calcium carbide in the manufacture of acetylene, and states that it is doubtful if it can be made without infringing on existing patents. It says: "The Hartenstein patents are of a kind that ought to be shunned by investors, although we understand that considerable money has already been laid out for their exploitation."

BOOK REVIEWS.

CANALISATIONS ELECTRIQUES.—Aerial Power Lines. By R V. Picon, Engineer of Arts and Manufactures, Paris; Gauthier-Villars, Quai des Grands-Augustins 55, Paris, France. Paper; 4½ × 7⅜ ins.; pp. 172; 86 illustrations; 18 tables.

This is another volume of the "Encyclopedie Scientifique des Aide Memorie," a series of publications upon scientific subjects published under the direction of M. Leaute. It is the third of a series by the same author, all on the distribution of electricity, the first two volumes pertaining to isolated installations and central stations. This volume, as stated in the title, treats of what may best be described as line construction, and, as would be expected, considers conductors, wires and cables; insulators for low and high potentials; insulator pins, brackets, cross-arms; poles, anchorages, metal poles and the other line materials.

The book is divided into four parts, Line Materials, Erecting the Line, and Tables and Calculations, which headings suggest in a general way the contents. No attempt is made to exhaustively treat the subject, but enough is given to make the book interesting and instructive reading.

DIFFERENTIAL AND INTEGRAL CALCULUS FOR TECHNICAL SCHOOLS AND COLLEGES.—By P. A. Lambert, M. A., Assistant Professor of Mathematics, Lehigh University. The Macmillan Co., New York and London. Cloth; 12mo.; $1.50.

Of the making of books on calculus there is no end. The present work may be useful to a teacher of mathematics to have in his desk as a reference book along with a dozen other works on the same subject, but we think few teachers would care to substitute it as a class book for the one they have been using. The author uses the method of limits instead of the infinitesimal method, and his discussion of limits is far from being as clear as that of some other writers. His style is in general too concise for clearness. The book contains a great number of problems, but there seems to be no good reason why the answers to these problems should not be given.

DAS WASSERWESEN DER NIEDERLANDISCHEN PROVINZ ZEELAND.—Von Friedrich Müller, Königlisher Regierungs-Baumeister. Mit 10 Tafeln in Steindruck, enthaltend 133 abbildungen, sowie 121 abbildungen im text. Berlin, 1898, Wilhelm Ernst & Sohn. Boards; 10½ × 7 ins.; pp. 612, and atlas of ten plans, 11⅝ × 10¼ ins. 36 marks.

This is an exhaustive study of the proposed and actual reclamation of the Province of Zeeland, in the Netherlands, including the region covered by the mouth of the River Schelde. The author begins with the geological formation and traces the processes which have resulted in the peculiar configuration of this part of Holland; he traces the elevation of the "polders" reclaimed from the sea by dykes, and by reproductions of old maps, dating back to the 6th century, he shows the successive encroachments of the sea and the efforts made to beat it back, as nearly as the somewhat uncertain mapping of these centuries will permit. Views of old towns and cities, taken at different periods, show their gradual destruction by the sea, or their apparent removal from the sea coast by sand accumulation. Modern reclamation work is then taken up in detail showing mattrass protection, fascines, dyke-building with piles and stone, tools used, etc. The sand-dunes and the beach are separately treated, and the means described for stopping the advance of the one and arresting the destruction of the other The cost of work of this character is given at very considerable length, and the several systems adopted are compared. Pier and breakwater building follow, and individual examples are fully illustrated and described. A chapter is devoted to the organization, personnel and regulations of the Waterstaat, or department of the government having this work in charge; the duties of the engineer and other officials are defined, and the adopted program is laid down for the several sections of Zeeland and the methods indicated by which the work is to be carried on. The construction of ship canals and the maintenance of communication with the sea, for the important towns, conclude the volume. Mr. Müller's work is both a treatise on the natural conditions existing in Zeeland, and a hand-book of methods adapted for dealing with them.

SEWERAGE; THE DESIGNING, CONSTRUCTION AND MAINTENANCE OF SEWERAGE SYSTEMS.—By A. Prescott Folwell, M. Am. Soc. C. E. New York: John Wiley & Sons. London: Chapman & Hall, Limited. Cloth; 6 × 9 ins.; pp. 372; 24 tables and 48 illustrations. Price, $3.

A book on both the separate and combined systems of sewerage, based on recent American practice, and noting the most instructive features of foreign work, has long been demanded in this country. This volume goes far towards filling the conditions named, as far, probably, as could be expected within the limits of 350 pages. More extended treatment at some points would be welcome to many, but most of the information the author might have added can be obtained elsewhere. Thus, only an outline of the principles involved and the methods available are given under sewage disposal by other methods than dilution, the author stating in effect that a full presentation of the subject would double the size of the volume, besides going over ground already "most ably treated by others." This is an extreme example, however, as most of the other phases of sewerage engineering are presented with sufficient fullness to enable an engineer not familiar with sewerage design and construction to solve all the ordinary and many of the special problems that arise in practice. For the most part, the author could have gone into the subject more fully only by giving more of the data on which his conclusions are based and more examples of actual practice in the design of sewerage systems. Sewage pumping machinery might have been given more space than five pages with great advantage. It is true that pumping is not often necessary, and that reference may be had to several books on pumping engines, but pumps must be used much more frequently in the future than in the past, and if the student is to be referred to other books on this subject, so he might be for some of the facts regarding the hydraulics of sewers, though with less propriety, we admit. Certainly it seems a pity that the reader cannot learn from the book what sort of a device a Shone ejector is, except by inference from its name and the statement that compressed air is used to operate it. One reading about the device for the first time would like to know how it works.

Under sewer assessments, reference, at least by title, might well have been made to the Brockton report on this subject and to the symposium recently published in the "Journal of the Association of Engineering Societies," two valuable sources of information.

The volume is divided into three parts: (1) "Designing"; (2) "Construction"; (3) "Maintenance." The last two divisions are intended to be practical, as they should be, and they are very satisfactory in this respect. They give the impression of having been written by a person recently connected with actual works, who has at the same time noted the experience of others. The accompanying sketches aid greatly in giving a clear idea of the methods described.

Regarding the book as a whole, it may be said that it is a comprehensive presentation of the subject, well up to date, written in a clear, logical and attractive style. Two praiseworthy features noted at various points are good judgment in weighing evidence and an absence of crotchets and hobbies. We are glad to see that the book has an index, and one that is well above the average.

TRAITE PRATIQUE DE LA CONSTRUCTION DES EGOUTS. Jules Hervieu. Paris, 1897: Baudry et Cie.

The title of this book is misleading, for it is essentially with the sewers of Paris that the author deals. But concerning these, he goes into considerable detail, stating briefly the underlying principles of their design, but avoiding long mathematical discussions or, indeed, any great elaboration of the principles involved in the general design of sewerage systems. From the title one would look for something more comprehensive in scope. Nevertheless, the volume is well worth the perusal of American engineers, for it contains the results of the accumulated experience of a corps of highly trained municipal engineers for some half a century. The book is divided into two parts, the first treating of the general design of sewers and accessory works, and the second describing their construction and giving estimates of cost. There are, moreover, sixteen appendices, which contain, among other things, samples of specifications, time books, etc., standard sections of the Paris sewers, details of the calculation of quantities, and a discussion of run-off.

The American reader will note the care with which provision is made for what many are apt to consider unimportant features of such work—matter which our city officials are accustomed to leave to the caprice (or, perhaps, the good sense) of the party in control. The following are a few of the many particulars in which the practice in Paris is seen to differ from that in this country: First, as to design, dead ends are generally avoided and where two sewers cross at different levels steps connect the two for the convenience of the workmen. The use of pipe sewers is limited to a comparatively small number of unimportant laterals, most sewers being built of stone of the well known sections with cunette and banquette. They are sufficiently large to carry water and compressed air pipes, electric conduits, etc., as well as to permit cleaning by manual labor without inconvenience. Vassy cement appears to be quite generally used except for a coating of Portland cement plaster, from 1 to 3 cm. in thickness, applied to the interior surfaces. The extrados of the arch receives a coat of Vassy cement mortar, 2 cm. in thickness. This, being "particularly exposed to injury by street urchins who frequent the works after the workmen leave, it is well to stop work some hours before the end of the day, so that the mortar may then, having acquired sufficient consistence, be covered by a protecting layer of earth at least 0.4 to 0.5-m. in thickness" At least fifteen days before beginning the work, notice is served, the Prefect of Police making known its nature and location, and indicating the proper route to be taken by street traffic during construction. "After obtaining authority to close the street, individual letters are addressed by the engineer of the municipal service to each abutting property-holder, advising him of the dates of the beginning and termination of the work; this notice is to allow those interested, especially manufacturers and tradesmen, to make every necessary provision in time to avoid the sudden interruption of traffic."

Attention is being directed more and more to the loose way in which many American cities have virtually abandoned the control of their most valuable streets by the award of franchises to electric light and other corporatins; and it is therefore of particular interest to note that in Paris subways and other structures, the use of which is permitted to concessionaires, are not allowed in any way to hamper the city in the construction of its sewers.

During the process of excavation compressed air or other pipes, controlled by concessionaires, which interfere with the work, are removed and subsequently replaced by the latter without charge to the city, on the grounds of public necessity. It is provided, also, that when articles of value, coin, medals, etc., are found on the work, they shall become the property of the administration, but that the finder shall receive as a reward one-half the value thereof. What proportion of such articles of value fail to reach the coffers of the administration is not stated. It is customary in some American cities, in order to avoid unbalanced bids, to fix unit prices for certain classes of work or material, the amount of which is a matter of particular uncertainty. In Paris, probably for the same reason, the city assumes the cost of pumping required to drain the trench. "As long as the depth of water at the bottom of the excavation does not exceed 10 cm. the contractor shall, without further allowance, drain the water to the pumps, the cost of pumping remaining solely as a charge against the administration; the works required to ensure drainage when the depth exceeds 10 cm., rests, on the contrary, entirely at the expense of the administration." In the construction of arches of small diameter, two half centers abutting at the crown are used. They are supported by props, and in this way "put" holes in the masonry are avoided. In exceptional cases, gas pipes are permitted to cross through the sewer arch, but cast-iron sleeves are then provided, which completely encase the portion of gas pipes so included.

Particular care is given both in the design and execution of the work to afford every convenience and safeguard to the laborer. "When the excavated earth is infected or polluted by excrementitious matter or infiltrations which are liable to endanger the public health, or even to alarm the inhabitants of the neighborhood, the contractor shall proceed, at his own expense, to sprinkle and disinfect such earth and the sides of the trench with antiseptic agents. Among the latter most commonly employed are a saturated solution of the sulphate of iron and milk of lime freshly prepared according to the formulæ indicated in the prophylactic instructions in use for contagious diseases." After further instructions regarding the disposal of infected material, particular directions are given to ensure the safety of workmen engaged in disinterring and removing bodies from cemeteries—these, probably, being more frequently encountered in Paris than here. Besides the use of special antiseptics, ventilating apparatus, etc., "it is well each day in the morning to serve all persons engaged permanently upon the work an allowance of coffee and rum, as customary in Paris in the municipal service of disinfection. During the day the workmen should use exclusively as a beverage drinking water to which has been added a small proportion of coffee and a few drops of rum; it is not necessary to conceal the fact that this hygienic prescription will always be found difficult of application." (The author does not state whether or not the difficulty lies in securing the prescribed proportions of ingredients.) Indeed, the merits of rum appear to be well recognized in the municipal pharmacopœia, for it is further recommended that, to persons exhibiting symptoms of gastric trouble, or those afflicted with colic or diarrhœa, a small glass of rum, with essence of mint, laudanum and water be immediately administered.

Nor is the workman employed on maintenance neglected. Instead of groping his way down a contracted manhole containing a few straggling pieces of iron called steps, he enters an ample manhole on the sidewalk, the side furnished with steps which are vertical, instead of having an inconvenient "negative batter." A few steps bring him to a gallery which leads by a gentle slope to the sewer. The latter has a footway provided on one or both sides of the channel, and, where a gradient of over 3% obtains, not only are there steps to prevent slipping, but a handrail at the side and a gate (barre-de-surete) or chain at the upper end are provided to prevent accident by a misstep. In the meantime a simple contrivance holds the manhole cover propped up, if desired. There are, moreover, other manholes built directly over the sewer and without steps, solely for the purpose of dumping snow into the sewer in winter. This, of course, saves considerable expense in haulage. Flushing tanks, or reservoirs, have been largely introduced of late years. From 1881 to 1894, 2 274 of them were installed. They are frequently built in two compartments, one containing an automatic syphon and the other a valve for hand-flushing.

In measuring up the work, distances are always computed on the slope and, wherever possible, measured inside the sewer itself, instead of on the surface. The price paid per meter assumes a fill above the extrados of the arch of one-half a meter and a proper allowance or deduction per cm. excess or deficit, as the case may be, is made. A similar rule holds good where the work is laid on a foundation of masonry, the unit price assuming a uniform thickness of the latter of one-half of a meter.

From the above random notes, it will be seen that the methods of sewer design and construction are reduced in Paris to a very precise system—cut and dried, it would seem, to meet all ordinary contingencies. Formulæ, elements of design, wages, and, in fact, all possible details are, so far as practicable, permanently established; and in this way considerable subsequent litigation is no doubt avoided. And while there is much that would not bear transplanting to this country—as, for instance, the excessive number of fixed regulations concerning trivial matters whch might safely be left to an intelligent resident engineer—yet, there remains much for us to profit by in the observation of methods which have been thought out and applied with so much care abroad. The chapter containing an account of shield tunneling is especially well written, and particularly interesting as a process employed with such marked success under adverse circumstances on the Clichy Collector and from its recent adoption for the 39th St. intercepting sewer in Chicago. The book is generally clear and concise in style and contains many illustrations; moreover being printed in good open type on good paper, it makes an attractive volume. Two errors may be noted: On page 55 line 15 from top, in place of C insert D; and in Fig. 199, the surface of the subterranean sheet of water should be convexed upwards near the wells as midway between them.

ENGINEERING NEWS AND AMERICAN RAILWAY JOURNAL.

A WATER FILTRATION ORDINANCE for Philadelphia will probably be submitted soon to the Council's Water Committee by the Director of Public Works, Mr. Thos. M. Thompson. Meanwhile, Mr. Thompson will be relieved from consideration of the numerous bills looking to the filtration of the city water supply by private companies which have been referred to him during the past few weeks. This action is the result of a conference between the committee and the director, during which the latter plainly stated that he was tired of making reports which received little or no attention from the councils. He also urged the necessity of a thorough expert study of the filtration question, for which an appropriation would be necessary, in order to pay for outside advice and the other expenses of the investigation. An event which may have an important bearing upon the water question at Philadelphia is the ignoring by the Grand Jury of the bills of indictment for bribery in the Schuylkill Valley Water Co. matter. It may be remembered that an ordinance providing for a filtration contract with this company was being rushed through the councils last summer, when assertions on the floor that money had been paid for votes caused the indefinite postponement of the ordinance. The matter went into the courts, and the press and public seemed convinced that the charges were true. Greatly to the surprise of the citizens, the bills of indictment found by the judges have been ignored by the Grand Jury, so the cases must be dropped. It is said that the Schuylkill Valley Water Co. will bring in a new proposition early next year. This seems probable enough, for in the face of all the excitement and apparent defeat attendant upon the alleged exposures last summer, the company, it is said, moved into large and commodious new offices. Possibly the withdrawal of other private schemes from the consideration of the director of public works is intended to clear the way for the Schuylkill Valley Water Co. This company is said to be composed largely of Providence and New York capitalists, and to have organized two subsidiary companies; one a land and storage company, probably for the acquisition of real estate, and the other, known as the Providence Construction Co. Mr. Nelson G. Green, 309 Broadway, New York city, is special agent for the Schuylkill Valley Water Co.

◆

EXPERIMENTS ON THE USE OF OZONE for water purification are described at some length in London "Engineering" for Nov. 11 and 18. A briefer and more judicial account of the same experiments is given in the report of the Maine State Board of Health for 1896 and 1897, under "Notes on Disinfectants and Disinfection." The experiments have been made in Germany and Holland during the last six or seven years. Ozone is produced from air by means of high tension electric currents, ranging from 50,000 to 100,000 volts. Thus far the results obtained seem to be of no practical importance, so far as public water supplies are concerned. If the water to be treated with ozone is high in organic matter it is filtered first, at a rate, in some of the experiments, of about 4,000,000 gallons an acre. The ozone seems to be used principally to render the water absolutely sterile, which it apparently does. The expense of the process is not stated.

◆

THE EXTENSION OF STREET RAILWAY FRANchises in Chicago for a period of 50 years, referred to in our last issue, continued to agitate the people of that city through another week. On Dec. 19, the council voted to withdraw the ordinance, 40 to 23. A motion to refer the ordinance to a committee friendly to Mayor Harrison, and against the extension, was carried by a bare majority of one, the vote being 32 to 31. Five members of the council were absent when these votes were taken. The opponents to the extension demand that no ordinance be passed until the Allen law is repealed. This law was passed by the last legislature, under very suspicious circumstances, and gives authority for the proposed extensions.

◆

A COMBINATION OF STREET LIGHTING COMpanies, East of the Mississippi River, is announced from Philadelphia as going into effect on Jan. 1. An alleged infringement of gaslight patents by rivals of the Pennsylvania Globe Gas Light Co. is said to be the cause of the new consolidation. The deal provides for a capitalization of $12,000,000, and the companies involved are the following: Pennsylvania Globe Gas Light Co., Welsbach Street Lighting Co. of Chicago, New York and New Jersey Gas Light Co., of New York; the Chicago Globe Gas Light Co., the Canton Globe Gas Light Co., of Canton, O.; the Kitson Incandescent Gas Light Co., and two other companies not named. The deal carries with it four large factories, and 60,000 lights in different cities, soon to be increased by 50,000 lights contracted for by the Kitson Co. The Welsbach Co. is operating its system in 50 different towns. Except the Kitson, all these companies are controlled by the Pennsylvania Globe Gas Light Co., of which the stock is owned and controlled by the United Gas Improvement Co., of Philadelphia, or the Widener-Elkins-Dolan syndicate. The Kitson Co., for its $3,000,000 stock, gets $3,000,000 common stock of the new company, out of the $6,000,000 common stock authorized. Of the $6,000,000 preferred stock, $5,000,000 goes to the United Gas Improvement Co., along with the other half of the common stock; $400,000 preferred will cover cash in the treasuries of the two companies, and the remaining $600,000 preferred will be left in the treasury.

◆

ANOTHER CABLE-ROAD WILL BE TRANSFORMED to a conduit electric system. The Columbia Railway of Washington, D. C., notwithstanding the fact that it has a modern cable plant in perfect running order, will follow the example of the Capital Traction Co., of that city, and adopt the conduit electric system.

◆

COMPRESSED AIR now seems to absorb the attention of Mr. Joseph Leiter, who came into prominence last fall as a wheat manipulator, and it is reported that he has secured the controlling interest in the International Air Power Co., of New York, capitalized at $7,000,000 with the intension of extensively introducing it as a motive power for street railways, motor vehicles, etc.

◆

A $5,000,000 CONTRACT FOR STEAM AND ELECTRICAL machinery has been awarded to the Westinghouse Electric & Machine Co., of Pittsburg, Pa., by the Third Avenue R. R. Co., New York city. The plans of the railway company, in so far as they have been announced, include the erection of an immense power-house with a capacity of about 64,000 HP. on the company's property at 216th St., New York city. The conduit electric system will be installed on all of its lines. It is also understood that the company contemplates the sale of surplus power after the plan proposed by the Metropolitan Traction Co.

◆

THE NEW YORK RAPID TRANSIT COMMISSION, at its meeting on Dec. 15, decided to apply to the legislature to be relieved of the impediment of the municipal debt limit, and to be empowered to carry out its enterprise, either by the aid of private capital, or by issuing bonds upon the county of New York alone. The bill is being prepared for presentation.

◆

THE ANNOUNCEMENT that $40,000,000 is to be expended for public works in Greater New York, and that improvements are to be energetically pushed next year, comes as a surprise to those who lately heard so much of the debt limit being exceeded, etc. About $10,000,000 of this sum has already been authorized, and the power to raise the remaining $30,000,000 is to be provided for by an increase of $400,000,000 in the assessed valuation of property in the city.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred Dec. 15, on the Florida Central & Peninsular R. R., near Madison, Fla., as the result of a passenger train running into some cattle that were on the track. Six persons were killed.

A SERIOUS ACCIDENT occurred, Dec. 13, on the New York Central & Hudson River R. R., near Grimesville, N. Y., in which 8 men were killed and several injured. A gang of from 60 to 70 men were shoveling snow from the tracks and moved out of the way of a west-bound freight, when their attention was attracted by an east-bound passenger train. In getting out of the way of this second train several of them walked in front of the Atlantic Express, which had run down upon them unheard.

◆

THE FAILURE OF THE IRELAND BUILDING, in New York city, which took place on Aug. 8, 1895, and was discussed at length in our issues of Aug. 15, 22, and 29, 1895, is recalled to mind by a verdict for $10,000 damages against Mr. John B. Ireland, the owner of the building, by the widow of John Burke, one of about 15 men who were killed by the accident. A year ago a similar verdict was obtained in the same case, but it was set aside on account of defective proof. In that suit the jury exonerated the contractors, holding that the construction was under the personal supervision of the architect, the direct agent of Mr. Ireland. The Coroner's jury, which made a long investigation after the accident, held responsible the architect, his assistant, the contractor, his superintendent, the mason foreman, and an ex-inspector of the Department of Buildings, and the Grand Jury afterwards found indictments for manslaughter against all of these men, but we believe their cases were never brought to trial. Other damage suits against Mr. Ireland are likely to follow the verdict now given.

◆

A SAFETY GATE FOR DRAWBRIDGES, which is now in use at the Randolph St. bridge over the Chicago River, in Chicago, is similar in design to the gates extensively used at railway grade crossings, having vertically moving arms which extend across the roadway and sidewalk when the bridge is open. The apparatus and operation are very simple. Across the bridge run two transverse shafts, carrying four sprocket wheels, while four other sprocket wheels are mounted on vertical spindles at the corners of the bridge. Short lengths of sprocket chains pass round the wheels and are connected by light wire ropes. On the four spindles are four spur wheels, which have teeth 1¼ ins. long, in order to allow for the contraction and expansion of the bridge. These wheels engage with sprocket wheels on the abutments. Chains from these operate wheels under the gate posts, which in turn operate the gate arms by vertical chains enclosed in the cast-iron boxes or posts of the gate. The shafts on the bridge are operated by sprocket gearing by means of crank handles, the chains being enclosed in a small box or housing. When the bridge is to be opened, electric gongs on the approaches are rung by means of a push button on the housing of the operating gear. The bridge tender then operates one crank, thereby closing the diagonally opposite gates against the traffic, while leaving the other gates open to permit teams and persons already on the bridge to pass off. When the bridge is clear he operates the other crank and closes these latter gates. The bridge is then swung open in the usual way, leaving the gates locked. Each gate arm is made of two bars, which are brought together at the outer ends and spread apart so as to embrace the gate posts, the bars being connected by bracing. The gate is the invention of Mr. H. A. Paquette, of Chicago, and is being introduced by the Chicago Bridge Gate Co., 7114 Cottage Grove Ave., Chicago, Ill.

◆

A FIRE DESTROYED the frame building used by Mr. Allen Hazen, Assoc. M. Am. Soc. C. E., as a branch office during the construction of the filtration plant at Albany, N. Y., and located at 57 Lumber District, of that city. Many valuable records, photographs and plans, relating to the work were burned. Mr. W. B. Fuller, M. Am. Soc. C. E., Resident Engineer, had a very extensive library of engineering literature and private memoranda and several valuable surveying and calculating instruments which were all destroyed. Mr. John H. Gregory, First Assistant, also lost a large number of engineering books. There was no insurance. The unfortunate experience of these engineers would serve as a warning to engineers generally as to the wisdom of keeping books, drawing instruments, etc., insured, even when they are housed in temporary quarters on construction works.

◆

THE PARIS EXPOSITION OF 1900 is the title of a circular letter recently issued by Mr. Francis E. Drake, Director of Machinery and Electricity of the United States Commission, in which the location of the buildings is briefly given and the general conditions of installation and exploitation of steam boilers, general conditions of installation of the engine dynamo group and the conditions for the construction and operation of a number of inclined electric elevators are given in detail.

◆

THE PARIS EXPOSITION AUTHORITIES have awarded to the United States a total of 250,000 sq. ft. of space; but the demands from this country already call for 700,000 sq. ft., says U. S. Commisisoner Benjamin W. Woodward.

THE RECENT PARIS MOTOR-CAB COMPETITIONS.

In February, 1897, the Automobile Club of France decided to hold in Paris an international competitive trial of motor vehicles adapted to regular service as cabs in the streets of Paris. As a basis of comparison with the present cab service, it was decided, upon investigation, that the average daily run of a cab in Paris was about 40 miles; of which 28 miles were devoted to useful work, while the remaining 12 miles were consumed in passing between the stables and cab stands and in driving about the streets in search of passengers. The time thus covered was 16 hours per day.

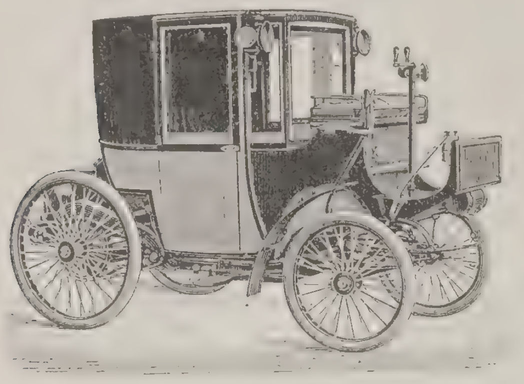

Fig. 1.—Peugeot Coupe; petroleum motor.

Based upon this estimate, the conditions of the competition required the mechanically propelled cabs to make a run of 40 miles in 16 hours over routes specified, with but two halts; one of half an hour and one of one hour for breakfast. This run was to be made for 12 consecutive days over 12 different routes, selected with reference to gradients. Within the City of Paris the speed was not to exceed 20 kilometers, or 12.4 miles per hour; the speed on grades was to be recorded mechanically; and each vehicle was required to make the 12 trips with the complement of passengers and baggage called for in its design, or to carry corresponding weights of 154 lbs. for a passenger and 66 lbs. for baggage. The detailed official report upon this trial is contained in "Le Genie Civil" for Sept. 3, 10 and 17, with illustrations of the motor-cabs used. A brief description of the vehicles and some of the conclusions arrived at follows:

In all 26 motor vehicles entered the race of last June, of which 14 were equipped with electric motors and 12 were operated by petroleum distillate engines. To feed the former a temporary but fully equipped electric generating plant was installed near the place of storage for the vehicles. As a basis for comparison of cost, the daily expense of running an ordinary Paris cab pulled by a horse was fixed at 19.26 francs, or $3.85. This sum included expenses of administration, rent of stables, repairs, horse-feed and attention, pay of driver, taxes and material, and it included the average use of 3½ horses per cab employed.

The first class of vehicles entered covered those with a single motor, where the power is transmitted to motor wheels through an intermediary; with gearing permitting a mechanical variation in speed. Under this head came the Peugeot coupe as a type (Fig. 1), propelled by a gas-engine and intended to carry three passengers, without baggage, or a useful load of 462 lbs. This vehicle was made up of a closed body, with two seats capable of carrying four passengers, and it did frequently carry this number during the trial. The driver or operator has his seat in front, and controls the apparatus for directing and changing speed and operates a brake-pedal. Attached to this front part is the naptha reservoir. The motor is placed in the rear of the carriage-body. The naptha reservoir, holding 35 litres, is in the driver's seat, and the water reservoir, holding 38 litres, is under the vehicle. The total weight is 2,838 lbs., with 1,509 lbs. on the front wheels and 1,329 lbs. on the back wheels. The out-to-out width of the vehicle was 5.25 ft., and the total length was 9.18 ft.

The motor used, with petroleum distillates, was built on the Peugeot system, the charge being exploded by incandescent tubes. It developed 6 HP. and weighed 231 lbs., with its fly-wheel and bedplate. The two cylinders are horizontal; 96 mm. diameter; 32 mm. stroke, and the normal revolutions were 680 per minute. These cylinders are cooled by the circulation of water, pumped from the water-tank around the cylinders and back to the tank. The motor-shaft is horizontal and parallel to the axle-tree, and it is connected with the shaft carrying the speed-differential by a friction-gear, which permits four changes of speed—3.7, 6.2, 9.3 and 12.4 miles per hour, and a backward speed of 9.3 miles. For braking purposes there is a ribbon-brake, lined with camel-skin, and working upon the box of the differential by means of the pedal.

The full detail of the test of this Peugeot motor is too long for insertion here, but some of the more important results are as follows: The average speed made was 14 miles per hour, with 3.7 miles per hour on an 8.2% grade. The jury figured that the daily cost of running this vehicle was $5.55; of which sum $2.17 was for oil, etc. consumed, and $3.28 was for other expenses.

Under the head of electrical motors the Jenatzy coupe (Fig. 2) is taken as a type. This cab was intended to carry two passengers, or a useful load of 308 lbs. It was made up of the ordinary cab-body with a bracket-seat, though this third seat was not used for a passenger during the trial. The driver sat in front and there handled a directing-bar, speed-variant and brake combined, and under foot was a pedal operating a friction-brake. The total weight was 3,964 lbs.; with 1,854 lbs. on the front wheels. The wheels were made of wood with metal hub, fitted with Michelin pneumatic tires. The extreme width of the vehicle was 5.9 ft., and the extreme length 9.2 ft.

The motor, speed-gearing and differential are enclosed in the body of the vehicle. The motor, excited in series, has a normal power of 4 to 5 HP.; but it may easily develop, according to the claim of the builder, 10 to 12 effective HP. Two normal speeds are arranged for—3.7 and 7.4 miles per hour; for the first speed the two batteries are connected in parallel, and for the second speed, in series. Special gearing is provided for passing from 3.7 to 5.6 miles speed, and from 7.4 to 12.4 miles speed, and intermediate speeds can be obtained by introducing momentary resistance coils. The accumulators are of the Fulmen type, B 21, forming two batteries of 22 elements each; each enclosed in a box; one under the driver's seat and one behind the carriage. These two boxes are easily opened for taking out and replacing the batteries.

The general speed results were as follows: On the level the batteries in parallel gave an average speed of 5.27 miles per hour; in series they gave a speed of 10.4 instead of the promised 11.2 miles per hour. On a grade of 8.2% the batteries in series gave a speed of 4.9 miles per hour. The jury figured that the daily cost of operating the Jenatzy coupe was $4.05, of which 80 cts. was for the repairs to the accumulators and 34.4 cts. was for the electricity; the rest went for general expenses.

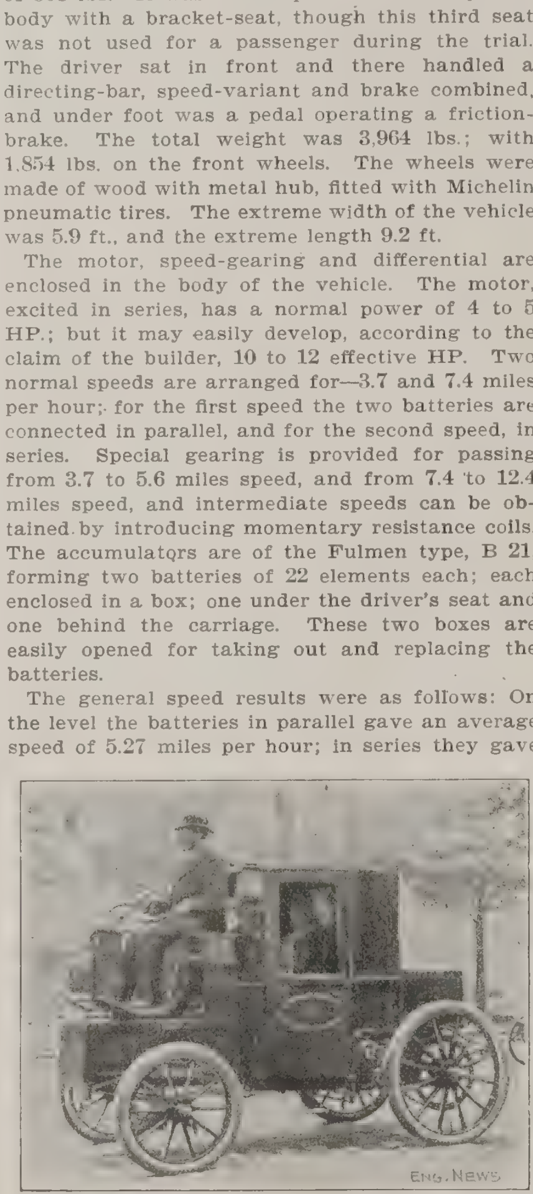

Fig. 2.—Jenatzy Coupe; accumulator system.

The second class in the test included vehicles with a single motor, where power is transmitted by motor-wheels by means of invariable gearing, with a differential and chains; and where the variation in speed is secured by a corresponding variation in the speed of the motor. Under this head the electrically propelled Jeantaud cab (Fig. 3) is taken as a type. This cab is intended to carry two passengers, or a useful load of 308 lbs. It can be made to be sold for $2,800. It is a four-wheeled cab, with the forward wheels carrying a box enclosing the accumulators; the driver is behind, and there controls all movements. The motor and differential gear are under the cab. The total weight of the cab is 3,102 lbs., with 1,419 lbs. over the front wheels. The wheels are wood with metallic hub and Michelin pneumatic tire; the extreme width of the vehicle is 5.08 ft., and the extreme length is 9.7 ft.

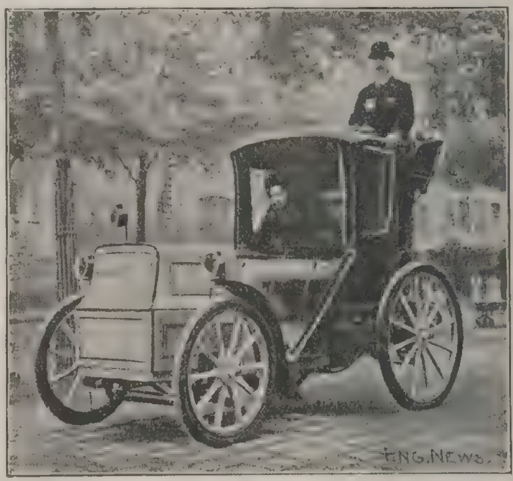

Fig. 3.—Jeantaud Cab; accumulator system.

The motor and shaft of the differential are placed in a closed box, with the ends of the differential shaft projecting and carrying pinions for the sprocket chains; this motor, with its transmission gear, weighs 330 lbs., and has a normal power of 3½ to 4 HP. Different variations of excitation and the coupling of the batteries permit speeds ranging as follows: 4.34, 7.44, 9.3 and 11.2 miles per hour. Intermediate speeds are obtained by momentary resistances introduced through the pedal of the electric brake. The accumulators are of the Fulmen type, B 15; they contain 44 elements and weigh in all 880 lbs. Transmission is by a sprocket-wheel and chain connecting the ends of the differential-shaft and the corresponding motor-wheel.

The mean maximum speed made in the trial was 10.5 miles per hour; the daily cost of running this cab was fixed by the jury at $3.96.

A Jeantaud landaulet, Fig. 4, was also submitted to test, which carried two passengers and cost $2,800. It weighed 3,652 lbs. Fulmen accumulators, B 17, weighing in all 1,005 lbs., were used, and the general plan of transmission, etc., was similar to the cab first described. The daily cost of operation was fixed at $4.04.

The third class of vehicles included those with two motors, one for each motor-wheel; geared directly to it with no provision for change of speed, except by changing the speed of the motor.

To this type belonged the Krieger carriage, Fig. 5, arranged so that the body of the carriage could be changed without interfering with the motor mechanism. The coupe and victoria types would carry three or four passengers without baggage; the useful load is 462 lbs., though in the trial they often carried 616 lbs. Either of these carriages could be sold for $2,400 each.

In these carriages the accumulators are stored in two boxes; one under the seat of the driver, and one behind the body of the carriage. There are two motors, one for each front wheel, and these are both motor and directing wheels, the motors being placed directly over the vertical pivots. The coupe weighs 3,608 lbs.; the victoria 3,498 lbs., and the coupe, with a compartment for baggage, weighs 3,894 lbs.

The two electric motors are of the Krieger type, made by Postel-Vinay. Each has a nominal power of 3 HP., and weighs about 143 lbs. Varying speeds of from 3 to 12 miles per hour are obtained by means of a series-parallel controller. In the trial, speeds of 5.5, 12.3 and 15.9 miles per hour were made on the level with batteries in series; on a grade of 8.2% the speed was 3.7 miles per hour in series. The total daily expenses of running the three types of Krieger carriages were fixed by the jury at $4.05 to $4.06.

In its general conclusions the jury says that one of the most striking features of this trial was the preponderating influence of the cost of repairs to the accumulators and the pneumatic tires, upon the daily expenses of running electric motor-vehicles. The small quantity of electrical energy consumed on this total course of 347 miles, on some of the most crowded streets of Paris, and the small cost of supplying this energy, was one of the suprises to the jury. In the daily expenses for the Jenatzy, Krieger and Jeantaud motor-carriages the specific energy supplied only cost, on the average, 35.4 cts., 34.8 cts. and 20 cts. respectively. This extremely low cost, says the jury, seems to render it almost practically useless to seek for better methods of utilizing the electric motor in propelling vehicles. But while the consumption of energy has so slight an influence upon the daily cost of operation, the enormous general expenses which swell this cost must not be lost sight of. The electric motor must be designed to reduce to a minimum the consumption of energy on streets with steep gradients, and so regulated and controlled that an inexpert driver can not communicate to the motor currents disastrous to the accumulators.

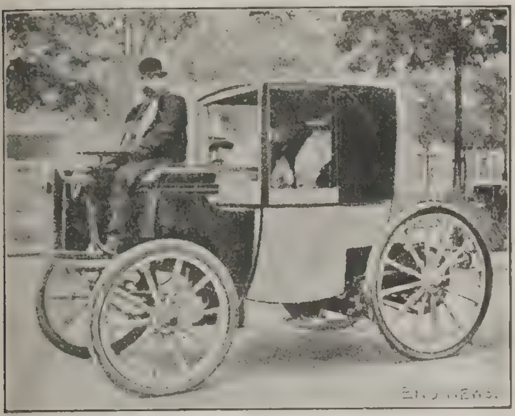

Fig. 4.—Jeantaud Landaulet; accumulator system.

As to speed, while this was generally satisfactory, the jury hopes that in another year makers will submit motor-cabs which will better meet actual cab practice in Paris, and with as small a consumption of energy as possible, meet the following speed conditions:

4 miles per hour in seeking passengers.

5 miles per hour mounting 5% grades.

7.5 miles per hour on grades from 2.5 to 5%.

9.3 miles per hour as an average in ordinary streets.

12.4 miles per hour in open and uncrowded streets.

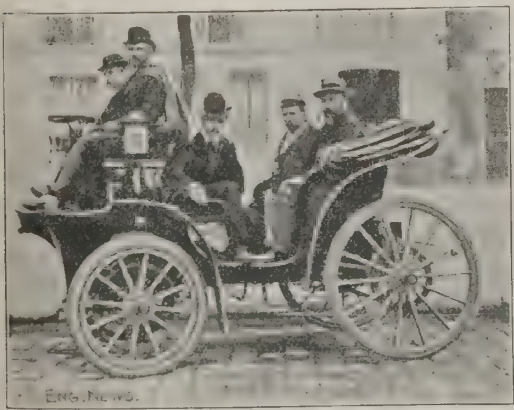

Fig. 5.—Krieger Victoria; accumulator system.

At the present time the police regulations of Paris only permit a maximum speed of 7.5 miles per hour in the city streets, and 12.4 miles per hour outside the city walls. The jury contends that the law should be changed so as to authorize a speed of 12.4 miles per hour within the city; if this were done the authorities could be assured that ordinary conditions would prevent a speed much exceeding 7.5 miles per hour in crowded streets. During the motor trial of last June, covering nine days in time and 3,720 miles in distance, the average speed maintained was about 9.3 miles per hour.

The jury says that one of the most difficult things to contend with, in attempting any great speed with motor-carriages on the streets of Paris, is the tendency of the wheels to slip on muddy streets, causing the carriage sometimes to swing clear around. This trouble is aggravated by having the directing wheels in front; and it thinks that some means should be adapted for braking the hind-wheels in case of breakage or damage to the brakes on the front wheels.

THE RELATIVE IMPORTANCE OF FLIES AND WATER SUPPLY IN SPREADING DISEASE.*

The diseases that may be borne in water under some circumstances and by flies under others are typhoid fever, yellow fever, certain forms of dysentery, Asiatic cholera, and perhaps malarial fever, and malarial poisoning in general.

It will be observed that there are two classes of these diseases, the intestinal and the malarial. In the former the infection is a bacillus of some sort, whose presence in any locality can always be traced to some preceding contamination by excretions from a diseased bowel. In the latter the source of infection is a plasmodium, as it is termed, which lives primarily in marshy soil, or stagnant water, and whose presence in that location is independent of contamination from human sources. These distinctions are to be kept in mind constantly in attempting to trace out the manner in which these diseases spread, and in adopting measures for their prevention.

All are most emphatically camp diseases, and hence the propriety of their discussion at a meeting devoted to the subject of "Camp Hygiene." There is the greater need of such discussion because the relative importance of flies and water supply in spreading disease has been greatly misunderstood, especially in the very case of camps where the danger is greatest.

Contrary to ideas that have existed heretofore, in camps and under similar conditions elsewhere, intestinal diseases are spread almost exclusively by flies, and malarial diseases by water. The exceptions to this, which are relatively unimportant, will be noted in the course of the discussion.

In the Cuban campaign last summer it was sought to prevent the spread of diseases of the intestinal class by the use of water from the purest sources, or purified by boiling. It was a failure. Not until late in the summer was the agency of flies taken into the account in any practical way. Even now reports from Honolulu and Manila state that typhoid is still epidemic among the soldiers in those localities, showing that adequate measures of prevention have not yet been perfected. Likewise during the recent British campaign in Fashoda, which was most carefully planned, and which took place in a climate that is exceptionally dry and hygienic, there was no abatement of typhoid fever, it continuing to be the chief scourge of the army.

Nevertheless, diseases of the typhoid type can be prevented with almost absolute certainty, and malarial diseases greatly abated, in both instances by very simple measures. It is only necessary that those most concerned should think it worth while to understand the matter and act accordingly.

It is not possible to enter very much into detail in a brief summary of results such as the present. Suffice it to say that in the performance of his duties as Health Officer and practicing physician, the writer has been able to put an end to epidemics of typhoid fever and dysentery of the exact type that prevail in the army in such manner as to warrant the belief that the problem of their prevention has been solved completely.

For example, the outbreak of malignant dysentery mentioned in my paper at the recent meeting of the American Public Health Association was encountered when at its height, there having been forty cases and ten deaths and the disease spreading rapidly from house to house in a single neighborhood. As soon as measures were adopted such as would make conveyance of the infection by flies impossible, there was not another new case, although there had been fresh ones every day for some time previously. In like manner the past summer a lively epidemic of typhoid fever was ended in a day by measures directed against conveyance by flies. So, too, on the malarial side of the question there has been prevention, without the aid of quinine, by measures directed against conveyance by water.

It is true that under certain circumstances the poison of intestinal diseases may find its way into water and be thus conveyed, and that the poison of malaria may be taken up and carried by mosquitoes or flies, as the case may be. Hence, it is necessary to discriminate carefully in reference to the peculiarities attending these different methods of conveyance of infection.

When flies are responsible there are little neighborhood epidemics extending in short leaps from house to house, without reference to water supply or anything else in common. But when water is at fault the disease follows its use wherever it may go, the only limitation being the resisting power of the individual using it, and such househould measures of boiling and the like, as tend to destroy disease germs. Epidemics spread by flies tend to follow the direction of prevailing warm winds, as though the fly, wandering out doors after contact with some source of infection, had drifted with the wind; but nothing of the sort is perceptible in the case of water-borne disease. In villages and camps where shallow open closets are in use, giving access of flies to the chief sources of infection, they are the chief medium of its conveyance. In cities where underground sewers carry such material beyond the ordinary reach of flies, whose migrations are not extensive, such diseases can only become very prevalent through infection of the source of public water supply. Hence in villages and camps they are usually fly-borne and in cities water-borne. When a source of public water supply has been infected in this manner, cases of the disease will occur more or less throughout the year, provided that the germ remains active at all temperatures. When the conveyance is by flies the prevalence of the disease will be confined to a particular season exclusively. Thus in cities typhoid fever prevails at all seasons, in villages it is an autumnal disease. When the weather is dry and sultry flies have their best opportunity to carry the disease, or, in other words, under the very conditions best adapted to prevent its spread if water-borne.

With this understanding of some of the more prominent general relations of the subject, it becomes possible to enter into the study of details that are of the utmost practical importance. For example, in investigating a series of epidemics confined to a single neighborhood recurring year after year, the writer, following the lines that have been indicated, was able to secure very positive evidence, both clinical and microscopical, that burying typhoid material in the ground is no protection against flies. Such a procedure simply establishes a culture bed in which the bacilli, like plants, grow toward the surface, attracted by the warmth and other effects of the sun's rays in that location. If any prevention whatever is secured by such burial of typhoid material without disinfection, it is very transient, especially when the weather is sultry. The application of this to the care of the sinks in the army is evident. Indeed, it is the key to the situation, so far as army conditions are concerned, the danger being greatly intensified by the utter heedlessness of many of the men. Discipline as well as accurate knowledge is required, in order to make preventive measures a success in this case. Indeed, unless carefully looked after, there will be neither burial nor disinfection of such material, far too often.

Furthermore the burial of typhoid material not only fails to prevent the immediate spread of the disease, it on the contrary actually perpetuates it in the locality from year to year. This was clearly shown in the series of epidemics referred to in the preceding paragraph, which came to an end at once when this mode of disposal of material was abandoned, and proper disinfectants were used.

The subject of disinfection in general demands revision from the point of view of the present discussion. The material employed must be suitable. If of a volatile nature like carbolic acid it must be remembered that on evaporation it will leave nothing behind to protect against reinfection, and consequently must be used in large quantities and often, so that not a single particle of material containing living bacilli may escape to re-infect the entire mass. Sulphate of copper in solution, on the other hand, on evaporation, is left behind, diffused through the material, thus prolonging its effect, and even making it permanent, if a sufficient quantity has been employed. Earth containing sulphate of copper thus diffused becomes a good disinfectant, and may be used with confidence to cover typhoid or other infected material.

The time at which disinfection is to be performed is likewise of the utmost importance. If a case of intestinal disease is in progress, the material from the diseased bowel should not be exposed to access of flies without disinfection for a single moment. It is taking serious chances to allow even a single fly to crawl over such material, and then visit articles of food and drink. No matter how cleanly the premises, or what other precautions may be taken, if instant disinfection be neglected, the danger becomes impossible to compute. On the other hand, a very little care at the right time yields a result that is an absolute certainty and that even a child can understand.

Among large bodies of men there will always be some who are negligent, and even among those who are thoughtful, the very beginnings of an attack of sickness may pass unnoticed. Thus there is constant danger that bacilli from the diseased bowel will be planted in the sink and there find opportunity to grow and propagate. Consequently there can be no security unless all excretions are disinfected instantly, if possible. Just here the point that has been made in regard to sulphate of copper in solution as a disinfectant may prove to be the key to the situation. The writer has had large experience with its use for this purpose, and has been surprised many times at the way in which even so small a quantity as a pound or two diffused through several barrels of water checked putrefaction and all signs of bacterial growth in foul drains and the like. The fact that soil can be converted into a good disinfectant by its aid is likewise important. It is portable and its color is such that there is no liability of mistake, and it likewise has the advantage of showing visibly exactly how far it has penetrated. It would seem to be the ideal disinfectant for army use, if its efficiency is as great as the writer has been led to suppose. In the absence of water it can also be used dry with good effect, but a larger quantity is required.

---

*Abstract of a paper read by Dr. M. A. Veeder, of Lyons, N. Y., at a meeting of the Buffalo Sanitary Club, Dec. 14, 1898.

If, however, during the exigencies of a campaign no special means whatever of disinfection are at hand, it is nevertheless possible to do much. For instance, it is a good plan to follow the example of the Indians, who change the location of their camps often. Although burying infected material is at best a very uncertain precaution as against conveyance by flies, still it may lessen the chances somewhat for a period of some hours, more or less, according to the quantity or character of the earth employed. Hence it may be resorted to as a temporary expedient, in default of a better, when a camp is to be abandoned very soon, for example, or in the interim between the hours at which disinfectants are to be applied.

If so cumbersome an arrangement as the tank, fourteen feet long and two or three feet square, containing a strong solution of crude carbolic acid, to receive the excretions, as recommended by the commission appointed to investigate the spread of disease in the army, can be had, and its use insisted upon, there is no doubt but that a vast amount of sickness will be prevented. The idea of its use is certainly based upon a correct understanding of the dangers involved, and is something new in army sanitation. Perhaps inventive genius may evolve something even better, and more readily available under all of the exigencies of warfare, now that it is known precisely what it is necessary to accomplish.

Pretty much everything that has been said thus far has had reference to the prevention of conveyance by flies, this being the greatest danger in camps. Still there may be times when the use of water that is liable to contain the bacilli of intestinal diseases cannot be avoided. It may be necessary also to use water from soil in which the plasmodium of malaria is indigenous. In either case boiling is a precaution that has the merit of absolute certainty. If it is possible to make a fire and make a little coffee or tea to drink on the spot, or fill the canteens for subsequent use, it relieves the difficulty completely and at once.

With reference to this mode of escaping malarial disease by not touching water that has not been boiled, the writer has reason to believe that the security it affords is well-nigh absolute. It is possible that there may be some small conveyance by mosquitoes, which are known to harbor the malarial parasites. There is a likelihood also that flies that have come in contact with freshly upturned marshy soil may carry the infection to some extent. But the chances in both these regards are so small that they are nothing compared with drinking the soakage from swamps fairly reeking with the poison. The deepening of wells in marshy soil may be of some assistance, especially if they are of the artesian variety, not admitting water except at the very bottom of an iron pipe. This also avoids contamination with surface filth, and if such water could always be had there would be no need of other precautions. Under army conditions, however, it is better to cultivate the habit of boiling the water as a protection against diseases of the malarial type especially. There are many persons known to the writer who find it cheaper and pleasanter to do this than to dose themselves with quinine while undergoing slow processes of acclimatization, so-called, on any change of residence, for it is a peculiarity of malarial infection that immunity against it in one locality does not always protect in another. Hence there is the greatest need of preventive measures on the part of soldiers, who are liable to be constantly changing their location.

It is evident that much was expected in a sanitary way during the recent campaign against Spain, although it was organized in such haste. The American people do not appear to be willing to tolerate the idea that their boys at the front should be sick at all. At any rate, if there has been suffering and death, they want to know the reason why. It is a healthy symptom. But sanitation under the guns of the enemy is a hard matter, implying thorough knowledge and discipline. If anywhere this should be found, it is on the part of the American soldier who exhibited such magnificent initiative at Santiago. With the tremendous efflorescence of patriotic feeling taking the form of sanitary inquiry in the manner that it has, the Spanish-American war of 1898 may come to be known as the war that saved more lives than it destroyed many thousandfold.

BITUMINOUS ROCK PAVING IN SAN FRANCISCO, CALIFORNIA.

At the present time Market St., the chief thoroughfare of San Francisco, Cal., is being paved with the so-called bituminous rock. We are indebted to Mr. James M. Owens, B. S.,* of that city, for the following information concerning this material and its use in California.

Bituminous rock, as found in California, differs from that obtained from Seyssel and Val de Travers in one important particular; it is a bituminous sandstone while the others are bituminous limestones. Stratified deposits of this bituminous sandstone rock are found in a number of localities in California, and also in Kentucky and Utah, though California produces more than 80% of the total yearly output of this material. Probably the best known and most productive mines in California are in Santa Cruz Co.; and the most noted mine in this county is about eight or nine miles from the town of Santa Cruz, N. 76° W., and about 90 miles from San Francisco. It crowns the top of a hill, and is only three miles from the ocean. This mine was first opened in 1864-5, and the material was then distilled to extract the oil. The first shipment of this oil to San Francisco was destroyed by fire when in storage, the project was abandoned and the mine remained unworked until early in the 80's. Most of the work in developing the mine has been done since 1885.

Plant for the Reduction of Bituminous Rock by the Hot Air Process, for Street Paving in San Francisco.

This rock is a dark chocolate brown in color, almost black, almost odorless; and in the harder varieties the fracture is irregular, fine-grained and without cleavage planes. At low temperatures it breaks up into fragments like ordinary stone. The rock from the Santa Cruz mine is classified as hard, soft and medium rock; the hard rock, upon analysis, shows a very fine quartz, about as fine as beach sand. The soft rock contains pebbles sometimes ⅛-in. diameter. The Santa Cruz rock carries from 10 to 21% of bitumen and 0.8 to 0.3% of moisture. The specific gravity varies from 1.4 to 1.9. The deposits dip slightly towards the sea, and are from 10 to 30 ft. in thickness, and in most cases are underlaid by a moderately coarse-grained, clean, soft sandstone. The top rock is a very fine-grained, white, clayey sandstone. Numerous fossil remains of marine animals are found imbedded in the rock. The accompanying table contains the results of analyses made from samples of the Santa Cruz rock:

Analyses of Santa Cruz Bituminous Rock.
(Analysis by Thomas Price & Son, San Francisco, Cal., April 28, 1890.)

N. B.—Under the microscope the hard rock shows fine granular structure, and the presence of considerable bitumen. In portions of the soft rock large sized pebbles are quite visible.

Of the several patented processes now employed in San Francisco for reducing this material one of the oldest, and probably the most widely used, makes superheated steam the reducing agent. Disintegration by means of hot air, with petroleum as fuel, is the chief characteristic of the second process; the first method is intermittent and the second continuous. The accompanying cut shows a plant at work by the hot-air process. In the steam process the rock is broken into fragments of about egg-size; is wheeled up an incline and dumped into the kettle through an opening in the top. When filled the lid of the kettle is clamped down and the cooking process is commenced by the use of superheated steam. As the rock is melted it falls into a lower chamber and is removed when disintegration is complete. It is then ready to be taken to the work. Each of these kettles holds about ten tons; and with average rock about 40 minutes are required for complete reduction.

In the hot-air process, the kettle is filled automatically by an endless chain of buckets which deliver their contents into a hopper at the top and rear of the oblong kettle. From the hopper the broken rock finds its way into a revolving cylindrical crib, about 3 ft. diameter and the full length of the kettle; the openings in this crib are about ¼-in. apart, and through these the disintegrated material passes to a chamber below. This chamber has a double jacket of boiler-plate through which hot-air circulates, and this jacket extends up the sides so as to partly envelope the crib. In the bottom of the chamber, and running its full length are two longitudinal screw conveyors, about 12 ins. diameter. These deliver through openings in the end of the kettle. It requires a 7½-HP. engine to operate the mechanism attached to the kettle; and with a fair grade of rock this kettle can turn out enough material to lay about 9,000 sq. ft. of finished roadway, 2½ ins. thick, in one working day. With the so-called hard-rock, this amount is reduced as low as 5,000 sq. ft.

The method usually adapted in laying this pavement is as follows: Bituminous rock disintegrated and hot as it comes from the kettles, is spread over the concrete foundation by means of hot iron rakes. Heated hand-rollers, weighing about 20 lbs. per inch of tread, are then passed over it until a smooth surface is obtained; and while still warm the surface is dusted with infusorial earth which is a powerful absorbent, with the object of preventing adhesion between the wheels of the roller and the pavement. Finally, a steam-roller, weighing about 300 lbs. per inch of tread, is passed over the pavement, until the wheels of this roller cease to show any indentation. The pavement is then considered fit for traffic.

---

*643 Haight St., San Francisco.

Since bituminous rock pavement was introduced into San Francisco, about 13 years ago, over 72 miles of pavement have been laid and it is growing in popularity. During the fiscal year ending June 30, 1898, more bituminous rock pavement was laid than in any preceding year, or 74,533 lin. ft.; and this amount exceeds that of any other type of pavement laid in one year since 1893. Macadam is now used in outlying districts only, and cobble pavements are in limited use on steep gradients where smoother pavement would be out of question. The advantages claimed for bituminous pavement are: ease of traction; it is impervious; it is adapted to all kinds of traffic; produces neither dust nor mud, and is easily cleaned; is comparatively noiseless and has considerable elacticity; it is easily laid and repaired and is durable; and on account of its highly granular texture, due to the presence of a large excess of sand, it is not so slippery as asphalt. It is also comparatively cheap; for, in San Francisco, this class of pavement costs from 18 to 28 cts. per sq. ft., or $1.62 to $2.52 per sq. yd., according to difficulties encountered in laying it.

But notwithstanding its many good qualities, bituminous rock pavement has its faults. It is not adapted to grades steeper than 4%; in foggy or damp weather, a thin coating of mud is likely to form on the top of the pavement, if it has not been properly cleaned, and under these conditions the surface becomes slippery for smoothly shod horses. When the pavement has become thoroughly wet, however, this slipperiness is reduced to a minimum. Unless ordinances are enforced regulating the width of tires and the travel upon streets having car-tracks, it is not suitable for constant and heavy traffic, and will wear in ruts. In San Francisco a recently enacted ordinance forbids the driving of any vehicle over a street paved with bituminous rock, and upon which car-tracks are laid, in such a way, that two of the wheels run in the groove of the outer-rail while the other two are running on the pavement proper.

The specifications for the repaving of Market St., San Francisco, with bituminous rock generally provide as follows: The roadway is to be excavated to a depth of 11½ ins. below the finished surface and brought to a true arc with a rise of 1 in. in 3 ft. from the curb to the center of the roadway. After the roadway is properly graded it is thoroughly compacted by a 5-ton steam roller, and all soft places must be dug out and refilled with suitable material, well-puddled with water and re-rolled. On this road-bed will be laid a concrete foundation of 9 ins., made of 1 part Portland cement, 2 parts clean sand and 7 parts clean hard rock, the latter either blue or gray sandstone. Before laying the bituminous rock, the surface of the concrete must be allowed to become thoroughly dry and it must be then broomed and cleaned.

On this foundation the disintegrated bituminous rock is to be spread in equal parts of soft and pulverized hard rock thoroughly mixed. The mixture must contain 12 to 15% of natural bitumen; must be of even texture; free from quartz, sulphates, clay, gravel or other impurities. This mixture shall then be heated in a suitable closed kettle, adjacent to the work, to about 215° F., by a process whereby neither wet nor dry steam, nor flames of eny description, nor the direct heat from flames, shall be allowed to come into direct contact with the mixture. The heated rock is applied in a layer 2½ ins. thick, as before described.

A SECTIONAL DUMP CAR.

In most of the large dump cars now used for ballasting, filling, and other railway and construction work, provision is made for regulating the operation of dumping, so as to deposit the material in any desired quantity, at any particular point. This is usually effected by means of the doors through which the material is discharged, but in the Page car, which we illustrate this week, it is effected by mounting a series of dumping boxes on the car frame.

The Page car is made in two styles: The side-sill car has six boxes (three on each side) which discharge the load on opposite sides of the track; the center-sill car has three boxes (each the full width of the car), which can discharge their load on either side. In the side-sill car, the boxes are pivoted nearly over the sills, while in the center-sill car they are pivoted over the center sill. The builders consider that the center-sill type is in general preferable, since it enables the entire load to be dumped on either side of the car.

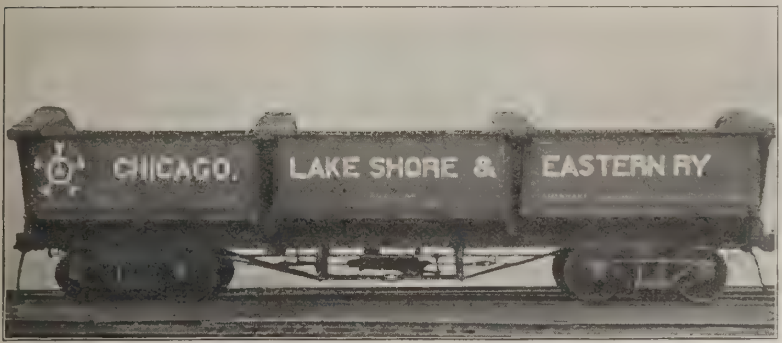

Fig. 1.—Page Sectional Dump Car in Running Position.

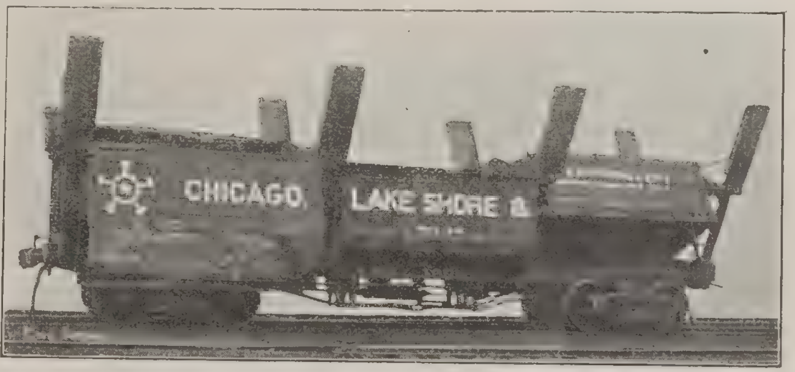

Fig. 2.—Page Car, With Two Boxes Dumped and the Third Ready for Dumping.

THE PAGE SECTIONAL DUMP CAR AS USED ON THE CHICAGO, LAKE SHORE & EASTERN RY.

The Sheffield Car Co., Three Rivers, Mich.

The accompanying cuts represent a car of this latter type. The underframe consists of five longitudinal sills, two end sills, and two intermediate cross sills, with transverse tie-rods, the whole frame being stiffened by four truss rods. On the end and cross sills are erected frames which support the dumping mechanism, latches, etc. The three dumping boxes are all the same size, and are pivoted on a steel T-bar over the center sill, the bar extending the full length of each box and being bolted to the bottom of the box. The boxes rest and rock upon flat iron straps on the upper face of the center sill. A malleable iron extension of the T-bar enters a cast socket which is secured to the end and cross sills, to hold the boxes in position over the sill. To avoid heavy framing in the ends of the boxes they are not built with a view to sustaining the pressure of the load unaided, but are reinforced by the vertical frames, which are provided with anti-friction rollers, engaging with bearing points on the boxes.

The sides of the boxes are closed by doors which hook on to lugs on the ends near their upper edges, and are secured at the bottom by straps entering keepers on the side sills of the boxes. Their action is automatic. As the boxes tip, projections on the doors first drop into seats on the caps of the frames, to prevent further downward movement. They are then released from the box and hang swinging. Latches pivoted to the vertical frames engage lugs at the four upper corners of the boxes. When returned to position the boxes are automatically locked.

Sheet steel shields, hinged to the outer ends of the vertical frames, cover the latches and the frames, and serve to prevent material from falling between the boxes and dropping on the ends of the latches. They also prevent the raising and releasing of the boxes. The hinges of these shields are provided with safety hooks, which engage the boxes, so that each box is thus secured with four latches. Buttons are placed on the middle frames, where the ends of the shields meet, and these may be turned so as to prevent the raising of the shields. A spring on the bottom shaft maintains a pressure so as to prevent the button from being turned by anything but a special wrench. This wrench is intended to be kept only at the unloading point, insuring against the boxes being dumped anywhere else, since none of the boxes can be dumped unless the shields are raised.

On construction work where many men are employed, the boxes may be tipped by a direct lift, and sometimes by means of cant hook levers. If, in loading the car, care is taken to trim the load, it is only necessary to raise the latches, whereupon the boxes dump automatically. Under favorable conditions one crew of men has unloaded and restored the boxes of a car for loading in one minute. Where a large number of men are not at hand, a dumping device may be employed, by which two men, standing on top of the vertical frames, one at each end of the box, can tip the boxes to either side of the car. The dumping device consists of a malleable iron casting, so constructed as to admit of attaching it to the box end at its highest point. The casting projects over a rack on the vertical frame, and is provided with pawls which drop into the rack. An opening in the casting admits of the insertion of a lever, which is used in moving the casting over the rack. The rack is used as a fulcrum of the lever, the pawls dropping into the indents of the rack and holding whatever is gained by each lift of the lever. With one of these devices at each end of the box it may be tilted to any angle desired and kept from tipping back.

The door opening of these boxes is large enough to allow a 3-ft. cube to pass out. When occasion demands, the doors can be removed and the car used as a flat car. The floors being horizontal the car is available for a great variety of freight service, whether it is desired to dump the load or not. It is claimed that the car can be used for hauling such materials as earth, sand, ore, coal, ballast, building stone, pig-iron, cinders, etc., which can be discharged by dumping or shoveling, or by means of a derrick. One of the special advantages claimed is that a sticky or frozen load will be discharged more readily from a tipping box than from a car having a stationary inclined floor.

A number of these cars are in use on the Chicago, Lake Shore & Eastern Ry. They are 36 ft. long, with a carrying capacity of 60,000 lbs. and a bulk capacity of 42 cu. yds., and are mounted on ordinary diamond frame freight car trucks. The floor, which is covered with 3-16-in. steel, is 4 ft. 8 ins. above the rails, and the top of the side is 8 ft. 2 ins. above the rails. The cars are fitted with air brakes and automatic couplers.

Some of them were built by the Pullman Car Co., of Chicago, and others by the United States Car Co., of Hegewisch, Ill. Mr. W. G. Brimson, President of the railway company, informs us that the cars were built for the purpose of ballasting and filling trestles. Since that work has been finished they have been used successfully for about two years in the coal and ore traffic, with practically no cost for maintenance. These cars are of the center-sill type.

Fig. 1 shows one of the cars in its normal running position, and Fig. 2 shows the same car with one box dumped to the right, another dumped to the left and the third ready for dumping.

These cars were invented and patented by Mr. C. D. Page, of Greeley, Colo., who is now in Seattle, Wash., building some cars of this type for the White Pass & Yukon Ry., of Alaska. The new cars are 36 ins. gage, 3 ft. 6 ins. long. Each car carries two boxes, the inside length of which is 13 ft. 3½ ins. They are to be used on construction for hauling ballast, railway ties and other building material. Later on they will be put into coal service.

For information respecting these cars we are indebted to the Sheffield Car Co., Three Rivers, Mich., which is interested with Mr. Page in the patents.

FIREPROOF FLOOR SYSTEMS USED IN LONDON.[*]

By Frederic R. Farrow.[†]

In the earliest forms of fireproof floors used in London, the aim of the inventors seems to have been simply to provide a floor of non-combustible material, and for a very long time the importance of preventing damage to the incombustible components of fire-resisting floors was wholly neglected; but, at the present day, it is almost needless to point out that it is quite as important that the construction of a fireproof floor should be such as to obviate the possibility, or at least the probability, of damage occurring to the building by failure of the floor in several other directions besides that of combustibility. A fireproof floor to be of any reliable value must not permit of any part of its construction being melted, distorted, or broken by the action of the heat of the fire, or by the water used in quenching the fire, nor must there be any possibility of damage by expansion or contraction of the various constituents of the construction under the greatest extremes of heat and cold to which it may be exposed.

The importance of avoiding damage by expansion and contraction militates against the employment of some otherwise admirable materials. It also renders it imperative that all metal work shall be preserved, not only from the direct action of fire, but also from the convection of any considerable amount of heat by such protective sheathing as may be incorporated in the construction of the floor.

Perhaps the earliest attempt at the construction of fireproof floors was the employment of a series of iron girders supporting brick arches which rested upon the upper surface of the flanges. In some of the very earliest examples, the girders were of cast-iron, but the system was continued subsequently with rolled iron joists. Those who used this form of floor evidently felt that there might be some possibility of trouble arising from the thrust of the arches, and therefore in some cases wrought-iron tie-rods were inserted below the level of the brick arches. The result could hardly be otherwise than disastrous; the girders and tie-rods were exposed to the full action of both fire and water, and the failure of one girder meant, of course, that of the arches supported by it, which necessarily would be speedily followed by the collapse of the whole floor from the thrust of the remaining arches. Such an unsatisfactory method of construction may now, we hope, be relegated to the limbo of forgotten ineffectiveness. The use of unprotected iron girders for supporting incombustible construction of various kinds remained, however, the common practice for a very long time; and although suggestions were made for adequate protection of the iron many years ago, it is but quite recently that this has been generally regarded as a sine quâ non in the design of a satisfactory fireproof floor.

The varied forms of fireproof floors which have been devised may be classified into those which do not attempt complete protection of the ironwork, those which do attempt complete protection of the ironwork, and those in which endeavors are made to dispense with ironwork, or, at least, iron joists altogether. In each of these classes we have a subdivision into those forms of construction which require temporary centering, and those which provide their own centering, or have a permanent centering.

There are but few examples now in use of fireproof floors which do not attempt some protection of the ironwork, although in several instances the protection consists only of a suspended ceiling. Fireproof floors, in which a permanent centering is used are constructed with curved sheets of corrugated galvanized iron resting upon the upper surfaces of the lower flanges of the iron joists with concrete filling-in above this centering.

Messrs. William Lindsay & Co.'s floor, shown in Fig. 1, of steel decking with concrete filling-in above, is a floor designed with the view of weight-bearing capability. The under surface of the steel decking and the lower flanges of the joists are unprotected. The concrete used is pumice concrete, that is, it is composed of coke breeze, sand and Portland cement. Where protection to the iron is desired a suspended ceiling can be applied as shown.

Passing on to the consideration of those floors which attempt complete protection of the ironwork, and taking first of all those which require temporary centering, we have a group in which the ironwork is wholly embedded in solid concrete. Of these, Lindsay's system with interlaced tension rods passing over and under the iron or steel joists is illustrated in Fig. 2. The concrete is in this case pumice concrete.

Messrs. B. Ward & Co. have constructed floors under their patent for a steel webbed solid concrete floor, in which the steel webbing passes over the top of the iron joists, and so is embedded in the lower half of the thickness of the concrete. This was one of the earliest forms of floor in which the idea of increasing the tensile strength of concrete by means of embedded metal was adopted. Messrs. W. B. Wilkinson & Co. have also made floors of solid concrete with the joists embedded and the tension iron rods passing over the top of the joist.

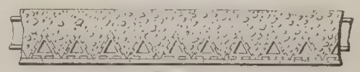

Fig. 13.

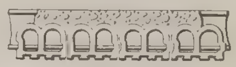

Fig. 11.

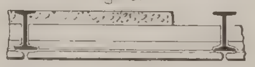

Fig. 12

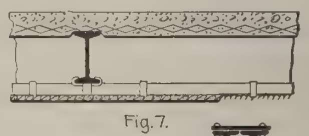

Fig. 7.

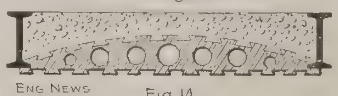

Fig. 14.

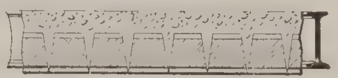

Fig. 15

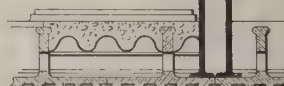

Fig. 16.

The Stuart Granolithic Stone Co. make thin floors in granolithic concrete, with the steel joists embedded in concrete blocks, and using central beams also of granolithic concrete, as shown in Fig. 3. Floors in granolithic concrete have also been constructed in arched form with thin crowns and thickened haunches.

Another group of floors is that in which flat arches between the joists are used, provision being made for the protection of the under side of the joists on which the arches rest. Of constructions of this kind we have examples in the Doulton-Peto floor, illustrated in Fig. 4, in which the arches are built of fire-clay blocks with dovetailed sinkings on the sides to form a key for the cement. Another example is Messrs. Blanchard's floor, in which perforated blocks are used, tied together with iron rods passing through the joists, as shown in Fig. 5. Similar in principle to these are Burnett's floor, Hornblower's, and Northcroft's; whilst Whichcord's system, with solid fire-clay blocks enclosing the lower part of the joists and forming the skewbacks of the arches, may be taken as the parent of these systems of construction.

The United Terra Cotta Co. use arched forms in flat arches similar in principle to those already described in the Doulton-Peto, and cognate systems. The essential feature is that the material of which the hollow blocks are composed is a very light and porous earthenware, obtained by mixing the clay with sawdust before burning.

The more modern examples in this section are to be found in a group of which Banks' floor and the floors made by the Expanded Metal Co. are the best illustrations. In Banks' fireproof floor the steel joists are wholly embedded in the concrete, excepting the under side of the lower flanges, and these are protected by the suspended ceiling hung from the top of the steel joists. This floor is shown in Fig. 6, with the wood centering in position, for the removal of which the hangers to the ceiling are hinged.

The Expanded Metal Co. use their patented material as the basis of several varying forms of fireproof floors. The expanded metal lathing is generally embedded in the lower part of a concrete slab to which it therefore imparts, as do other arrangements of embedded metal, the tensile strength in which simple concrete is deficient. In most of the methods adopted by this company, the concrete slab with the embedded metal lathing is above the joists (as shown in Fig. 7), which are protected by being embedded in concrete, cased around with metal lathing and plastered or shielded by a suspended ceiling. In other instances the joists are themselves embedded in the concrete slab, the metal lathing being placed either below or between the joists. Additional strength for the concrete slab is in some cases provided by arched ribs of channel iron and concrete, either with or without a suspended ceiling.

The hanging arrangement for the suspended ceiling is shown in Fig. 8, the wire lathing being attached to the thin bars by the clips shown. An example of a floor with the joist cased is shown in Fig. 9.

Of floors in which a permanent centering is provided or of which the construction of the floor is independent of any temporary centering, there are a large number of examples that attempt complete protection of the iron or steel joists. In the majority of these floors the lintel principle is adopted in construction rather than the arcuate.

Of these the Fawcett floor is a typical example, the special feature being that the hollow tubular earthenware lintels are arranged diagonally, their own diagonals being at right angles to the line of the joists. The advantage sought by this method is to enable the lintel to cover more completely the under-side of the lower flange of the joist. These tubular lintels form the centering for the concrete which is filled in above as shown in Fig. 10.

Messrs. C. G. Picking & Co.'s interlocking floor is similar in some respects to the Fawcett, but each lintel has two tubes, and projections are arranged at the side to afford the means of interlocking. This is shown in Figs. 11 and 12.

The Shepwood patent floor is an arrangement of flat terra cotta slabs grooved at the edges and fitted to the flanges of small T-iron bearers, which span the distance between the joists. Special blocks are made to cover the lower flanges of the joists and thus a complete permanent centering for the conctrete is formed.

In the most modern type of Messrs Homan & Rodger's floor, triangular lintels are used, passing from joist to joist and resting on the lower flange, the under surface of which they cover. This form is illustrated in Fig. 13, whilst an older type is shown in Figs. 14 and 15.

Messrs. Aston & Son construct a floor, which as will be seen from the illustrations, Figs. 16 and 17, is a combination of flat lintels of T-section and corrugated iron permanent centering. This floor was formerly carried out by

---

[*] Abstract of paper presented to the British Fire Prevention Committee.

[†] 7 New Court, Lincoln's Inn, London.

Willis & Astley, the preceding holders of the patent. Messrs. Aston & Son also construct floors of solid concrete with terra cotta casings to flanges, as shown in Fig. 18. This latter form of floor, of course, requires temporary centering.

Messrs. Potter & Co.'s floor, as illustrated in Fig. 19, is a combination of several ideas. The lower flanges of the joists are protected by clay shields which support corrugated iron permanent centering for the concrete, and in addition there is a suspended ceiling of wire lathing and plaster.

Another example of the lintel system is the Adamant Cement Co.'s floor, in which the lintels are formed of concrete blocks composed of Adamant cement with breeze or other aggregate, and sometimes strengthened by the insertion of steel laths. On these lintels is laid a concrete filling. The lintels are slightly varied in form, one shape being shown in Fig. 20, and another in Figs. 21 and 23.

Approximating somewhat to the lintel form are the floors known as the Mulciber and the Carlisle. The former of these, as will be seen from Fig. 23, consists of loose fireclay blocks, enclosing the flanges of the joists and forming corbels, on which rest the hollow fireclay lintels, serving as the permanent centering for a slight finish of concrete. The Carlisle consists of two hollow tubes between each pair of joists, and the filling in of concrete, of which there is a very small amount, forms the key between the tubes. This is illustrated in Fig. 24. A somewhat similar floor to the Carlisle has been made by Messrs. Picking & Co., as shown in Fig. 25.

In Messrs. B. Ward & Co.'s system of cellular tubes between the joists, as illustrated in Figs. 26, 27 and 28, the especial feature is that the cellular slabs or lintels are formed of gypsum, this being in small pieces.

For domestic buildings and where no great weight is to be carried by the floors, or where the floors are of small spans, various forms of fireproof floors are in use which are specially intended to fulfil these particular conditions. As examples of these we have concrete slabs with expanded metal or other lathing, Edwards' floor of concrete slab with iron rods, and several other similar constructions. There is also the method of using wood beams set diagonally so as to form skewbacks for the reception of concrete arches or slabs.

A method of considerable antiquity, but now very little used, is that in which a floor sometimes flat but more often arched in section, is constructed of plain roofing tiles, and in three or four courses laid in cement and breaking joint, with or without a finish of fine concrete on top. This method has been largely used for corridors and other situations where the floors are of no very great span.

Fireproof floors formed of wood have been introduced, such as Evans & Swain's, which consists of ordinary wooden joists nailed together side by side, thus forming a practically solid floor of wood.

A newly patented floor is Hinton & Day's, in which the space between ordinary floor joists is blocked in solid with wood at the lower part of the depth of the joists. A layer of concrete is sometimes added.

Another class of floors intended to provide a moderate amount of protection or "fire-resistance," includes those in which the ordinary construction of wood-joisted floor is supplemented by pugging on fibrous plaster slabs as carried out by Messrs. Wilkinson, or pugging laid on metal lathing without rough boarding and nailed to the under side of the wood joists. A modified form of Messrs. Ward's cellular gypsum slabs, already referred to above, has been used for affording protection to the under side of an ordinary wooden joisted floor. The protection of ordinary wooden joisted floors is carried out also by various combinations of special fire-resisting plasters, and various forms of special lathing.

Amongst these special plasters may be mentioned Asbestic, Fibrous, Silicate Cotton plaster; Adamant cement, and Robinson's cement. Amongst the special Lathings may be mentioned the Expanded Metal already referred to, and Banks' Helical Lathing, in which flat ribbons are interlaced in lattice fashion but twisted between their interlacings. Jhilmil is a metal lathing in which flat sheets of metal are cut and bent up and down to form projecting strips, thus forming a metal lathing with space for keying. There is also a fire-resisting lathing recently introduced by the Mural & Decoration Syndicate, made of woven iron wire studded at its intersections with terra cotta.

Mention must be made of concretes of special composition for the purpose of resisting fire more thoroughly than ordinary concrete. One of the first introductions of this nature was the gypsum concrete of Messrs. Dennett and Ingle. A more recent introduction is the Boyd-Wilson patent concrete, in which "Kieselguhr" is used on account of its low conductivity.

RIBBED GLASS AND THE DIFFUSION OF LIGHT THROUGH WINDOWS.

Previous to 1883, Mr. Edward Atkinson, President of the Boston Manufacturers' Mutual Fire Insurance Co., began to study the best means of diffusing light through windows and skylights in mills, factory buildings, etc.; and in the year named he submitted a report to the Cotton Manufacturers' Association, together with a suggestion for fixed light and transom windows which has since been widely adopted in mill practice. The windows recommended had no sliding sash and were glazed with thick, rough plate glass. This glass cost more than common glass; but it was less liable to breakage; the sash cost less; the thick glass retained the heat in winter, and the light, though a little less, was much better diffused and no shades were required to keep out the glare of the sun.

About the same time he experimented with various forms of glass for this purpose, including prismatic, corrugated, rough, waved and ribbed glass. He had photographic images taken from each kind, and also from plain glass; and he found that the greatest and most uniform diffusion of light was not derived from prismatic or from angular forms, but from simple ribbed glass in true curves, inverse and obverse, 21 ribs to the inch. This form of glass was fortunately in commercial use for certain purposes, and was also the cheapest type of glass suitable for glazing windows, except the common clear glass. There are no patents on the ribbed glass itself, and it was introduced into mills with very satisfactory results. It soon became evident, however, that more complete research was necessary, and the investigation was placed in charge of Mr. C. L. Norton, of the Institute of Technology. The conclusions reached by Mr. Norton were published about three years ago in Circular 67 of the company; but as many new facts have developed since then, Mr. Norton was commissioned to make a second and still more complete investigation, and this report is now made public in Circular 72 of the Boston Manufacturers' Mutual Fire Insurance Co., which is given briefly as follows:

Mr. Norton started out by decidedly doubting the assertion made, that more light was admitted into a room when glazed with corrugated glass than when glazed with plain glass. But experience has clearly shown that at the rear wall of a room 25 ft. deep the intensity of the light was increased three times by substituting ribbed glass for plain. A similar increase is found on the side walls and ceilings, but on the floor there is a distinct loss near the window. Mr. Norton explains this effect as follows:

> The light entering a room through a window comes, for the most part, from the sky, and has, therefore, a general downward direction, varying with the time and position. Hence the position of the room which receives the most light, ordinarily, is the floor near the windows. But, of we interpose in this downward beam of light a dispersive glass, the light no longer falls to the floor, but is spread out in a broad, divergent beam, falling with nearly equal intensity on walls, ceiling, and floor. We must bear in mind that we gain nothing in the total amount of light entering the room, but we have simply redistributed the light, taking up from the floor that which fell there and was comparatively useless, and sending it in directions where it is of more service. The result of the examination of the various glasses was to show that a finely ribbed or corrugated glass was better than the others, as it gives the widest and most unform distribution. There is no apparent gain in corrugating both sides. Ground glass is barred out, because of its actual loss of transparency, caused by slight amounts of moisture or dust. The ribbed glass about 3-16-in. thick, with 21 ribs to the inch, known now as "factory ribbed glass," is, says Mr. Norton, the best dispersive glass upon the market. When a glass of slightly better appearance is desired, that which is known to the trade as "maze" glass is the best. It is similar to the fine ribbed glass, except that the ribs are not straight, but are bent into irregular figures.

Photometric measurements were made by taking two rooms, one above the other, alike in exposure, shape and size, and comparing the intensity of light falling on similar portions of the two, when one was glazed with plain glass and the other with the glass under examination. Broadly speaking, it was found that the center of the room was as bright when lighted by a window of 1 sq. ft. of ribbed glass as with a window of 3 sq. ft. of plain glass. This was true in all lights; from a bright sunshine to a heavy thunderstorm, and with the windows facing in any direction.

The circular reproduces a number of photographs of the same rooms or objects taken when lighted by plain and by ribbed glass. In each case the greater intensity of light derived from the window glazed with ribbed glass is very apparent. One of the most striking of these exhibits is a pair made by exposing a photographic plate in the bottom of a box, in the cover of which was a round hole, provided with a shutter. One opening was filled with plain, and the other with ribbed glass. When exposed a second or two and developed, the plate back of the plain glass showed a perfectly round, bright spot, proving that the light came straight through the hole; on the plate exposed to the ribbed glass the light was diffused over a large surface without clearly defined margins. As the plate was only 6 ins. from the hole the angle of dispersion in the latter case was found to be nearly 90°.

Mr. Norton says that this ribbed glass is especially useful in the factory, where the question of position of machinery, etc., is usually decided by convenience in setting it up, and the possibility of getting the greatest number of operatives into the smallest possible space. If the man near the window needs a shade he cuts off light from the entire room; but the substitution of ribbed for plain glass does away with the necessity for the shade and benefits, instead of harming, those remote from the window. In the school-room, this soft, even light, leaves no desk or book untouched, and is a great protection to the eyes; its use in laboratories, in libraries, and in art galleries, is also commended.

Factory ribbed glass is best set with the ribs running vertically; as otherwise, when the sunlight strikes it, it is too dazzling for comfort. But it may be used with horizontal ribs in basement and cellar windows, where the brightness of the glass does not matter. In these latter places the full measure of the gain in the use of ribbed glass is best appreciated. The fact that operatives in a mill cannot attend to affairs in the street is an advantage; though it is seriously objected to by the operatives themselves, and Mr. Atkinson suggests that it might be well to have some plain glass in each window on this account. But the real gain to the operatives is the better diffusion of light and the protection from the glare of objects outside; shadows are also less sharp. The ribbed glass also diffuses heat; and while the temperature of the whole room is not changed, the heat from the sun is spread evenly over the whole room, instead of being uncomfortably concentrated on a spot near the window.

The ribbed glass should have its ribs on the inside, for ease in keeping it clean; and where double glass is used the ribs should be crossed and set facing each other. Ribbed glass is made with a wire netting imbedded in it, and it has the same optical characteristics as the ordinary ribbed glass.

Mr. Atkinson, in commenting on this report, says that he finds that the use of ribbed glass on the south side of a mill, subject to full exposure to the sun, does not abate the need of shades in many places. He hopes that a glass may yet be found which will shut out part of the light and diffuse that admitted. Another caution is that in mills, print works, or other places devoted to color work, only the pure white glass should be selected. Many kinds of glass that appear pure white show a distinct greenish tinge, if examined on the edges; and the slightest tint of green destroys all possibility of discrimination in many colors. Mr. Atkinson considers that where windows of the ordinary kind have been bricked up, or guarded with shutters, on account of fire hazard, wire-glass of the "maze" pattern would help to stop the spread of fire and at the same time greatly improve the light. Glass of this latter kind is made by the Mississippi Glass Co., with an agency at 20 Canal St., Boston, Mass.

THE NEW BREAKER AT CRANBERRY COAL MINE, HAZLETON, PA.*

By W. S. Ayres, M. Am. Inst. M. E., Hazleton, Pa.

(With two-page plate.)

The construction of a new breaker at the Cranberry Colliery, Hazleton, Pa., was forced upon the operators, A. Pardee & Co., by a fire which destroyed the entire plant early in January, 1896. The loss included, in addition to the breaker, three boiler-houses and three engine-houses. The breaker-engine and all the machinery in the breaker, including the rolls, screens, jigs, etc., were a total wreck.

Among the things aimed at, in the design of the new breaker which was made and carried out by the writer, were:

1. An arrangement and style of machinery that would be very simple, and enable the coal, as it comes from the mine and is hoisted to the top of the breaker, to descend by gravity through the various rolls, screens and jigs to the storage-pockets without the use of any elevator or device for rehandling. Also, such designs of crushing-rolls as would produce a larger percentage of the larger sizes of coal, and a correspondingly smaller percentage of the smaller sizes, than had been obtained in the old breaker. The special relative arrangement of the dump, rolls, screens and jigs, as adopted, is the conception of Mr. F. Pardee, the Superintendent.

2. The introduction of easy grades and turns in all the chutes that convey the coal from one machine to another and to the pockets, so as to avoid chipping and waste.

3. A design of frame for the breaker that would be very rigid, and at the same time use the smallest amount of material for the strength and rigidity required, and that would also embody the possibility of taking out any piece and replacing it, as, for instance, in repairs.

The detailed description of the breaker now to be given will follow, not the above order, which is the logical order controlling the design, but the successive steps of construction, namely: (1) Foundations; (2) frame of structure; (3) machinery; (4) chutes and connections; to which will be added (5) a statement of results.

Foundations.

The foundations were built of stone laid in cement, one foundation for each post, having a broad base and tapering to a capstone about 2 ft. square. There are, in all, 131 of these pyramidal foundations. The size of the base was determined in each case by the nature of the soil and the load that would come upon the post. A careful calculation was made of the load that would come upon each, comprising the weight of the structure, machinery, coal going through and stored in it, the water in jigs, and the effect of vibrations, wind and snow. Fig. 1 is a plan of the foundations.

Fortunately, the majority of the foundations under the breaker proper, including all those carrying the greater weights and subject to the greater vibrations, were upon rock. Where they came upon clay and hard-pan, one to two tons pressure per square foot was allowed, and the size of the base for each was figured from the weight to be carried by that post.

These foundations were not less than 4 ft. deep, so as to ensure them against frost. Yet at this shallow depth, the pressure per square foot assumed for each was far less than the greatest intensity consistent with the stability of the earth. To allow fully for the vibrations that would be caused by the machinery, when in motion, an intensity of pressure was assumed, representing about half that allowable for the same depth were the structure to remain in absolute repose.

The cement used was the Hudson River Rosendale, mixed one of cement to two of sand. The stone used was a very hard conglomerate, having a probable safe working resistance to crushing of at least 50 tons per sq. ft., this being one-tenth of its probable ultimate strength. To avoid any settling, a bed of about 2 ins. of sand was first put into each pit, and the first course of stone was well rammed into it. Large flat stones were selected for this course. In each successive course great care was taken that each stone should be well bedded upon the one below. Only the hammer was used, however, in dressing, so that stone touched stone with only enough cement between to fill up the irregularities of the bedding-faces and abutting joints. This precaution was necessary, as the cement has a safe working strength of only 3 to 5 tons per sq. ft., while the stone, even though it touches the one under it on only a few small surfaces, has a capacity to resist 500 tons per sq. ft. before crushing. That is to say, in all foundations carrying as much as 125 tons, the small surfaces of contact together must equal an area not less than ¼ sq. ft.

This area is quite easily secured in ordinary hammer-dressing, and, when reinforced by the resistance of the cement, the foundation can be relied upon.

The cap-stones were from 20 to 24 ins. square by 12 to 15 ins. thick, rough-chiseled to a level surface on top, after bedding. The above method was adopted in the construction of the foundations, as giving the least risk of settling, the least mason-work, the least cement, and the least labor.

Frame of Structure.

The old breaker, which was consumed by fire, had been constructed entirely of timber, and according to the old plan for wooden structures, which has been in general use in the anthracite region since the mines were first opened, fifty years ago. It consisted of solid members, braced with the usual short braces, framed together in the usual way with mortises and tenons, and pinned with 1¼-in. wooden pins. All upright pieces were set upon, and mortised into sills, which rested upon long stone-wall foundations. The old structure contained about 1,300,000 ft., B. M., of lumber.

The defects developed in the old structure were:

1. The foundations would settle directly under the posts for want of a base of sufficient size at these points, while between posts the foundations were unaffected and useless.

2. The sill-timbers would crush and rot, and the posts would also rot, causing a very great settling, which, added to the settling of the foundations, would throw the machinery all out of line. This was a very serious matter.

3. The mortises and tenons, particularly those of the braces, formed pockets for water to lodge in. When the pin or tenon was rotted off, only the boxing prevented the timber from falling out.

4. It was impossible, except at relatively great expense, to replace any timber or brace framed with mortise and tenon.

5. In the solid members, such as posts, ties, inter-ties, etc., the centre or heart of the stick was found in many cases to be entirely rotten, even to within an inch or less of the sides.

There was a want of rigidity in the structure, due to the short corner-braces, and to the tendency of those pieces acting as struts to shove apart the joints between ties and posts.

7. The strength of any post depended entirely upon what was left of its cross-section after cutting the mortise.

To meet the evils above enumerated, to avoid the use of large and long timbers, which are becoming more scarce and expensive every year, and to use the timber in its most efficient directions, was the problem; and it was solved in the following manner:

The first of the above evils was met by building an individual foundation for each post, with a base sufficiently large to resist the pressure without settling, as described above under the head of "Foundations."

The second was avoided by not using sills under any part of the structure; and the considerations which suggested remedies for this and for the third, fourth, fifth, sixth and seventh defects, were based upon well-known facts concerning the strength of timber, namely:

(a) The ultimate resistance to crushing of white pine, for example, across the grain, is only about 550 lbs. per sq. in.

(b) The ultimate resistance to crushing in the direction of the grain, or end-wise, is about 5,500 lbs. per sq. in.

(c) The ultimate tensile strength in the direction of the grain, or end-wise, is about 11,000 lbs. per sq. in.

(d) A hollow column is stronger than a solid one of the same cross-sectional area of material; the strength increasing as the hollow space increases.

Other kinds of timber, such as oak, yellow pine, hemlock, etc., have ultimate strengths differing from those of white pine, but they follow the same general law.

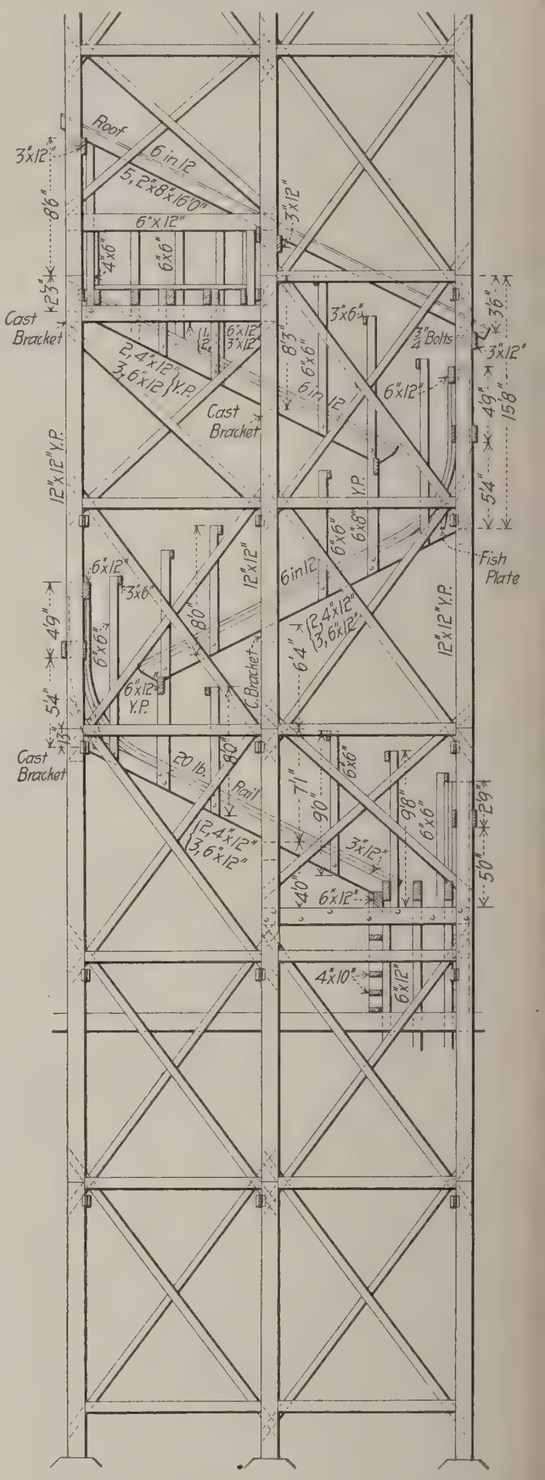

Fig. 6.—Detail of Rock Chute Between Bents 17 and 18.

In view of these facts and deductions, it was decided:

1. Not to place any timber in such a position that it would be acted upon by the load across the grain either in compression or tension, except when this was absolutely necessary, as in the case of bearers under tracks and machinery.

2. To make all braces, as far as possible, act in tension.

3. To build up the posts from ordinary commercial sizes and lengths of lumber, such as can be found in almost any lumber-yard, and to make them hollow.

These points decided, the next step was to design and arrange the machinery in such relative positions, without any reference to the frame, as would accomplish in the best manner the preparation and handling of the coal. Two thousand tons per day of 10 hours was the capacity aimed at.

This done, an outline-design of the structure, having a total height of 200 ft., was sketched about the machinery. Then a very careful calculation, which covered about 100 pages, was made to determine the strain in each piece of the entire structure. This calculation embraced the weight of each machine, the coal running through it, the water in the jigs, all connections, platforms and enclosures, the weight of the roof and snow, the strains due to the wind, and the weight of each piece of timber that entered into the structure. The calculations of the wind-strains in this high structure were complicated, and in some members showed a possible strain of 27.5 tons to be provided against, assuming a wind-velocity of 80 miles per hour.

---

*Condensed from a paper read at the Atlantic City meeting of the American Institute of Mining Engineers. We are indebted to the courtesy of the Institute for the privilege of reproducing direct several of the cuts accompanying the paper.

After the general outlines of the frame and its bracing were sketched around the machinery so as to accommodate every convenience of operation, strain-sheets were constructed from the calculations, and the timbers were assigned to resist the various forces, according to the well-known principles above stated. The result of this by no means trifling labor is shown in the elevation and section of the breaker, Figs. 2 and 3.

The size of each post and strut was determined by Gordon's formula, using a factor of safety of 10, and that of each tie and brace by using one-tenth of the ultimate tensile strength as the safe working-load. To the net sectional area so determined was added whatever would be cut away by the bolt-holes, bolts being used throughout to connect all joints. The number and size of bolts required for each joint was determined by dividing the total strain on the member in consideration by the load one bolt would carry, this load being found by multiplying together the thickness of the timber, the diameter of the bolt and the safe working-pressure per square inch for the timber used. Those timbers which would receive severe shocks (as in the dump, under the rolls, etc.), were increased in size to at least twice the strength required for a quiescent load.

From the elevation shown in Fig. 2, it will be observed that the structure is in two principal divisions; bents 1 to 17 inclusive forming the plane, while bents 18 to 22 inclusive form the breaker proper.

The plane has three tracks with room for the fourth. Each bent is framed as shown in the section through bent No. 8, shown on the left of Fig. 2. The questions of rigidity and of stability against wind-pressure were the most important in designing the plane. To make the structure with sufficient width of base to resist the wind-pressure would require a base so wide that it would occupy valuable ground desired for other purposes. At the same time, the tops of the high bents would have an unavoidable sway, which increases, as shown by experience, the longer the structure is in use. The simple narrow-base parallel bent, shown in Fig. 2, with guy-lines to meet both the sway and the wind-strains, was decided upon. The higher bents were provided with two sets of guy-lines one set attached about 70 ft. from the ground and the other at the top. The wind-strains on these guy-lines, with the wind at 80 miles per hour, is estimated to be 10 tons on each. These guy-lines were grouped in twos and fours at the anchors, which consisted of old railroad-rails, bent like the letter A, with a hook turned on the lower end of each leg, into which was laid a piece of old shafting, and, across the shafting, pieces of old mine-rails. On top of the rails flat stones and pieces of slate from the mines were laid to a depth of 1 foot; and then the earth from the pit was thrown in. Each pit was made large enough so that the weight of earth on top of the anchor would exceed the combined pulls of the guy-lines attached to that anchor. A screw-device for adjustment was attached to each guy-line, and formed the connection with the anchor. These guy-lines are of 1½-in. and 1¼-in. galvanized steel, and were finally adjusted so that the deflection taken out of them by a wind having a velocity of 80 miles per hour, would not allow the structure, when struck by such a hurricane, to sway more than ¼-in. at the height of 165 ft. A hurricane having a 60-mile gait did strike it, July 27, 1896, but without producing any appreciable sway.

The posts of the plane are made of two pieces separated 6 ins., and are butt-jointed every 14 ft. These two pieces are 3 × 10 ins. for bents 1 to 9 inclusive; 4 × 10 ins. for bents 10 and 11, and 4 × 12 ins. for bents 12 to 17 inclusive.

The cross-diagonal braces are 3 × 6 ins. in size, and are entered between the post-pieces, as shown in the elevation of bent No. 8 on Fig. 2. The longitudinal diagonal braces are 2 × 6 ins. in size. Owing to the slender proportions of these braces they will practically act only in tension, a condition which, coupled with the arrangements of the braces at the joint, will pull the joints together, and never tend to separate them. This completely removes the objectional features of the short brace, and at the same time makes each panel a rigid frame, which the short brace cannot accomplish.

The cross-ties and inter-ties are made of two 2 × 8-in. pieces, separated by fillers and joint-pieces. In the cross-ties they are separated 6 ins. throughout, while in the inter-ties they are separated 4 ins. at the center and only 2 ins. at each end.

The mode of framing employed by the contractor was to lay each bent upon skids, placing the various posts, cross-ties and cross-diagonal braces in their exact positions, sawing the post and cross-tie-pieces to a given length, sizing the post-pieces, where the cross-ties came against them, to a uniform distance from the center line of the post, and then laying the whole on the skids, and boring through for the bolts. Next, all bolts were put in, except those, the omission of which would permit the bent to be taken apart in sections for erection.

The plane just described practically continues beyond bent 17, and on top of the breaker proper, from bents 18 to 21 inclusive. The highest part, between bents 20 and 21, carries the three main sheaves for the hoisting ropes. The strain coming upon these three sheaves, amounting to more than 30 tons, is carried directly to the foundations by two struts fastened to the outside of the posts, as shown in Fig. 2. In like manner the main counter-shaft is provided with a vertical strut to resist the jar of the bevel-gears, and with one running diagonally to the engine-foundation, to resist the weight of the shaft, its equipment, and the pull on the driving-ropes, together amounting to 8 tons; also with three horizontal struts, forming the bearers for the counter-shaft, and abutting against the three rows of steel columns in the breaker, to resist the pull on the driving-ropes running from the counter-shaft to the rolls. The object of these devices was to carry the ever-varying and intense strains produced at these working-points directly to the foundations; and the wisdom of it has been shown by the fact that the structure is entirely free from any racking strains or vibrations.

All pieces are of easy access for repairs. For example, to replace any section of a post, the entire weight coming on that post can be taken off by simply slacking the guy-line on that side and tightening the one on the opposite side; and then, by removing a few bolts, the piece is easily removed.

The breaker proper was framed in the same general style as the plane, although some modifications of the cross-ties, inter-ties and bracing were found necessary about the machinery. The majority of the posts are made of two 6 × 12-in. pieces of yellow pine, separated 4 ins. The cross-ties and inter-ties are made of two 4 × 12-in. pieces, separated 4 ins. The fish-pieces, in the cross-ties which come directly opposite each other, run between the post-pieces, and, as one piece, hold the ends of the opposite cross-ties against the post. In cross-ties not opposite, the fish-piece stops at the opposite edge of the post. The inter-ties, all of which come against the side of the 6 × 12-in. post pieces, are cut square and between the posts, and are carried by a cast bracket which forms the connection with the post.

On posts 18, 19, 20 and 21, C. D. and E, the load to be carried is so great that a compact post 2 ft. square would be required for each. A compact or solid post 2 ft. square was out of the question. Therefore, for these twelve posts, steel columns of the Carnegie 12-in. Z-bar type were substituted. These twelve columns carry the greater part of the machinery, and are braced with diagonal braces. They extend from the foundations to the crusher-rolls, and vary in length from 118 to 126 ft. While they cost erected about 1⅞ times the cost of the equivalent wooden posts, yet they have the advantage of greater rigidity and greater durability, in addition to occupying much less valuable space.

The framing of the coal-pockets, eleven in number, for receiving the seven different sizes of prepared coal, each having a capacity of 100 tons, is such that they rest on posts entirely independent of the posts of the breaker. This was done chiefly to avoid adding these 1,100 tons to the already great load of the breaker, and secondly, because it was far easier to provide for their support by using independent posts, giving at the same time far greater advantage for repairs.

A view of the breaker in process of erection is shown in Fig. 4, and a view as completed in Fig. 5.

Machinery.

All coal is hoisted to the top of the breaker direct from the bottom of the mine in 2-ton mine-cars, and is there dumped into a dump holding 25 car-loads. This storage capacity is to insure a regular supply of coal for the breaker against any irregularity in the hoisting. From this dump the coal passes over bars, to sift out the fine coal, and the larger pieces are fed into the crusher-rolls by a regulating feed, or, if lump-coal is to be made, another set of bars is put in over the rolls, and the suitable lumps of clear coal are pulled aside and passed to the lump-coal chute, all other pieces being passed into the crusher-rolls. Just below these rolls the crushed coal and that coming from the bars are mixed, and the mixed product is divided into two equal streams, one going to the prepared-rolls of the east side of the breaker and one to those of the west side; or the whole product can be turned to either set, as desired.

From this point down, the breaker is divided into two distinct parts, exactly alike, each a complete breaker within itself. This is to enable work to continue in one-half of the breaker if a break-down should occur in the other half, or, in running on half-time, to run half of the breaker all of the time.

The product from each set of prepared-rolls is again divided immediately under the rolls, half going to a complete set of screens on the north side and half to a complete set on the south side. At this point, therefore, when both sides are running, the total product is divided into four equal parts, two parts from each set of prepared rolls. Each of these four parts passes directly into a screen, the "over"-product of which is steamboat and broken sizes. The steamboat-size passes to a picking-space and then to the egg-rolls. The broken size passes to a jig, then to a picking-space, and then to either the pocket for that size, or, if not wanted in the market, to the egg-rolls, where, together with the steamboat-size, it is broken down to egg and smaller sizes, which are separated by a special screen, the "over"-products of which are egg, stove, chestnut and pea, all of which pass directly to the pockets without jigging. The "through"-product from this screen passes to a buckwheat- and No. 2 buckwheat-screen, which sizes pass directly to the pockets or to the boiler-house.

At the picking-spaces of the steamboat- and broken-coal the "bony" coal, consisting of pieces that are part slate and part coal, is picked out and passed to a set of bone-rolls. There is one set of bone-rolls and one set of egg-rolls for each side of the breaker. The product from these bone-rolls is divided and passes into the chestnut-screens.

Returning now to the "through"-product of the steamboat and broken-screen, it will be followed to the pockets. It is at once passed to a second screen, the "over"-products of which are egg and stove, which pass to jigs, then to picking-spaces, and then to the pockets. The "through"-product of this egg- and stove-screen passes to a third screen, the "over"-products of which are chestnut and pea, which pass to jigs and then directly to the pockets. The "through"-product of the chestnut- and pea-screen passes to a fourth screen, the "over"-products of which are buckwheat and No. 2 buckwheat, which pass directly to the pockets or to the boiler-house. The "through"-product of the buckwheat- and No. 2 buckwheat-screen passes to the settling-tanks, with the "wash-water."

From the pockets the prepared coal is drawn into cars for shipment. The pockets, eleven in all, have a storage-capacity of 100 tons each, to insure the running of the breaker against any shortage in cars.

The coal, from the time it is dumped from the mine-cars at the top of the breaker until it reaches the cars for shipment, is made to pass from one process to the next by gravity only, no elevators being used. To accomplish this it was necessary to build the structure to the unprecedented and apparently dangerous height of 200 ft.—apparently dangerous because of the wind-pressure and the constant vibrations from the heavy machinery placed so high above the ground.

The capacity of this machinery is 2,000 or more tons of merchantable coal per day of ten hours.

A brief summary of all the machines is as follows, viz.:

Rolls.—1 pair crusher-rolls, 36 × 72-in. shell, fitted with 286 steel teeth in each roll; 2 pairs prepared-rolls, 24 × 48-in. shell, fitted with 280 steel teeth in each roll; 2 pairs egg-rolls, 24 × 36-in. shell, fitted with 520 steel teeth in each roll; 2 pairs bone-rolls, 24 × 36-in. shell, fitted with 2,700 steel teeth in each roll.

Screens.—All screens are of the revolving type.

Four steamboat- and broken-screens, 12 ft. long, with two rings of segments, one 5 ft. in diameter and the other 7 ft.; 4 egg- and stove-screens, of the same dimensions; 4 chestnut- and pea-screens, of the same dimensions; 6 buckwheat- and No. 2 buckwheat-screens, of the same dimensions; 2 egg-, stove-, chestnut- and pea-screens, 18 ft. long, with three rings of segments, 5, 7, and 9 ft. in diameter.

Jigs.—Four broken-coal, 4 egg-coal, 4 stove-coal, 4 chestnut-coal, and 2 pea-coal jigs.

Before passing to the description of the individual machines, a glance at the dump at the top of the breaker, shown in elevation on Fig. 2, may be of interest. In order to hoist to the dump, in 2-ton mine-cars, coal to the amount of 2,000 tons per day, it is necessary to hoist three cars at a time. The cars are hitched together with extra long chains, and the three tracks over the dump are arranged so that the cars, when in position to dump, stand as shown on Fig. 2, thus making room for the coal dumped from a car above to drop into the dump without striking the car below or lodging on its bumpers. In hoisting three cars at a time, it will be plainly seen that there is three times the pull on the hitching-staple at the upper end of the upper car that would occur in hoisting only one car. This triple strain is increased as the cars are pulled over the corrugated track of the dump, and it

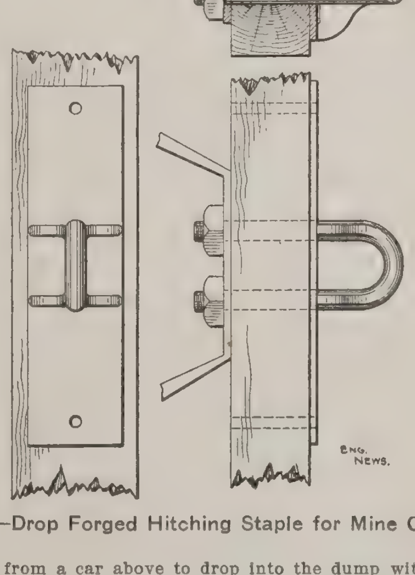

Fig. 7.—Drop Forged Hitching Staple for Mine Cars.

acts in an oblique direction on this staple, alternately up and down, causing a bending-action that would be sure to break the ordinary staple, and cause serious run-aways. Those between the cars are acted upon obliquely also, but with less strain. This danger was anticipated and forestalled by replacing the old staples with new drop-forged steel staples, designed by the writer, having brace-wings, as shown in Fig. 7.

Of the machines, the rolls and jigs play the most important part. The rolls were increased both in diameter and length over those ordinarily in use, and the teeth were made with the points hooked forward in the direction of the motion. The section of the tooth is like the area included between the segments of two overlapping circles. This forms a tooth with rounded sides and cutting edges. The tooth also tapers to a point which looks forward. The rolls of the larger diameter produce a smaller percentage of the small sizes of coal. This is due to the piece of coal being acted upon by the teeth in a way that approximately splits it into pieces. In the old small-diameter rolls, the piece of coal rides on the teeth and is abraded by them before it is pierced and carried through.

The screens are of the revolving type, having a greatly increased screening surface. Eighteen of these are double, having an inner circle of segments 5 ft. in diameter and an outer one of 7 ft.; and all are 12 ft. long. The remaining two have a third circle of segments added, 9 ft. in diameter, and the 5-ft. circle is extended 6 ft., making a total length of 18 ft. for the 5-ft. circle and 12 ft. for the other two.

The jigs are of a special design, patented by Mr. F. Pardee. They are driven by small engines, one for each jig. There are 18 of these jigs in the entire breaker, and, when running full, 2,000 tons of coal per day of ten hours can be prepared with them.

The entire machinery of the breaker is driven by a 30 × 48-in. non-condensing engine.

The transmission of power from the engine to the counter-shaft, and from the counter-shaft to the various rolls, is by a manila rope-drive. From the engine to the counter-shaft ten 1½-in. ropes are used; from the counter-shaft to the crusher-rolls, four 1½-in. ropes; from the counter-shaft to the prepared-rolls, two 1½-in. ropes, and from the counter-shaft to the bone-rolls, two 1½-in. ropes. The egg-rolls are driven by gears from the bone-roll shaft. This arangement of the rope-drive is shown in elevation by Fig. 2.

The entire counter-shaft, and, in fact, the entire rope-drive, except the main driving-sheave at the engine and the sheaves at the rolls, is out of doors, and without any protection from the weather. The weather seems to have some effect upon the ropes to tighten them in wet weather and to make them more slack in dry weather, but the range of this change is not sufficient to give any trouble, provided the ropes are adjusted to the right tension when dry. The first set of ropes was put on in September, 1896, including only five ropes on the main drive from the engine to the counter-shaft, and also only those from the counter to the east-side machinery of the breaker. On July 1, 1897, the west-side was put in operation, and the remaining ropes were put on. All of these ropes are still in operation without renewal.

Many interesting problems were discussed in connection with the selection of a means of transmission of the power of the engine. The counter-shaft is about 85 ft. above the engine-shaft, and so nearly directly over it that it was impossible to count upon any grip on the pulley or sheaves being furnished by the weight of the slack-side of either a belt, a wire rope, or a hemp rope. Therefore, it was necessary to adopt some convenient way to take up all slack and insure a perfect grip.

A leather belt was discarded, because it would be very difficult to keep it at the proper tension without a tightening-pulley, which is a very objectionable device, and also because it would require housing, besides costing about five times as much as a manila rope-drive. A wire rope was found to be uncertain in its grip on the sheaves, and its life could not be warranted. To secure the required grip, a continuous-rope wound system would be required, with a take-up for wear and stretch, which in turn would require some system of differentiation in the grooves of the drum, like the Walker differential drum, to prevent one round of the rope from running away from the others and doing all the work or breaking, a result which may follow a very slight difference in the diameter of the grooves or of the rope. A wire rope-drive was, therefore, out of the question, because of its complications, uncertainty and cost. In like manner the manila continuous-rope wound system was considered and discarded, in view of the objection that if the rope should part for any reason the whole system would be unwound and serious delays would occur in rewinding it.

In the manila individual rope-system were found the advantages of a very low first cost, non-requirement of housing, and ability, if one rope should part, to continue work at once with the remaining ropes. The question of differentiation in the grooves in the manila rope-drive, although the necessity of it exists, is not as serious a problem as in the wire rope-drive, owing to the greater elasticity of the manila rope and to the V-shape of the grooves used. Yet the question arose, how would a new rope work with an old one that is much reduced in diameter by wear? Would the V-shaped groove accommodate this great difference in the diameter of the ropes? It was feared not. The difficulty was solved, however, by the adoption of a shackle and coupling-link like that used by the Philadelphia & Reading Coal & Iron Co., at its storage-docks at Schuylkill Haven, Pa. This shackle is of the ordinary U-shape, is made very short, and has the legs flattened into very thin plates, so as not to increase the diameter of the rope very much. A shackle is riveted on each end of the rope, and the two are hooked together by an open link. This slightly increased diameter at the shackle lifts the rope out of the groove a little as it passes over each sheave, enabling the rope to yield a little toward the side that is drawn too tight. This solved the difficulty of differentiation entirely.

The ropes are shortened, as wear and stretch make it necessary, in two ways. One is to unhook the coupling-link and put more twist in the rope, and the other is to cut off a piece of the rope at one end, and replace the shackle. This is done in the noon-hour, or after-time, but is not a matter of very frequent occurrence after a new rope has received its permanent set. The number of ropes necessary to drive the rolls was doubled, to provide against any delays from the parting of a rope. On the main drive several were added for the same reason.

The diameter of the sheave on the engine-shaft is 20 ft., with 10 grooves in its 22-in. face. On the counter-shaft the main sheave is 10 ft. in diameter, while all others are 6 ft. The speed of the engine ranges from 50 to 60 revolutions per minute, as desired. The speeds of the ropes on the main sheave, corresponding to these speeds of engine, are 3,100 to 3,800 ft. per minute. The screen counter-shaft is driven from the main counter-shaft by bevel-gears, and in turn drives the eighteen 12-ft. screens by means of link-belts. These link-belts have a speed varying with that of the engine from 470 to 565 ft. per minute, and work exceptionally well as a drive in a dusty, dirty place.

Chutes and Connections.

Owing to the great height of the breaker, it was necessary to resort to some special and unusual device for delivering the slate and rock, and some of the coal, from points high up in the breaker to the loading tracks below. Among these will be mentioned only the device in the rock-chute between bents 17 and 18, the spiral chutes from the jigs to the pockets and the spiral lump-coal chute.

The usual way of delivering the waste and the coal to the loading-tracks has been by long, straight chutes, down which the slate or coal runs, at times with a cannon-ball velocity. Turns have frequently been introduced, so as to avoid certain spaces or to gain more distance in which to accomplish the descent. This system requires a great deal of lumber, and occupies a great deal of valuable space, besides having the objection as to the coal-chutes, of chipping the coal badly at every turn, and also where it drops into the pocket. These chippings are small in size and worthless, but their constant production, even in small quantities, reduces in a year, by many tons, the output of the larger sizes of coal, which are most valuable. In the slate- and rock-chutes, however, no such considerations arise, and they usually take the shortest route. One necessity, however, does arise, namely, to provide against the impact of the large pieces at the turns or at the draw. This is usually done by making the timbers at the turns very heavy.

On Fig. 2, in the rock dump, where it turns at the top of bent 12, is shown the device used to avoid the full impact of the large pieces, or of a car-load of mixed sizes, dumped suddenly and moving as one mass. Each car of rock dumped into this chute weighs approximately from 3 to 3½ tons. This device consists of a vertical return, in which the material dumped on the upper section is delivered at an oblique angle against the curved end of the lower section. The force of the impact in this device is only about two-thirds of that produced when the piece is brought against the turn at a right angle. On account of this condition, less timber was used to provide against impact.

This rock-chute down to bent 17 is perfectly straight, but between bents 17 and 18 it makes two horizontal and two vertical turns. These are shown on Fig. 6. The bottom of the chute at each turn is completely covered with 20-lb. rails, laid with the heads up, as in a track, and as close together as the bottom flanges will permit. They are slotted in the flanges, and fastened down with bolts. Such a bottom presents a series of rail-heads to receive the wear, and they are separated about 1¼ to 1½ ins.

When a piece of rock slides down the long, straight part of the chute and enters the horizontal turn it strikes the heads of these rails a glancing blow across their length, and the greater part of its force is expended in passing from rail to rail. Thus the full force of impact is avoided in the horizontal turns. At the lower part of the chute, where the rock and slate are drawn into the dump-cars, there is another horizontal turn, constructed in the same manner. Between these two horizontal turns will be seen, on Fig. 6, two vertical turns which operate in the same manner as the one in the dump at the top of bent 12, above described. Thus a drop of 82 ft. is made in a horizontal distance of 72 ft., and without any destructive shocks.

From the jigs to the pockets, the vertical drop ranges from 70 ft. from the broken-coal jigs to 34 ft. from the pea-coal jig. To convey the coal from the jigs by the usual inclined troughs, or "telegraphs" (a good name for this trough, for the coal often goes through it at almost lightning-speed), would require many thousand feet of lumber, besides which the building would need to be increased by about one-half of its present floor-space to accommodate them. About a mile of these "telegraphs" would have been required. After discussing this method, together with several modifications of it, the possibilities of a spiral chute, or, more correctly speaking, a helicoidal chute, were brought forward and carefully gone over, with the result that, after some hesitation, they were adopted. To determine the correct pitch, so that the coal would neither stop nor run too fast in the chute, was a problem concerning which there were no practical data to be found. From the experience with quarter-turns, both in the old breaker, and also in other breakers in this region, it was decided to adopt a pitch of 3¼ ins. per ft. for the outside circle.

A chute was then constructed as follows:

The outside diameter is 36 ins. and the inside diameter 16 ins. The cross-section is uniform for all sizes of coal from broken to No. 2 buckwheat, the width being 10 ins., and the heights of the sides or flanges 4 ins. for the outside and 2½ ins. for the inside. The chute is made of cast-iron, with four segments to the circle. They are also made rights and lefts. Each segment is provided with four holes in its outer flanges, two at each end, and all are countersunk on the inner side, and are large enough to take an ordinary ⅜-in. chute-nail. These segments, or spiral chute-plates, are nailed between four upright posts of yellow pine, each 4 × 6 ins., and each plate joins the next one at the center of a post. No support is used for the inside edge of the plates. The surface of each plate is made to match that of the one below by a beveled joint, so made that the plate above rests on the one below.

The floor-space occupied by these chutes is very small, being only about 3 ft. square for each chute, and no difficulty occurred in finding space for them.

In the practical operation of this chute it was found that the pitch was not great enough for the smaller sizes of coal, and that the chutes would choke. This was remedied by taking the plates out, and nailing them in again in a tilted position, which gave them more pitch. Since this change, no difficulty has been experienced.

When the machinery was put into the west side of the breaker, from April to June, 1897, a new set of chutes was made, having a different pitch for each size of coal, as determined by the experience on the east side. Only the pitch was changed; all other dimensions were retained.

Between a jig and the place selected for its spiral to go down, a connecting-chute is made of these spiral plates by using alternately a right and left segment. They are nailed to a 12-in. plank that has been stiffened by a backing-piece, 6 ins. wide, set edgewise and spiked to its under side. These right and left plates form a zigzag chute, through which the coal passes without any acceleration. When the coal enters the spiral it at once crowds against the outside flange, and the pieces tend to arrange themselves in a tandem order, forming, particularly in the larger sizes, a continuous stream of single pieces of coal. When the speed increases above a certain amount, each piece leaves the bottom of the plate and runs against the outside flange, where it assumes a uniform speed which is regulated by the centrifugal force pressing it against the side and causing greater or less friction, according to the tendency of the piece to accelerate or retard.

In the pockets the spirals run to the lowest points desired, so that all the coal will be delivered into them without any drop or impact. They are made without any inside flange, and the action of the coal is to slide off the inside edge of the spiral at the immediate surface of the conical mass that is accumulating in the pocket, and to slide down and over its surface. No impact of any consequence occurs from the time the coal leaves the jig until it is at rest in the pocket, and the amount of chippings, therefore, is very small. It is fascinating to see the coal en route to the pockets. First it goes like a snake and then it takes a spin.

The lump coal chute, which begins at the bars over the crusher-rolls, makes a drop of 110 ft. in 78 ft. horizontal. This chute has two sections which are also constructed as spirals. It is shown, in elevation and detail, on Fig. 3, at the right or east side. The same want of data as to pitch, confronted us in the construction of this chute, as in the construction of those just described. It should be clearly understood that the pitch of a spiral does not follow the same law as that of a straight chute. Under these circumstances, and in the anxiety to avoid, particularly in this chute, the usual cannon-ball velocity, the same error was made as to the pitch, that was made in the others. The pitch proved to be not quite great enough. It has not yet been changed to a greater pitch, because lump-coal is not in demand, and, therefore, is not now made. There is no doubt, however, that it will work.

Results.

Foundations.—The foundations are carrying their respective loads without any settling. This is due to the fact that the intensities of pressure assumed to be safely carried by their various parts, are, in practice, within the limits consistent with the stability of the earth upon which they rest, and of the safe working-pressures for the stone and cement used.

Frame of Structure.—In the plane, the advantages gained by the use of the open-member, narrow-base construction, stayed with guy-lines, are briefly as follows:

1. The narrow-base avoids occupying valuable room wanted for other purposes, that would be fully occupied by any self-sustaining broad-base construction.

2. The guy-lines hold the top of the structure perfectly rigid, while in any self-sustaining structure the sway will increase with use.

3. The open members have all the advantages over the solid members, which have already been mentioned in the description of the frame. Prominent among them are:

(a) Greater rigidity of the frame.

(b) The commercial sizes of timber used are cheaper and always obtainable in emergency.

(c) They are more easily inspected.

(d) They will season better and dry out quicker after being wet, and therefore are less liable to rot.

(e) Each piece is easily removed and replaced in repairing.

(f) The open-work in the columns, ties, and cross-ties, and the use of braces acting in tension only, consumes generally about two-thirds of the lumber, for the same strength, that is required by the solid-member construction.

In the plane as constructed, about 127,000 ft. of lumber were used, 24,329 lbs. of bolts and washers, and 5,972 ft. of 1⅛, 1 3-16, and 1¼-in. guy lines.

The saving in lumber as compared with a broad-base self-sustaining structure, built after the same open-member system, is about 100,000 ft.; and, as compared with a broad-base solid member system, is about 200,000 ft. The value of this timber at $25 per thousand, erected, is $5,000. Against this must be charged the guy-lines and their connections (about $800), and the bolts and washers (about $550), or $1,350 in all, leaving as a net saving to the credit of the method used, $3,650, in the plane alone.

In the breaker a similar saving of about 250,000 ft. was effected, which, added to that saved in the plane, makes a total saved in the entire structure of 450,000 ft. of timber. The value of this 250,000 ft. at $30 per thousand, erected, is $7,500, against which must be charged 45,951 lbs. of bolts and washers (about $1,100), leaving, as a net saving, in the breaker, $6,400. This, added to the saving in the plane, gives as the total net saving in the entire structure, to the credit of the method used, $10,050.

The old breaker, which was a smaller structure, contained over 1,300,000 ft. B. M., and the new one just described contains about 900,000 ft., including the equivalent of the steel columns and exclusive of the trestles to the slate-banks.

The contract was awarded to S. D. Kingsley, of Olyphant, Pa., and the entire erection was performed without an accident of any kind. The number of skilled carpenters required was comparatively small. Instead of an army of skilled carpenters at work making mortises and tenons, only a few skilled men were required to direct the assembling of the pieces, to lay off their proper distances, and to mark the positions of the bolt-holes. All of the contractors bidding on the framing and erection were very wary, and even fearful that the structure would not stand up. In fact, some were very pronounced in their disapproval of it. But such views are not now entertained.

Machinery, Chutes and Connections.—All that will be necessary to give here as to the efficiency of the machinery, chutes and connections will be the approximate gain effected by making a greater percentage of the larger sizes of coal and a correspondingly smaller percentage of the smaller sizes. Compared with the old breaker, it is estimated that from 10,000 to 20,000 tons, on a yearly out-put of 300,000 tons, is transferred from pea, buckwheat and No 2 buckwheat to egg, stove and chestnut.

In this comparison it is also necessary to bear in mind that egg, stove and chestnut are the sizes that command the highest prices in the market, while pea, buckwheat and No. 2 buckwheat command the lowest, and lump, steamboat and broken the medium prices. The above gain is accomplished by the style of the rolls, the simplicity of the machinery, the absence of all elevators, and the avoidance, by the use of the spiral chutes, of any impact. The item of saving in labor in the cost of preparation should here be mentioned, as it also stands to the credit of the construction of the breaker, and of the efficiency of the machinery. In the old breaker, to prepare 1,150 tons per day, 194 men and boys, on an average, were required. In the new breaker, to prepare 2,000 or more tons per day, only 84 on an average are required. Mr. Pardee has recently made some important changes in his jig that will in all probability reduce the number of slate-pickers from 55 to not more than 25, and they will be employed only on coal that is not jigged. This will further reduce the total number of men required from 84 to 54.

As to the capacity of the breaker, it has been intimated, under the head of "Machinery," that more than 2,000 tons of merchantable coal could be prepared in a day of ten hours. All calculations and expectations in this direction have been more than realized, and it is now assured that 3,000 tons can be prepared instead of 2,000.

The tendency in the preparation of anthracite coal has been, in recent years, to complicate rather than simplify the process, particularly since the late Eckley B. Coxe read before the Institute his famous paper on the "Iron Breaker at Drifton," in which he described so many ingenious refinements in coal-preparing machinery. In the construction of the Cranberry breaker the greatest simplicity was aimed at, so as to avoid the frequent handling and consequent undue chipping of the coal, the costly repairs on complicated and expensive machinery, and, not least of all, to do the work of preparation with a far smaller number of men.

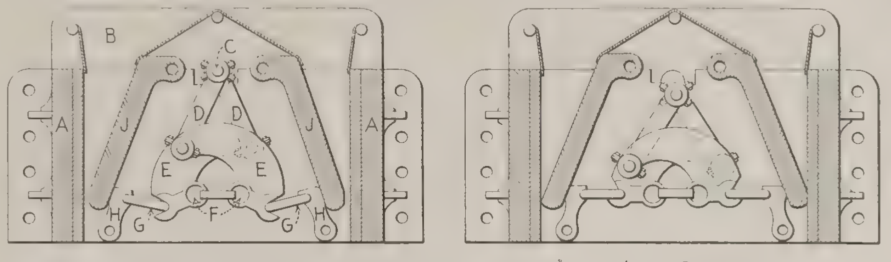
A DOUBLE-ACTING STONE CRUSHER.

In most crushing machines of the jaw or reciprocating type, the crushing is done by a single jaw, but the Preston crusher, which we illustrate herewith, is a double-acting machine, having two sets of jaws at opposite ends of the frame. A general view of the machine is given in Fig. 1, while Fig. 2 shows a sectional view with the jaws open.



Jaws Open. Jaws Closed.

FIG. 2.—LONGITUDINAL SECTION OF PRESTON DOUBLE-ACTING CRUSHER, WITH JAWS OPEN.

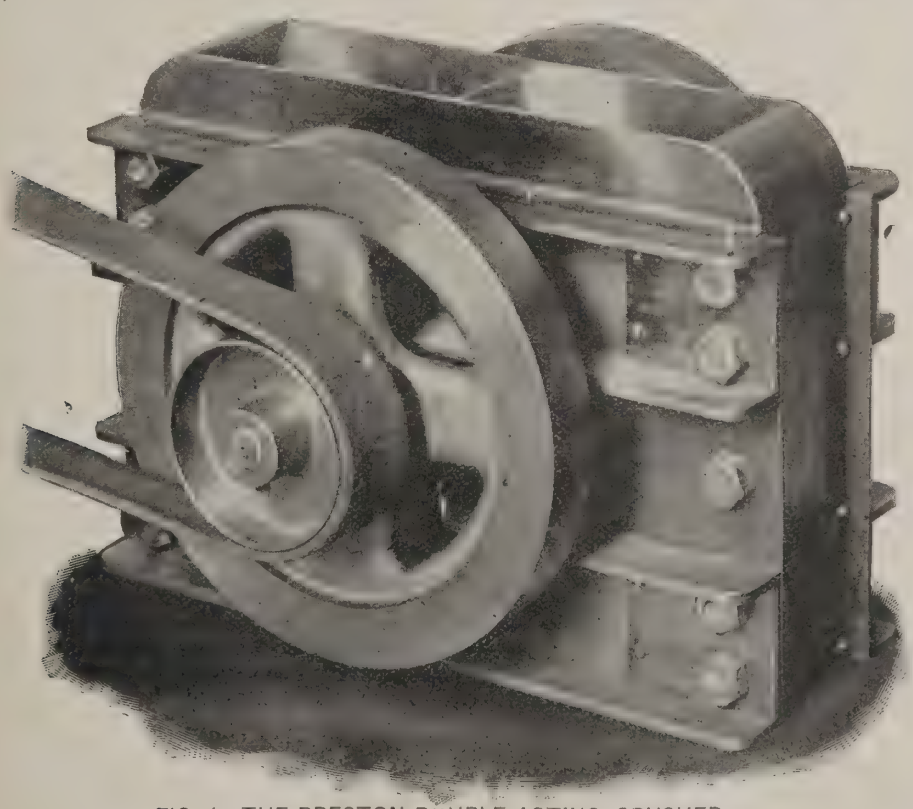


FIG. 1—THE PRESTON DOUBLE-ACTING CRUSHER.
J. C. McEvoy & Co., Beloit, Wis., Builders.

The cast-steel frames, A, are surmounted by a hopper, B, and the crankshaft, C, runs across the tops of the frames. This shaft carries two arms, D, D, to which are attched the levers, E, E, turning in fulcrums, F, F, which are journaled in the frames. In the ends of the levers are inserted the toggles, G, G, which, by means of the pivoted push-plates, H, H, operate the steel crushing jaws, J, J. Great crushing power is claimed for this combination of toggle, lever and crank, and the cranks are so arranged that one jaw is always one-sixth of a stroke ahead of the other.

Lightness and strength are obtained by the use of cast and forged steel for all parts except the two fly-wheels and the belt pulley. In order to fit the machine for transportation in difficult country, for mining and other purposes, it is built up in sections, no part weighing more than 400 lbs., and in case of wear or breakage new parts can easily be applied.

The machine is intended for work in mining districts and for crushing stone for ballasting, macadamizing and other purposes. It is also said to be equally effective for cement and emery works. It may be mounted on wrought-iron trucks if desired, so as to be readily portable. In a test made at the builders' works, a machine having two 12-in. jaws and driven by a 5-HP. motor, readily crushed what are termed "hard-heads" or "iron stone," 7 to 9 ins. diameter, to a 1-in. size, both jaws crushing at the same time.

This crusher was invented by Mr. F. L. Preston, of Beloit, Wis., and is being manufactured by J. C. McEvoy & Co., of Beloit, Wis., to whom we are indebted for blue prints and other information.

A NEW APPLICATION OF THE POETSCH PROCESS, for shaft-sinking by freezing, is proposed for a deep shaft at Harchies, Belgium. The strata overlying the coal measures are 745 ft. deep. The first 170 ft. is made up of dry strata, of blue marl, etc., and the remaining 570 ft. is sand heavily charged with water; the trial borings giving rise to an artesian well discharging nearly 23,000 gallons per hour, and rising 16 ft. above the surface. The engineer proposes to form an ice-wall by freezing from the outside; but as the freezing tubes might be crushed flat and circulation prevented by the enormous pressure developed in the lower strata, he proposes to keep the central boring open down to the coal. The top would be closed and provided with a stand-pipe rising to a height equal to the hydrostatic head at the surface; then, any excess pressure due to increase of volume by freezing would be relieved by the surplus water flowing out at the surface. To prevent the freezing of the pipes in the upper dry strata, he would lead steam or hot water through a ½-in. pipe placed in the central boring and going down to the bottom of the marl deposit. In this method the amount of water flowing from the relief-pipe would be a good indicator of the progress of the freezing process.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; 6 *months,* $2.50; 2 *months,* $1.00. *To all other countries in the Postal-Union: Regular Edition, One Year,* $7.60 (31 *shillings*); *Thin Paper Edition, One Year,* $6.31 (26 *shillings*). *SINGLE COPIES of any number in current year,* 15 *cents.*

In ordering changes of mailing addresses, state BOTH old and new addresses; notice of change should reach us by Tuesday to be effective for the issue of the current week. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 329 *means that subscription is paid to the 32d week (that is the issue of Aug. 10) of the year* 1899; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want notices, special rates see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

We give considerable space in this issue to a description of a coal breaker recently erected at Hazleton, Pa., which embodies some novel features in construction and in its arrangement of the machinery for handling the coal. The most notable is the use of guy lines for securing the structure against wind-strains instead of giving its posts a batter, according to the usual practice.

The use of guy lines as a permanent part of an engineering structure is of course not entirely novel; but in general they have been used only for such structures as tall standpipes, steel chimneys, derrick poles and similar high and slender objects. Their application to hold erect a timber framework, 50 to 150 ft. high, and only 24 ft. wide at the base, is, so far as we recall, unprecedented. We see no reason, however, why their use should not be entirely successful if the strains put upon them under various conditions of loading, tightening, temperature and wind pressure are all correctly determined and provided for. It may be pointed out, however, that such a construction would be much more appropriate with a wooden structure with its large elasticity than it would be with a steel structure, such as a standpipe for example, which is too stiff to accommodate itself to the variation in tension of the guy lines.

A guy rope, like the cable of a suspension bridge, is necessarily a flexible member, and is subject to vibrations, which are especially great when the wind is high. A wooden structure has elasticity enough to accommodate itself to the changes of stress which these vibrations produce. To put the matter in another way, a structure like the Cranberry Mine breaker is held erect against lateral forces, first by the bracing of its frame-work, and, second, by the guy lines. It is necessary that these two systems shall act in harmony, just as in the case of two different systems of bracing in a bridge truss. One reason for the lack of success in the use of guy ropes for stand-pipes may be that the stand-pipe is so stiff that it becomes crippled by wind pressure before the guy line takes its proper proportion of the stress.

The construction of a trunk railway line in Cuba, with branches to the coast, is suggested by Secretary of War Alger on the ground that it would afford employment to thousands who would otherwise be dependent upon charity. Aside from this, however, it is doubtless true that the improvement of the means of internal communication is the first and all-important step in the development of the island. Such an expenditure of public money for charity alone would hardly meet with popular approval; but it is very probable that such a railway would eventually prove a profitable enterprise if it were properly constructed and operated. Cuba now has about 1,100 miles of railway track, connecting Havana with the town of Pinar del Rio, on the west, and Santa Clara, or the port of Caibarien, on the east; but the whole eastern half of the island is without railways, excepting only a north and south line in the Province of Puerto Principe and the mineral roads in the vicinity of Santiago de Cuba. The distance between the latter city and Santa Clara is about 300 miles, and it is to the construction of a main line from Santa Clara eastward and its branches that Secretary Alger doubtless refers.

Cuba is approximately 800 miles long, and from 30 to 160 miles wide, and is thus topographically well adapted for the location of a trunk line which with its branches would provide means of access to the greater part of the island. Its common roads, though abundant upon Spanish maps, can hardly be depended on as feeders to a railway system. As one writer puts it—the art of road-making in Cuba is not a lost art, for the very good reason that it never existed; and the loose character of the soil, combined with a tropical rainfall, convert existing roads into almost impassable quagmires in the wet season, and covers them with thick dust in dry weather. Except in the vicinity of a few large towns there are no roads worthy of the name in Cuba; and this condition has been partly met on large plantations by the construction of light private railways leading to seaports or to stations on railways now in service. As highway construction is expensive in the island, these private railways will doubtless be increased in number for some time to come, as feeders to the main lines from agricultural centers. As a result of the notoriously inadequate transportation facilities under Spanish rule the development of the natural wealth of the country has been very slow, and not more than one-fourth of the island's surface has ever been under cultivation. Although valuable timber is abundant, the export of such timber has never exceeded $220,000 per year, and good timber land at any distance from a railway lately sold for less than one dollar per acre. The characteristics of previous rule in Cuba seem to have been an almost total neglect of local development and an almost prohibitive tax upon such industries as did exist under these conditions. As to the measure of this Spanish taxation, Mr. Wm. J. Clark, in his recent book "Commercial Cuba," tells us that while, in 1894, the total value of the agricultural products of the island was about $85,000,000, the total tax gathered in that year by the "Mother Country" was nearly $23,000,000.

With this tax incubus removed and modern and civilized methods substituted for the obsolete Spanish rule, the future commercial possibilities of Cuba can hardly be estimated. But the better sanitation of large towns and the improvement of ways of internal communication are the all-important first steps, whether undertaken directly by the government, or by private individuals under government control. The latter seems to us the better method; and it would provide equally well for the employment of the destitute. Capital is abundant in the United States and seeks just such investments as Cuba can offer; provided, that the government will insure stable conditions and will hasten, by all practicable means, the restoration of the island to peaceful conditions.

◆

An interesting legal controversy has arisen at St. Paul over the question whether a railway company is responsible for damages done by its trains to a structure crossing its tracks overhead, which is owned and maintained by the city and which was placed there after the railway tracks were built. The accident which gave rise to the controversy is described in our Correspondence department in this issue, and we think it is worth especial notice by engineers as an instructive lesson in the design of viaducts for crossing railway tracks. Derailments are always a possibility in the movement of cars and trains, especially in large yards where switches and frogs are numerous; and an engineer designing any structure to be placed above railway tracks should endeavor, if possible, to so place or so design its supports that they may be reasonably secure against knocking down by derailed cars. It may not always be possible to do this. At times it may be necessary to place slender pillars so close to tracks that a derailed car will be pretty sure to destroy them and bring down the structure which they support. In these days of cheap concrete construction, however, it is generally possible to provide a monolithic masonry support for the columns of sufficient height and weight to withstand the shock of any ordinary collision, and to do this at no large expense. Here, as everywhere, the matter of safety is really a matter of dollars and cents; and if an engineer can show that at a moderate outlay he can make a structure reasonably secure against the danger of knock-downs by derailed rolling stock, he will generally be instructed to do so.

This matter is of interest not only in connection with the removal of highway grade crossings by the erection of viaducts, but as a matter to be considered in the design of railway stations. There are many old-time "through" railway stations where the brick wall which forms the end of the station is supported on a series of slender brick piers between the tracks. Such a structure may stand unharmed for a century; but whenever a derailed car does come along and strike one of these piers, the whole wall is bound to collapse.

The paper on "The Softening of Water by the Archbutt-Deeley Process," which we publish elsewhere in this issue, contains one of the best expositions we have seen of the chemical theory of removing scale forming ingredients from water. It also describes a new process of water-softening which seems to have a considerable advantage over the old Clark process, and which has met with much success in practice in several installations in England. We believe it would be worth while for large steam users in the country to investigate the merits of this process, with a view to substituting it for the "boiler compounds" they have been in the habit of using.

THE NEED OF IMPROVED METHODS FOR EXTINGUISHING FIRE IN HIGH BUILDINGS.

The need of improved methods and apparatus for fighting fires in tall buildings has received a very timely illustration in the partial burning of the 16-story Home Life Insurance Building, in New York city, on Dec. 4 (Eng. News, Dec. 8, 1898). This structure, taking it as a whole, was a good example of modern tall building construction in all the conditions with which firemen may expect to have to deal in fighting fires in such buildings. The amount of combustible contents was probably as small as it can be expected to be in buildings devoted to business purposes. The amount of inflammable wood-work could certainly have been less, but it was no more than is found in most similar buildings. The interior fireproofing acted almost perfectly in preventing the spread of flames from story to story. Indeed, the only broad feature of the fireproof construction which was essentially faulty was the lack of protection against the entrance of the flames from an exposure fire. Notwithstanding all this, it was found impossible, even with the excellent modern apparatus of the New York Fire Department, to combat the flames successfully above the eighth story, and when the fire had once become established above this level it had to be left to burn itself out.

Reasoning inferentially, this practically amounts to saying that the majority of modern tall buildings must be left to their destruction above the tenth floor when once a fire has obtained headway

there. That there is good cause on this account to be dissatisfied with fireproof construction for such buildings, however, no one who studies the facts will believe. Indeed, in this building, and wherever fireproof buildings have been subjected to fire, there has been every reason for the owners to congratulate themselves that their buildings were well fireproofed. The thing which is clearly proven by the Home Insurance Building fire is that the tall building has introduced conditions in the fighting of fires which require improved devices to meet them. It is this phase of fire protection particularly which will be considered here.

The difficulty of fighting fire in a tall building is due to the fact that it is tall, and to nothing else. At over 125 ft. above the street modern fire apparatus is not and cannot be made efficient in fighting fire from the street level. For high buildings, therefore, it must be supplemented by devices for getting water and firemen above this level, as high in some cases as 300 ft. above the street. (There are five buildings in New York city, the "Syndicate," "St. Paul," "American Tract," "American Surety," and "Commercial Cable," which are 309 ft., 308 ft., 306 ft., 306 ft., and 304 ft. high, respectively.) Not only is it necessary to get water in ample quantities and with high pressures to the tops of these buildings, but there must also be means provided for getting firemen with their hose and other paraphernalia to the same points.

For transporting the firemen and their apparatus the stairways and elevators must serve as else. At over 125 ft. above the street modern and their goods under ordinary circumstances. They must operate, however, under far different conditions than they do ordinarily, and should be designed with that fact in mind. Consider first the common staircase as the means of access to the upper floors where a fire is raging. A 50-ft. section of ordinary 2½-in. cotton hose weighs from 56 to 60 lbs., and 250 ft. of 1¼-in. rope weighs 65 lbs. The carrying of either of these loads from story to story is a task which attains pretty serious proportions at any time, and which may, under certain conditions of inconveniently arranged stairways, or obstructions from smoke, become practically impossible, even with a fire of no very great proportions.

That this is not a merely theoretical criticism, a review of the role played by the stairways in some of the recent office building fires in New York city will indicate. In the comparatively insignificant blaze which occurred in the Vanderbilt Building on Feb. 11 of the present year (Eng. News, Feb. 17, 1898), the firemen were overcome by smoke and exhaustion several times in getting the hose from the street to the eleventh floor by the way of the staircase. Neither this stairway nor the adjacent elevator shaft were touched by the flames, and the only obstacles which the firemen had to overcome in surmounting the stairs were their crookedness and the presence of smoke. Again, in the case of the burning of the Temple Court and the Manhattan Savings Bank buildings, the slate treads of the stairways yielded to the heat, leaving the staircase with openings the full size of the tread, which made them impassable. Marble and bluestone, which are also continually used for stair treads, have proved equally insecure when attacked by fire and water. So little confidence, indeed, is felt in such stone treads that a well-known authority on fireproof construction has recently expressed the opinion that the staircase construction in 90 per cent. of our great office buildings would prove utterly unreliable for the use of firemen in the event of a fire of serious proportions.

These are serious considerations, especially as there is no good reason for a construction which is so insecure. The fault is due entirely to the prevalent construction, which is simply to let the stone tread into iron rabbit frames, with no support underneath them. To make the construction safe would require only that an iron plate, of openwork or gridiron pattern if desired, be placed underneath the stone tread and firmly fastened to the frame. Then if the stone broke or crumbled away there would still remain the iron plate, which would afford a safe support for the foot. Obviously also the staircase could be made entirely of metal, as is, indeed, sometimes done. By the exercise of a little taste the architectural aspect of the staircase would not suffer much by such a construction, and where the stairs are used so little as they are in high buildings, the greater insecurity of foothold afforded by cast-iron treads would not cut a very important figure. The metal construction would, if anything, be less expensive, and it certainly would be a great deal more reliable than the ordinary iron frame with unsupported stone treads.

But when it comes to providing access to the upper floors of a tall building, a stairway is about as crude a method for firemen and hose as it is for handling the freight and tenants under ordinary conditions. For this reason safety requires that all high buildings should have constantly present, day and night, some competent person understanding the elevator machinery, fire appliances, etc., who can aid the firemen in reaching the upper levels, and there should be sufficient steam in the boilers at all times to run one elevator. It was the lack of such precautions in the Vanderbilt Building which necessitated the hose being carried up the ten flights of stairs to the floor which was burning, with the difficulties and dangers to the firemen which have been previously enumerated. In the Home Insurance Building fire the one elevator which was running was used to great advantage until the progress of the fire in the upper stories rendered it inoperative. These two instances illustrate clearly the advantages of having elevator service available in the event of a fire, and also indicate the weakness of this service. These are so apparent, indeed, that it leads one to question seriously whether it might not be justifiable to provide in tall buildings one elevator completely inclosed in a fireproof shaft with solid doors which would be used only for freight service and in the case of fire. To ask that the regular passenger elevators should be inclosed is, perhaps, requiring too great a sacrifice of appearance and comfort on the part of the owners and occupants of tall buildings, but something might possibly be done even here to improve the present conditions if the matter were gone at in earnest.

The foregoing questions are, however, of secondary importance to the question of providing an ample water supply under efficient fire pressure on the upper stories of tall buildings. In all but a few such structures it is only fair to say that an attempt is made to do this. Generally it falls far short of its possible success, however, because of the failure to comprehend the full magnitude and character of the conditions to be met. The apparatus provided is too small for its purpose, and this is true not only of the roof tank supply and the interior pipe system and fire pumps, but also of the stand-pipes for the fire department. The full importance of these latter devices in fighting fire high above the ground seems to be very often overlooked. In many buildings they are not supplied at all, and in many others they are entirely inadequate for efficient fire service.

As indicating the importance of such stand-pipes, Fire Marshal D. J. Swenie, of Chicago, who has made a special study of fighting fire in high buildings, urges that they should not be less than 6 ins. in diameter; should have Siamese connections at the street for the fire department; should be provided with check valves, so that when the steamers are attached their force will be added to that of the building's pumps, and that there should be hydrants on each floor and on the roof. Finally, he urges that each floor should have hose connections with the stand-pipe, and sufficient hose to reach the most remote point of the floor above.

The providing of sufficient power to supply the stand-pipe with an ample amount of water under fire pressure, which is included in these requirements, is deserving of particular stress. It requires no small pumping capacity to keep up efficient nozzle pressure on a few of the upper floors alone of a 16 to 25-story building, and a special fire-pump for this service alone, which may not be called into use once in a decade, seems to owners a useless burden. The result is that the pump for the water supply is very often made to serve as a fire-pump as well, and is more than likely to be entirely inefficient to meet the demands when the crucial test of fire comes. A very obvious partial remedy, at least, which occurs to one in buildings where there is hydraulic elevator service, is to have the elevator pumps so arranged that they can be thrown onto the fire service in case of emergency. The provision described for bringing into service the aid of the fire engines is too obviously wise to need much urging. In the case of the building pumps becoming inoperative by the flooding of the basement or by some disabling accident, these fire engine connections afford the only means for getting water to the upper floors.

There is much reason also to urge that the control of the stand-pipe service should be placed entirely in the hands of the fire department in the event of fire, and be subject to the inspection and approval of this department at all times. This would enable the fire department to utilize the stand-pipes in extinguishing neighboring fires, as well as to protect the building in which it belongs. So evident are the benefits to be gained by such a system, in rapidity of getting the hose into service, in the directness and accuracy with which the water can be applied, and in the shelter afforded to the firemen, that the fire insurance interests would be warranted in insisting upon the general adoption of this requirement.

So far we have spoken only of increasing the efficiency of devices already in somewhat common use. There are many competent authorities on fire protection, however, who urge that a still longer step in advance is necessary, and that in all important cities the business section at least should have an auxiliary water supply system for fire protection only. In a recent report to his department, Fire Chief Bonner, of New York, angues in favor of such a system as follows:

> We must realize the fact that the capacity of land engines to force water to great heights has been reached. When greater power is required to force water to meet conflagration, and to great heights, it must be obtained from other sources than the steam fire engines now in use, and there is no system that could better be recommended than the one under sonsideration. There are high buildings in New York that are entirely beyond the ability of the machinery of the Fire Department to force water to the upper stories. It must also be considered that the tall buildings of the present day, as well as the mercantile buildings, are of greater height and cover larger areas than ever before, and that fires will entail great loss if not promptly checked. If the department is not able to control the fire and surround the structures with large quantities of water, there is a possibility that such fires will extend and become great conflagrations. This source of danger can be obviated by adding an auxiliary plant for the use of the department in the form of the underground pipe line, connected to a roof line system, as well as an aerial line, which should connect to all of the tall buildings. This should be fed from the underground system, and also from our city mains, with the aid of auxiliary pumps—electric or steam—located at different points in the city. By the use of the auxiliary pump water could then be forced to the topmost story of any building, no matter how high, as well as to the circuit on the roof line, and would render positive protection against any extensive fire in that section of the city.

Experience with auxiliary pipe systems of this character is not lacking, for the cities of Milwaukee, Detroit, Cleveland, Buffalo and Boston have already adopted them on somewhat limited scales with entire success. It is reasonable to believe, indeed, that where a plentiful supply of fresh water is available, as is the case in the Great Lake cities, such a system of pipes, into which water can be forced by powerful fire boats or from special high-power pumping stations, affords an almost ideal water supply for fighting fires. Where salt water has to be used, as would be the case in New York and other seacoast cities, the matter assumes greater difficulty. Here the danger of destruction to the pipes by corrosion, and the rusting tight of connections, valves and fittings by the salt water may constitute a serious objection, and before the adoption of an auxiliary pipe system at a great expense, this objection will need to be thoroughly investigated.

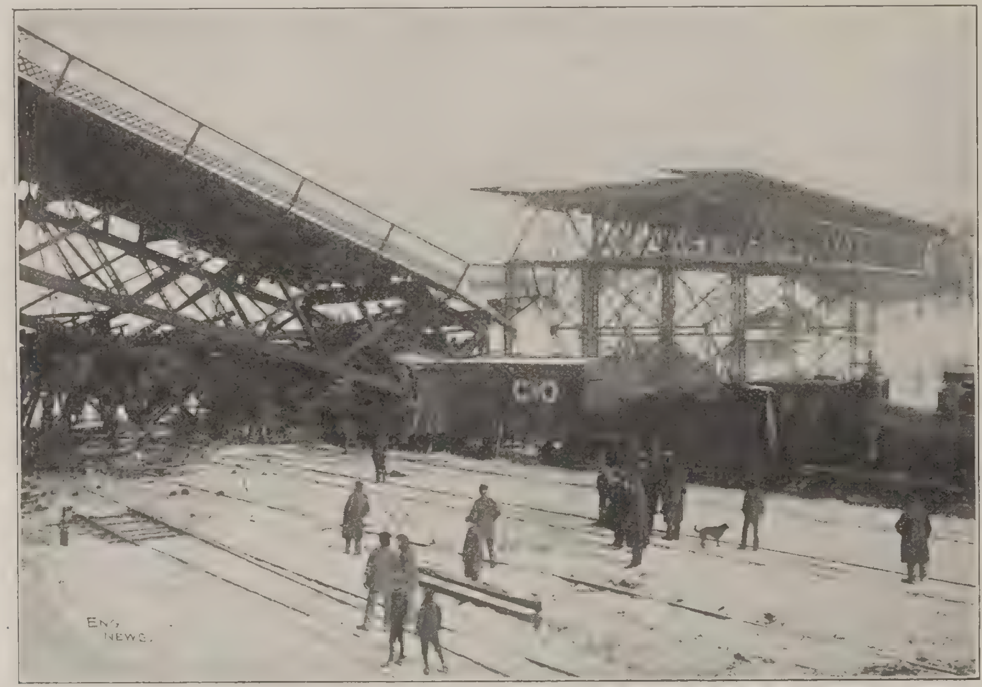
It has been possible in the foregoing to touch briefly upon only a few of the more salient features of the problem of fighting fires in tall buildings. Enough has been said, however, to show that it is a problem which is worthy of careful study by engineers, architects and underwriters. It is also apparent that the erection of a steel framework and covering it with clay tile, concrete, etc., does not create complete protection from damage by fire to the building and its contents, as the non-technical public is too apt to assume.

LETTERS TO THE EDITOR.

Technical Education of Railway Employees.

Sir: I desire to say that I have been requested to prepare a report for the next meeting of the International Railway Congress, to meet in Paris in 1900, on technical education of railway servants, the official wording being as follows:

> Question XXXLV.—Technical Education of Railway Servants; Appointment and Promotion. (A) Attempts made by railway administrations to promote the technical education of their staff. Special schools for the technical staff. Primary schools for the children of railway employees and workmen. (B) Methods of testing the knowledge of railway servants. Appointment and promotion.



WRECK OF THE SIXTH ST. VIADUCT OVER YARDS OF ST. PAUL & DULUTH R. R., ST. PAUL, MINN., DEC. 7, 1898.

(From Photograph taken half-an-hour after the Accident, showing Fallen 100-ft. Span and the Train which Caused the Accident.)

I desire, therefore, to ask any one conversant with the subject to transmit to me as soon as possible full information as to any course of instruction that they may be familiar with, and I shall take great pleasure in acknowledging receipt of the same. As some extended correspondence may be necessary, it is desirable that I have the first information in the immediate future. A reporter on this question has been appointed from each of the European countries, the one from Switzerland being the General Manager of the St. Gothard, and the one from England being Mr. George Gibbs, General Manager of the Northeastern Ry. I presume it would be the desire of all Americans interested in this subject that our report should be as complete as possible.

Very truly yours,

Geo. B. Leighton.

Los Angeles Terminal Ry., 712 Rialto Bldg., St. Louis, Mo., Dec. 13, 1898.

Relating to Mr. Garrels' Pamphlet on "Experiences with an Internal Combustion Motor."

Sir: My good opinion of the Engineering News, to which I have subscribed for a number of years, has caused me to take the trouble to answer a criticism, to which my attention has been called, concerning myself, that appeared in your Supplement of Dec. 8, p. 182. As I believe you do not intend to treat me unfairly, your sense of justice will no doubt cause you to give my reply as prominent a place in your paper as you gave the criticism. My critic thinks we should have taken the matter into court. Permit me to remind him that before doing this it is desirable to have as much relevant information as one can get, and to point out to him that this was my purpose in gathering information concerning this engine, a proceeding which impressed him as being extraordinary. Permit me to say further that it was upon information carefully gathered that we based our opinion that it would be a useless expenditure of time and money to take the matter into court. The writer is under the impression that these facts are brought out in the pamphlet. The uselessness of sueing is surely clearly shown. In the writer's humble opinion the pamphlet is interesting not merely with respect to internal combustion motors, but because it describes the peculiar business methods of certain firms, and this opinion has been confirmed, not only by the large number of letters received inquiring for copies, but by the statements of some men of recognized ability, some of them engineers financially interested in internal combustion motors. My critic's doubt as to the libelous nature of the pamphlet does not agree with the opinion of my attorney. Does the former expect to raise my opinion of technical papers by such a criticism?

Respectfully,

W. L. Garrels.

Franklin Bank Building, St. Louis, Mo., Dec. 14, 1898.

(If any of our readers are further interested in the subject matter of Mr. Garrels' pamphlet we have no doubt he will send copies on application. —Ed.)

Wreck of a Viaduct Over Railway Tracks at St. Paul, Minn.

Sir: I send you herewith photographs of an accident which occurred in this city on Dec. 7. A freight train coming into the yard of the St. Paul & Duluth R. R., at 10:30 a. m., passed a stub switch. The switch was set for the right-hand track, and the engine, one freight car and the forward trucks of the second car passed safely. The switch then turned back, owing to a break in the crank of the switch rod at the stand, and the rear truck of the second car and the balance of the train, some 17 loaded cars, took the left-hand track. The two tracks continue parallel for some distance, and 700 ft. from the switch there stood between the tracks a steel bent supporting a viaduct which carried a street over the railway yards. The viaduct was 60 ft. wide, and the spans whose ends rested upon this bent, were, respectively, 80 ft. and 100 ft. long. The car with its forward trucks on one track and rear trucks on the parellel track struck this bent and knocked it down, and the two spans fell as shown. Luckily but one man was on the wrecked portion of the bridge, and he is in a fair way to recover. The damage to the train was confined to the first and second cars of the train. The principal damage therefore is to the bridge. To rebuild the two wrecked spans would cost about $12,000.

The railway company at this date has claimed that it is not to be held responsible for the accident. The city condemned the street across its right of way and built the bridge at its own risk. The city claim that the railway company so operated its trains and arranged the tracks that it caused the wreck, and therefore it is bound to replace the bridge. At present, the matter stand in this shape, and it is probable that neither city nor railway company will pay for renewing the structure until the courts have passed upon the matter.

Yours truly,

Geo. L. Wilson, Asst. City Engr.

St. Paul, Minn., Dec. 12, 1898.

Estimating Cost of Rock Excavation.

Sir: The estimated cost per cubic yard of excavating rock in a cut, tunnel or shaft is a problem continually presenting itself to engineers. In my own experience this cost varies from less than $1 to $18 per cu. yd. The usual method of getting at the cost is to divide the work under the heads of labor, explosives and tools, and to subdivide these items as may be considered desirable. But while this method will do very well for work performed, it does not apply to work yet to be done; and in the latter case the correctness of the result depends largely upon the experience of intuition of the engineer. Under these conditions the following method of estimating cost is suggested:

To drill and blast a boulder containing one cubic yard will cost not far from 60 cts., and I have assumed this cost as one unit in the calculation. But as the rock to be handled is not always in the form of boulders, but occurs as ledge, or cutting to grades and lines, more or less exactly, the cost is increased by another factor. It occurred to me that working to line in a rock cut was somewhat similar to dressing a stone in a quarry; and as the cost of cutting rough beds on stone was about 20 cts. per square foot, I adopted this as the other factor, and thus evolved the following rule:

To the volume of rock to be removed, calculated as common open quarrying at, say, 60 cts. per cu. yd., add the number of square feet of surface in the bottom and sides of the proposed cut, figured at 20 cts. per sq. ft. This sum divided by the number of cubic yards in the mass will give the probable cost per cubic yard. For tunnels multiply the resulting yard price by two; and for shafts, by three.

A few examples will show how this rule works: Ex. 1.—A rock cut 108 ft. wide by 25 ft. deep measures 100 cu. yds. per lin. ft. of cut; and it has 158 sq. ft. of working surface for the same length unit. These two factors multiplied by 60 cts. and 20 cts., respectively, give $91.60, or 91.6 cts. per cu. yd. Ex. 2.—A rock cut 108 ft. wide and 1 ft. deep measures 4 cu. yds. per lin. ft. of cut, and has 110 sq. ft. of working surface. Calculating again at 60 and 20 cts., we have $22.40, or $6.06 per cu.yd. From the second example we will see that if a mistake is made in leaving the grade 6 ins. too high, it will cost $11.50 per cu. yd. to cut it down this 6 ins., as a separate operation.

As tested by experience the factor prices of 60 and 20 cts. come very near the actual cost in many cases. And contrary to the usual assumption, the hardness of the rock does not vary the result very materially; and it would seem that the dimensions of the cut have much more to do with the cost of excavation than the quality of the rock. I simply suggest this rough rule that it may be further tested by engineers.

Very truly,

John F. Ward.

New York, Dec. 19, 1898.

More Light on the Morgan Bill for the Purchase of the Maritime Canal Company's Concession.

Sir: I have read with great interest your admirable editorial on the Morgan bill, and ask space to make a few comments on the bill and on the Maritime Canal Company. The Morgan bill provides for a board of eleven directors, one of whom shall be appointed by Costa Rica, one by Nicaragua and nine by the President of the United States.

Article X. of the Concession from Nicaragua provides as follows:

> Its board of directors shall be composed of persons, one-half at least of whom shall be chosen from the promoters who may yet preserve their quality as such.

Article XI. reads:

> The Government of Nicaragua shall have the perpetual right of naming one director, who shall be an integral part of the board of directors of the company.

Article X. of the Concession from Costa Rica confirms the same right to Costa Rica. Under the terms of these concessions at least six of the eleven members of the board must be selected by the President of the United States from among the original promoters of the scheme, thus putting the organization of the board into the hands of the old Maritime Canal Co. The bill seems to have been drawn all the way through with this in view. It provides that "the canal *may* be constructed under the supervision of the Engineer Department of the United States Army if the President of the United States shall so direct" (italics mine). "Otherwise the board of directors shall appoint all the engineers in the service of the company."

Why not make it mandatory that the work shall be done under the direction of the Corps of Engineers of the U. S. Army? Are the people of this country willing to turn over to the Maritime Canal Co. $100,000,000 to $150,000,000 to be expended as they see fit? Especially when their annual reports show that they have issued stock and bonds to the amount of $23,471,500, and only claim to have expended from $4,000,000 to $5,000,000.

Under the terms of the bill, the company may default in the interest every year until the maturity of the bonds in 1926, and no steps can be taken to enforce the collection. The lien of the United States on the work cannot be enforced until the maturity of the bonds.

The act also provides that if default is made in the payment of the principal, the United States may take possession, and "thereupon the full and complete title to all such property, rights, privileges, easements, or franchises shall vest absolutely in the United States." This is clearly contrary to Article VIII. of the Concession, which prohibits the transfer to any government. This is not an evasion, but a clear violation of the terms of the Concession.

If the new Maritime Canal Company is to be made up from persons connected with the old one, it behooves the government and the people to examine into their business methods in the past.

We find here a company attempting to carry out one of the largest engineering enterprises of modern times, without ever having had an engineer in their employ. Mr. A. G. Menocal was the chief engineer of the Construction Company; his reports are addressed to them, as is also the report of the Bogart board.

In his statement before the Congressional Committee Mr. Menocal states that he never saw the contract which was said to exist between the Maritime Company and the Construction Company, and yet he was carrying out the work under that contract. The Maritime Company are said to have paid the Construction Company from time to time for work done. How did the Maritime Company verify these accounts? They had no representative or engineer at Greytown. Or were they simply a bureau to charge up whatever the Construction Company presented, and then ask the Government of the United States to take these accounts off their hands for a lump sum ranging from $11,000,000 to $5,000,000, the amount depending on the length of time the Concession still has to run?

Before making any such purchase it behooves the government to untie the bag and view the pig.

The Government of Nicaragua have repeatedly stated that they would prefer to negotiate directly with the Government of the United States, and have the canal built directly as a government work. If this were done and the work were put under the control of the Corps of Engineers of the U. S. Army, there is no doubt but the canal would be well built and there would be no scandal connected with it.

Subscriber.

Some Observations on a United States Transport.

Sir: Apropos of the recent criticism of the War Department, and with special reference to transport ships, the writer was, up to a few weeks ago, in a position particularly favorable for close observation of many of these vessels; a statement of some of the facts of special moment might therefore be of interest to the engineering public. Concerning the chartered vessels much might be said, but it is not intended to consider them here, since their position was peculiar and the "Charter Parties" weak.

It is to six vessels purchased from a Transatlantic steamship company that attention is invited, taking one of these ships in particular as a fair representative of all. It is thought perfectly fair to consider that all of these ships were in very nearly the same condition at the time of their acquisition by the War Department, as all were about the same age and had done about the same amount of work in the Transatlantic trade. All apparently had received about the same amount of attention with respect to maintenance. At the beginning of the peace negotiations between the United States and Spain, one of these six ships was taken out of service and sent to a well-known shipyard for repairs and permanent refitting as a transport, and it was while acting as resident inspector of this refitting that the writer became acquainted with the exact condition of this ship by close personal examination.

It is a modern, twin-screw, steel steamship, 445 ft. long by 49 ft. beam and 39 ft. deep; draft on load water line 26½ ft.; six athwartship bulkheads and double bottom throughout. She has two single and two double-end Scotch boilers and two triple expansion engines of the fore-and-aft type—that is, three cylinders, each working on its own crank. The piston rods of the intermediate and low pressure engines extend up through the cylinder head, and these tail-rods were the most noticeable objects to one entering the engine room. They were so badly cut and fluted that it is hard to see how the ship had run at all, so difficult it must have been to keep any packing in the stuffing boxes. On close examination, nearly all the piston rods and valve stems were found in a varying degree in the same condition, and all had to be turned down to permit the stuffing boxes being packed with metallic packing. This turning down was considerable; one rod, for instance, was reduced in diameter from 4 to 3½ ins.

The valves of the high pressure engines are of the piston type, the others being slide valves. These piston valves were found on removal to be rusted on their faces, showing that the steam had blown freely around them for a long time, and the slide valves were very badly cut in grooves and furrows over ⅛-in. in depth. Another noticeable feature which was an index to the apparent character of the previous maintenance of the ship was the condition of the bearings of the valve gear rock shafts on each engine. These bearings contained an upper and a lower brass, which, in the course of time, had worn away until the bearing was "brass bound"; instead of relining these brasses or properly taking up further wear, a wooden stick had been driven in between the shaft and the upper brass of each bearing. To all appearances these bearings had been in this condition for many months.

Among the auxiliaries the condition of things was very bad. The boiler feed pumps were unfit for any use and the water piston of the principal pump was so much smaller than its cylinder that a large pocket-knife blade could be run all around between it and the sides of the cylinder. In the boiler room probably a little more attention had been given to proper maintenance, as the boilers had been kept fairly clean inside; but some of the boiler mountings, such as drain valves, and some of the stop valves, were so badly corroded that they could be neither opened nor closed without destroying them. Connecting the bilges of the various compartments are gates or sluices in the bulkheads at each side of the ship worked by rods running up to the spar deck. Connected to each of these bilges is a hand pump. Neither the sluices nor the pumps were in working condition, and, to all appearances, no attempt had ever been made to keep them in order.

The tanks in the double bottom, with the exception of the engine tank-head, evidently had not been cleaned for a long time, and probably never. The manhole covers had certainly not been removed within a year. Beneath the ceiling the lower holds were foul with decaying grain, the odor of which filled the lower decks and hold of the ship. This is a ship that for five years previous to last July had carried first-class passengers between New York and London, and then made a trip to Porto Rico, thence to Santiago de Cuba, thence to New York and thence for repairs. While on the voyage to the West Indies the former crew remained with the vessel, and it is reasonable to consider that the vessel did not get into such deplorable condition on the last short voyage.

It is not the intention of the writer to find fault with the War Department for purchasing and operating ships in this condition, because these were practically the only ones available that were at all suitable for the purpose for which they were required, and the urgent necessity therefore was a sufficient excuse. But is there any justification for the management of a Transatlantic steamship company, carrying passengers as well as valuable cargoes, cutting its operating expenses to a point where the engineering department of the company is unable to make a better showing than in the case of the ships referred to above? Is it not remarkable that there are not more "Mohegans" lost at sea?

Yours truly,

Eugene Betts.

New York, Dec. 14, 1898.

◆

A Question in Engineering Ethics.

Sir: I enclose a slip cut from a daily paper published in a neighboring town in this state (Indiana), giving a statement of the business transacted in regular Council meeting. The item speaks for itself, but it may be well enough to call attention to the fact that the company in question publishes a journal ostensibly in the interest of engineers and depends for its support upon the advertisements of this same body of men. Of late several items have been published in the journal upon the ethics of engineering, and some of the experts referred to have been very much exercised over the low standard of ethics in the engineering profession. No further comment is necessary.

Yours,

Oct. 28, 1898. E. A. P.

The clipping enclosed is as follows:

> The Municipal Engineering Co., of Indianapolis, made a proposition to the council through their special representative, Mr. Charles G. Lohman. This proposal embodied the retaining of the company as advisers in all technical questions which will arise in regard to sewerage, street paving, and public improvements of all kinds. The company employs experts in all these lines whose business it is to answer all questions asked by officials of the cities which have retained their services. This saves these cities all the expenses they would otherwise entail by the hiring of experts at such a time. After some discussion the motion was made by Rinehart that the services of this company be retained at the $100 asked by them. The motion was seconded by Kibele, and the roll was called, which resulted in a tie vote. The vote was as follows: Yes, Rinehart, Kibele and Little; nay, Venis, Kreep and Poffenberger.

(In accordance with our usual rule, we submitted a proof of the above communication to the parties criticised, with an invitation to present their side of the case. We append their reply as follows:)

Sir: Both the communication and newspaper clipping, as stated, are erroneous and misleading. Municipal Engineering Co. has not offered or undertaken to furnish engineering service to any municipality. The information service supplied to municipal officials by Municipal Engineering Co. is purely educational, and prepares them for better understanding and appreciation of their need of engineering service, where it may be required. In all cases where there is need of such service, we inform the inquirer that an engineer should be employed, and we advise engineers through our special bulletins to them that there may be opportunity for such employment, but Municipal Engineering Co. does not offer to render this engineering service. Our information service in no way conflicts with the interests of engineers or with professional ethics; it is, on the contrary, helpful in the largest possible measure to engineers, as many of them have realized, and we strictly and faithfully live up to the standard advocated in the articles on engineering ethics in "Municipal Engineering Magazine," referred to by the writer; possibly the writer of the above misleading communication has suffered some from these criticisms. Engineers are among the most zealous advocates of the service referred to, as it in no way unfavorably affects them, but, on the other hand, they profit by it, as information on technical matters, such as we furnish to officials, brings better appreciation of engineering skill.

Municipal Engineering Co.,
William Fortune, Pres.

Indianapolis, Ind., Oct. 31, 1898.

(As we have no desire to give publicity to any "erroneous and misleading" statements, we delayed publication of the above letters and undertook an independent inquiry as to the fact in controversy, viz.: Whether the Municipal Engineering Co. offered to render engineering service to the city in question or not. We addressed inquiries on this point to some of the members of the council of the city referred to in the above newspaper clipping, and have received the following answer:)

Sir: Your inquiry of Dec. 3 received, in regard to the proposition made by Mr. Chas. G. Lohman, representing the Municipal Engineering Co., of Indianapolis, Ind. The company did not offer to render engineering service. Simply that they were at our service as consulting them on any technical question, or would be our advisers for one year if the proposition was accepted. The Municipal Engineering Co. claims to have employed experts on all topics, which would render valuable service in regard to information furnished by them.

Yours very truly,

Cuno Kibele.

Bluffton, Ind., Dec. 5, 1898.

(The question which will doubtless puzzle our readers is: What sort of information or advice did the company propose to render to cities on technical questions that would not be rendered by a competent consulting engineer? We believe we can explain the seeming contradiction which appears in both Mr. Fortune's and Mr. Kibele's letters. A curious idea of engineering exists in certain rural sections. This idea may be expressed by the following definitions: 1. Surveying is making measurements in the field with the aid of a compass. 2. Engineering is making measurements in the field with a transit or a level. Thus the city engineer in many small cities is required merely to make measurements for streets, grades, sewers, drains, etc. That he should be also an adviser concerning the design and construction of pavements, sewers, water supply systems and similar city improvements or should be placed in charge of such work, never appears to be thought of. We may also add that in these same localities the value set on an engineer's services is in close relation to the above idea of his sphere of action.

But, it may be asked, if the term engineering is limited to the purely mechanical work with measuring instruments, what name is given to the real work of the engineer in the design and supervision of construction work—what we may call the "knowing how?" To the best of our knowledge the "knowing how" is not thought to be worth paying for at all in such places. Any alderman is supposed to know how to look after street paving, highway construction, sewers and drains. In case a contract is let for work, the contractor is supposed to furnish the "know how," for nothing.

To return now to our correspondent's original criticism, it is fair to say that in the present unformed state of ethical standards in the engineering profession, we know of no reason why the publishers of a technical journal may not, if they choose, conduct a consulting engineering business; nor why they or any other consulting engineer may not solicit engagements in which the payment will be by the year instead of by the job. The extent to which it would compete with its own patrons is a matter for it to decide for itself. We are somewhat inclined to think that the towns which it may induce to engage its services will be towns which would otherwise be little likely to engage the services of any consulting engineer. In this way it may, as it claims, be doing missionary work for the profession.—Ed.)

◆

Spacing Stiffeners in Plate Girders.

Sir: I have noted with much interest the discussion regarding the spacing of stiffeners in plate girders in several of the last issues of the Engineering News. In Prof. Turneaure's observations on a plate girder with an extensometer, described in the issue of Sept. 22, it might be of some value to know where the extensometer was applied, i. e., whether on the outstanding leg of stiffener angle or on the leg against the web plate, and also whether any reading was made on the same stiffener from the opposite side of girder. Unless readings by the extensometer were made on both sides of the girder, a possible solution for the case of those stiffeners which apparently showed tension instead of compression, might lie in the fact that while the outer edge of the stiffener might be in tension the opposite side of stiffener, and the stiffener as a whole was acting in compression, analogous to a column eccentrically loaded. This is an occurrence which was observed in the course of some investigations made on a girder a year ago by Mr. C. A. P. Turner, described in "The Transactions of the Engineers' Society of Western Pennsylvania, of September, 1897," in which the writer assisted.

One point noted in these observations by means of the galvanometer, was that readings taken on the stiffeners showed them to be in compression, and readings on the web in the path of the diagonal of a Pratt system showed tension, while readings taken outside of this broad belt of the diagonal upon the neutral axis gave no positive or determinate readings. These results seem antagonistic to Prof. Turneaure's statement that, "there is as much reason to suppose that the web stresses follow down the web and up the stiffeners, as in a Howe Truss, as to suppose that they follow the lines of a Pratt Truss." In the galvanometer readings referred to, the galvanometer responded very freely to the application and removal of load, thus seeming to preclude the possibility of incipient failure. Your very truly,

F. G. Skinner.

Minneapolis, Minn., Sept. 29, 1898.

◆

Sir: For trespassing further upon the space in your columns in continuance of the discussion of the internal stress in plate girders, the writer will plead the excuse that the letter of Prof. Turneaure, in your issue of Sept. 22, would, without comment, make the experimental results obtained by the writer appear in a false light, and that, having made several hundred measurements on all parts of the experimental girder illustrated in your issue of Sept. 8, and having checked the general results by three or four different experimental methods, perhaps a more concise statement of the results obtained may lead to a more rational and general analysis of the internal web stress than that presented by the average text-book.

Let us first refer to the analysis of the internal stresses in beams in Rankine's "Applied Mechanics," and we find that the case examined by him is that of a beam of constant section along its length. For such a beam he proves clearly that the principal stresses at the neutral axis are tensile and compressive, acting at 45° with this axis and at 90° with each other. The special case of a beam of a given type of cross section increasing or decreasing regularly in sectional area along its length is amenable to similar mathematical analysis, and the general distribution of the internal stress would vary but slightly from the first case considered, as stated in applied mechanics. The general case of a beam varying irregularly along its length, both as regards area and type of section, is quite a different problem, involving too many conditions to be handled in a general way. Even the special cases, when the variations are at regular intervals with a constant section between are by no means simple and easily analyzed.

Since built sections, when well riveted, act under stress approximately as solid sections, we should consider the built girder with stiffeners as coming under the latter class of beams, and the writer would subdivide such girders into general classes as follows:

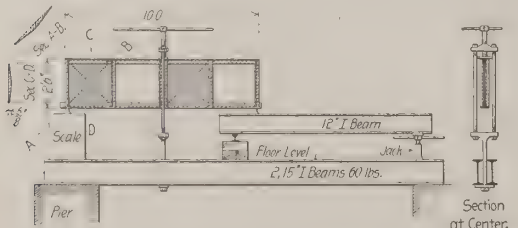

Fig. 1.—Sketch Showing Method of Testing a Plate-Girder to Determine Nature of Web Stresses.

(1) Those girders in which the stiffeners are spaced economically: that is, sufficiently close to prevent buckling of the web and cause it to be capable of fully developing the strength of the flange.

(2) Those girders in which the stiffeners are placed needlessly close together.

Class 1 includes those girders in which the designer has followed Cooper's excellent specifications, in which he requires stiffeners to be placed about the depth of the girder apart, when the shearing stress on the web exceeds that allowed by the formula given. The experimental girder belongs to this class, Fig. 1. The web of this girder was 30 × ⅛-ins. × 10 ft. Top flange, two angles, 3 × 3 × 5-16-ins. Bottom flange, two angles, 3 × 2½ × ¼-ins. Stiffeners at center, four angles, 2⅓ × 2 × 3-16 ins.; all others, two angles, 2 × 2 × 3-16 ins.; fillers ¼-in., rivets ½-in. diameter. Area top flange 3.56 sq. ins.; of bottom flange 2.62 sq. ins. or 2.37 sq. ins. net, practically two-thirds the area of the top flange. Under the usual theory, figuring the experimental girder as though the stiffeners did not affect the internal web stresses, we would have the strain per square inch in the bottom flange about 30% greater than in the top flange, while as a matter of fact it was 6% less. The average deflection noted in a series of readings with the same load repeatedly applied being 25.5 cm. top flange (average both sides); and 24.1 cm. bottom flange (average both sides). This discrepancy can be accounted for only by truss action, as the error of measurement with as expert an instrument man as Mr. Frank McIntyre, who took these readings, would be extremely small.

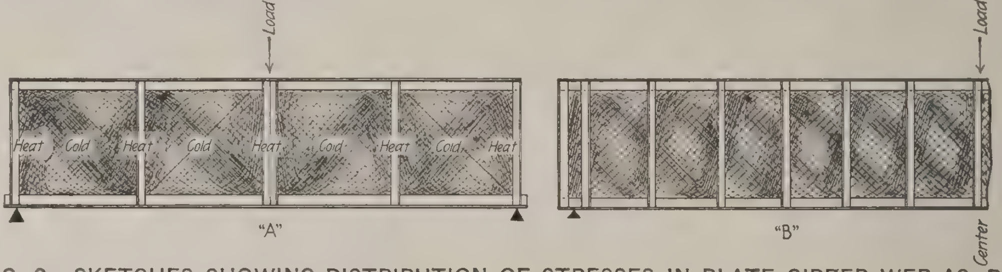

FIG. 2.—SKETCHES SHOWING DISTRIBUTION OF STRESSES IN PLATE-GIRDER WEB AS DETERMINED BY TESTS.

The next proof of truss action, as stated in your issue of Sept. 3, was the springing of the buckled web, which increased gradually with the increase of the load and going back with and apparently proportional to the removal of the load.

The maximum load in this case was insufficient to produce any set whatever, the maximum shear per square inch of sectional area of the web being under 7,500 lbs. and maximum flange stress under 18,000 lbs. per square inch. In this connection also it should be noted that in the panels with the flat web there was no tendency apparent in the plate to wrinkle nor any sign of lateral deflection.

With the thermal junction on the neutral axis of the girder attached to the web plate, either near a stiffener or in the center of a panel, the galvanometer would indicate almost the initial application of the load, the deflection obtained with the junction attached near the stiffener being the reverse in direction of that obtained when the junction was attached in the center of the panel, the wiring remaining the same, thus differing from the I-beam lever on the neutral axis of which we were able to obtain no positive deflection when the load was applied as should be the case under the usual theory. To attempt to account for this result on the ground of incipient failure, when we know the load to have been increased from a few hundred pounds to twenty tons concentrated load on the center of the girder, would indeed be rather grotesque theory.

Finally, the condition of stress, as nearly as the writer is able to determine from several hundred recorded observations, is something like sketch "A," Fig. 2. Here we note:

(1) That the lines of maximum compressive stress in the web are concentrated as it were in the dark area near the stiffeners and that they have changed in direction from 45° being deflected towards that portion of the plate best able to resist compression by virtue of the lateral support of the stiffener angles.

(2) That the path over which the maximum stresses act is but slightly longer than it would be were the tensile and compressive stresses acting at 45° with each other.

It is evident that the intensity of the stresses in the dark area in excess of those in the other portion of the plate are a direct function of the size of the panel, and an inverse function of the thickness of the plate.

Were the stiffeners applied vertically and so close together that the web is practically stiffened all over, it would undoubetedly be in a similar condition of internal stress to the plate of a flitched beam, which the common theory covers exactly. For cases between this extreme condition of excessive stiffening and that of stiffeners spaced economically, as investigated, we should naturally expect intermediate conditions of internal stress. A solution will be offered for one only of these as giving a fair insight to the treatment proposed for other cases.

Referring now to observations (1) and (2) concerning the distribution of stress shown in sketch "A," we may summarize the gist of these deductions in the words of Mr. Buel, that the load seeks the shortest course consistent with the strongest members. Now, under tension, it is true that the strength of a member varies as its sectional area, but under compression, sectional area alone is not the sole factor in determining the degree of strength and rigidity. For example, a 12 × ½-in. plate 10 ft. long would be almost worthless as a strut, while the same sectional area in the form of two 7-in. channels would make a strong and rigid compression member; likewise the stiffener by its form more than by its mere sectional area renders the plate under and near it stronger and more rigid under compression than that portion more removed from it.

Referring now to sketch B, Fig. 2, as in sketch A, we would expect the belts or areas of maximum compression near the stiffener and slightly inclined to it while the belts of maximum tension that act in connection with them in order to fulfill the conditions of following that path which would permit the least vertical deflection of the structure would naturally run to the alternate panel point, this being the shortest path consistent with the condition named that will allow the maximum compressive stresses to follow those portions of the plate which by the lateral support of the stiffeners is best able to resist them.

The point of most interest in this case, with a distribution of stress as outlined, would be that the stiffener would be strained much less than in the first case, sketch A, since the stiffener does not follow the center line of either belt of maximum stress, but lying between them the component of the distortion of the compressive belt along the length of the stiffener being offset in a measure by that of the tensile belt of the maximum stress crossing it at the center.

In sketches A and B, Fig. 2, the writer drew the lines of stress, as they approach the flange, convex towards it in order better to represent graphically his idea of the manner the components of the principal web stresses are transferred to the flange and the condition of strain on the rivets, instead of showing them concave towards the flange, the true position of the lines of principal stress in this portion of the web.

If, with a constant load, we should plot the readings obtained on the web along the neutral axis of the experimental girder, as ordinates with the distances from one end of the girder as abscissas, we would have a sinusoidal curve and the points where this curve passes through the value of $y = o$ would represent the only points where no deflection could be obtained by application of the thermopile when the load was applied. These points lie between the consecutive belts of maximum tension and compression shown in sketch A.

When the thermopile was applied to the plate between the neutral axis and the compression flange heating effect was noted, and the magnitude of this did not appear to increase regularly towards the center of the girder along a line parallel to the neutral axis as it should do were the web stresses uniformly distributed instead of being concentrated in belts, as shown in the sketch. Similarly, cooling effect was noted near the tension flange, indicating the extent to which the web was assisting the flanges in resisting bending.

The action of the stiffener in affecting the distribution of stress in the web plate may be regarded as twofold; first, in rendering the plate in its vicinity better able to resist compressive stress through the lateral support it affords, thus causing an uneven distribution of stress in the web, as shown in the sketch; and, second, under favorable conditions it may relieve the web of a considerable portion of the compressive web stress.

For the former action few rivets are required, but to act efficiently in the latter capacity, where the stiffeners are economically spaced, they should be well riveted as was the case in the experimental girder.

Merely investigating the condition of stress on one side of a few stiffeners in such a girder as selected by Mr. Turneaure would appear on this ground as an insufficient basis upon which to attempt to verify an assumed general analysis of the condition of internal stress of the stiffened plate girder.

As the experiment conducted by the writer is perhaps the first on record in which careful measurements were made of the internal web stresses of a stiffened plate girder, it is natural that some should be inclined to question both the accuracy of the work and the conclusions based thereon. To these, if sufficiently interested, the writer would suggest that as the method used by him is simple and practical, they may readily duplicate the work.

In conclusion, the writer would say that while personally looking after all details of the experiment conducted by him, the work was shared by the following voluntary assistants, all graduates of the engineering schools named, each of whom took his turn reading the galvanometer, taking notes and applying or weighing off loads: Mr. H. A. Kennicott, Massachusetts Institute of Technology; Mr. F. G. Skinner, University of Michigan; Mr. W. P. Rothrock, Pennsylvania State College; Mr. W. S. Huntington, University of Iowa; Mr. J. T. Richards, University of Wisconsin; Mr. Frank McIntyre, Minnesota State University.

All of the above, with the exception of Mr. McIntyre, who is instructor in physics in one of our High Schools, are engaged on structural iron work.

Respectfully yours,

C. A. P. Turner.

Minneapolis, Minn., Oct. 15, 1898.

THE NEW FREIGHT YARD OF THE HARLEM TRANSFER CO., OF NEW YORK.

One of the most unique freight yard arrangements which we have ever seen, has been adopted in constructing the new terminal freight yard of the Harlem Transfer Co., in New York city. This company was formed to establish a railway freight receiving and delivery station for the Harlem River district of the city, and for this purpose it secured the city block at 135th St. and the Harlem River, 330 × 540 ft. in size, the narrower side fronting on the river. This property had been bulkheaded in at various times in the past, and had a slip 100 ft. wide and 200 ft. long. The problem which the engineer was called upon to solve was to develop the property for receiving and delivering freight, either in car loads or in separate packages, the cars to be transferred to and from the various railway terminals in and about the city by the regular car transfer floats.

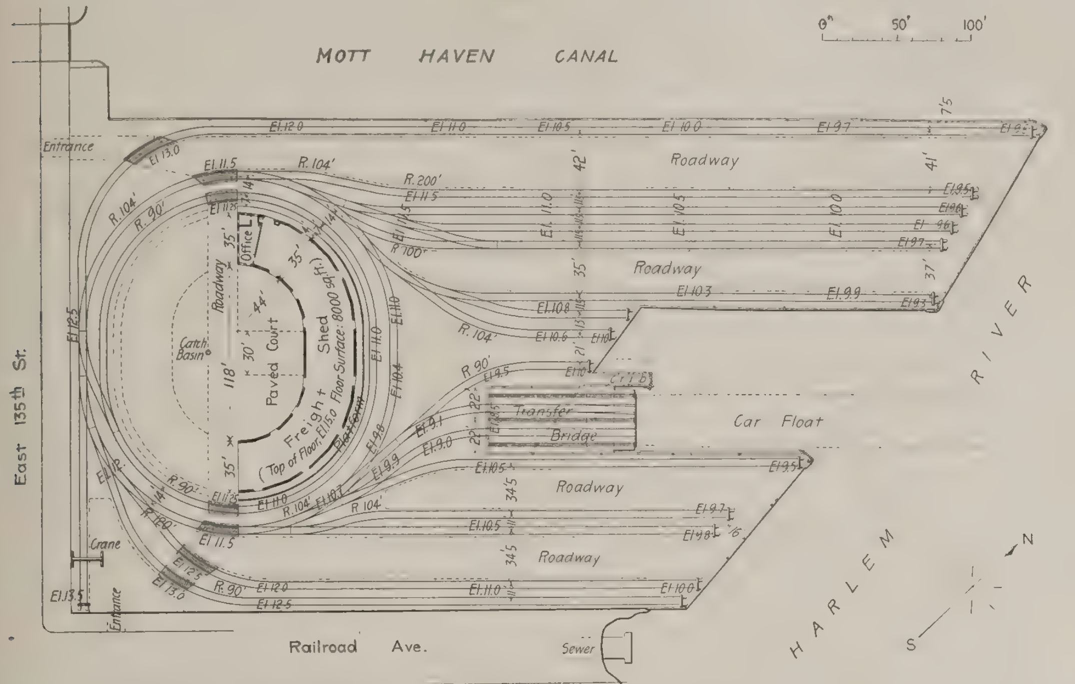

FIG. 1.—TERMINAL YARDS OF THE HARLEM TRANSFER CO., AT 135TH ST. AND THE HARLEM RIVER, NEW YORK CITY.

Walter G. Berg, M. Am. Soc. C. E., Designing Engineer.

The first step was to construct a transfer bridge at the head of the slip. As the standard transfer float adopted by the company was 35 ft. 6 ins. × 240 ft. in size, in order to keep the outer end of the boat when tied up to the bridge within the bulkhead limits, the shore end of the bridge had to be placed within 280 ft. of the line of 135th St., thus limiting the track system to an area of about 280 × 330 ft. The transfer bridge itself is a three-truss wooden bridge, 100 ft. long, the shore end resting on piles and the sea end on a wooden pontoon 40 × 38 × 8 ft.

The leading feature of the design (Fig. 1), however, is the full circle distributing track, from which all side and switching tracks start, and the radial freight house with the inside courtyard for teams. The freight house is an iron frame single story building, 35 ft. wide, on brick piers, and is sheathed with corrugated iron and roofed with tar, felt and gravel. It will be noticed that the loading and unloading track for the freight house is inside and concentric with the circular distributing track, to which it is connected by a switch track. Among the features of this radial or annular form of freight house which the engineer will notice particularly is the great track frontage for a given floor space. Thus the half circle freight house shown in the plan has a car frontage of eight cars with an average actual length of 240 ft., corresponding to six cars. Further, it will be noticed, that by placing the car delivery doors on the outside circle and the wagon delivery doors on the inside circle considerable space is saved. Only one freight shed has been built so far, but it will be seen that the plan allows for the construction of a second exactly similar in all respects, should the traffic demand it.

For switching operations in the yard a special locomotive, built by the Baldwin Locomotive Works of Philadelphia, Pa., is employed. This engine is shown by the accompanying cut, Fig. 2, and its leading dimensions and particulars are as follows:

Switching Engine; Harlem Transfer Co., New York, N. Y.
General Description: Class of traffic............Switching.
Gage of track..4 ft. 8½ ins.; Fuel.............Hard coal.
No. of driving wheels......4; No. of truck wheels,..None.
Simple or compound ....Simple.
Running Gear:
Driving wheels, No........4; Diameter........3 ft. 8 ins.
Wheelbase: Driving ....6 ft. 6 "
Weight in Working Order:
On driving wheels.86,000 lbs.; Engine, total....86,000 lbs.
Cylinders: Number ....Two.
Diameter and stroke..........................17 × 24 ins.
Diameter of barrel, inside smallest ring ....4 ft. 6 "
Thickness, barrel plates ....9-16-in.
Working steam pressure ....180 lbs.
Firebox:
Length, inside, 5 ft. 9⅞ ins.; width, inside ...3 ft. 5⅝ ins.
Depth at front, 4 " ¼ " ; depth at back, ..3 " 9¼ "
Thickness, side plates, ⅜-in.; back plate ....⅜-in.
" crown " ½-in.; tube plate. ....½-in.
Tubes: Number 191
Diameter, outside ....1¾ ins.
Length over tube plates ....8 ft. 3½ ins.
Heating Surface and Grate Area:
Heating surface, tubes (interior area)........718.03 sq. ft.
" " firebox .... 80.11 "
" " total ....798.14 "
Grate area .... 20.2 "

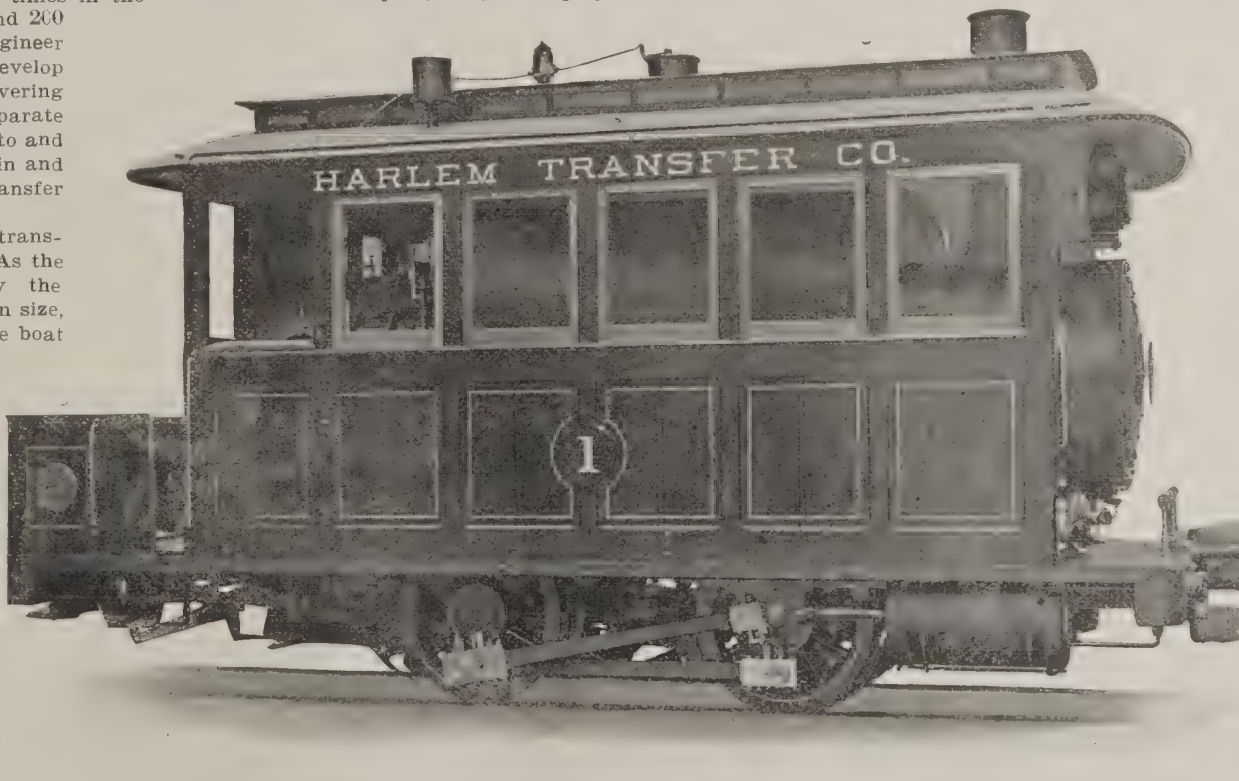

FIG. 2.—FOUR-COUPLED SWITCHING LOCOMOTIVE FOR THE HARLEM TRANSFER CO.

Baldwin Locomotive Works, Philadelphia, Pa., Builders.

For the information from which this article has been prepared we are indebted to Mr. Walter G. Berg, M. Am. Soc. C. E., Assistant Engineer, Lehigh Valley Ry., Jersey City, N. J., who designed the terminal, and to the Baldwin Locomotive Works.

NOTES FROM THE ENGINEERING SCHOOLS.

Cornell University.—The address by President Schurman at the 30th annual commencement, June 16, 1898, entitled "A Generation of Cornell," has been printed in a handsome pamphlet with red line borders and broad margins by G. P. Putnam's Sons, New York city. The address covers the history of Cornell from 1868 to 1898, and a remarkable history it is; that of modest beginning, of struggle for life, of weary years of waiting, and then of rapid progress to the proud position the University now holds, that of being one of the leading universities of the world. The address is worthy of preservation by every Cornellian, and by all who are interested in American educational history.

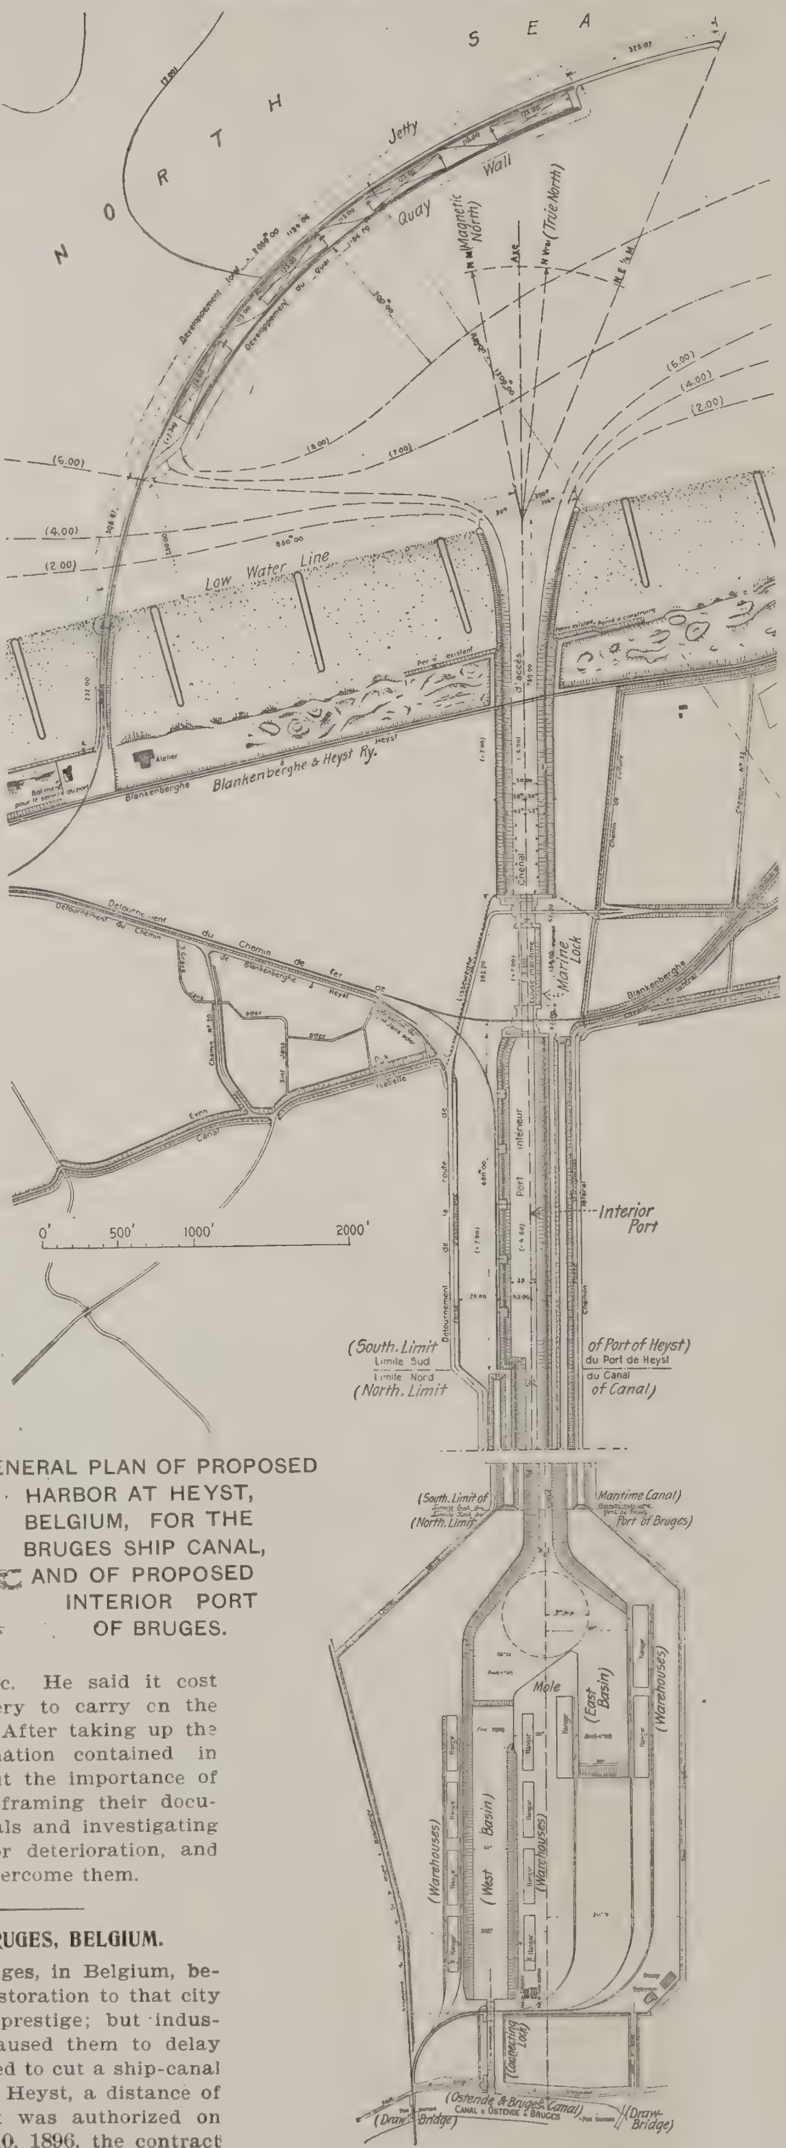
We have also received a pamphlet containing the sixth annual report of President Schurman, 61 pages, with an appendix of 100 pages, giving the reports of the deans of faculties, the register, librarian, etc.

Massachusetts Institute of Technology.—An illustrated descriptive circular, issued by the department of mechanical engineering, gives, among other things, tables showing the present occupation of all graduates of the department since 1868. There are 389 living graduates of the department of mechanical engineering, and but four of these are unaccounted for. Definite occupations are stated for the balance. Over 90 per cent. are employed in work for which they received special training at the Institute, and most of the remainder are engaged in pursuits demanding some scientific training. The Institute has established a special course in architectural engineering, offered as an option in the course in architecture. This course is to meet the demands created by the development of steel construction in the last ten years, and the course is adapted to the solution of the many new and difficult problems thus presented to engineers and architects.

Lehigh University.—An address on "Origins and Destiny," delivered on Founder's Day, Oct. 13, 1898, by Langdon C. Stewardson, Chaplin of the University, has been printed in pamphlet form. It is a highly philosophical and somewhat metaphysical discourse, but is interesting reading, and contains many good thoughts well expressed. It has some thoughts on "science," however, which seem rather to belong to the philosophy of the Keely motor than to the science of ordinary mortals, such as the following:

> It is not Phillip Brooks, but Professor Brinton who says, "The teachings of the severest science tells us that matter is in its last analysis motion, and that motion is naught else than mind; and who dare deny that in their unconscious functions our minds may catch some overtones, as it were, from the harmonies of the Universal Intelligence, thus demonstrated by inductive research, and vibrate in harmony therewith?"

Purdue University.—"The Relation of Chemistry to Railroads" was the subject of the opening lecture in the University course, delivered by Dr. Charles B. Dudley, Chief Chemist of the Pennsylvania R. R. Co. In connection with the amounts of money expended by railways for materials, he said the Pennsylvania Railroad spent from $17,000,000 to $20,000,000 annually on this account. Of this aggregate, about $5,000 was expended for rubber-bands, $7,000 for lead pencils, $1,000 for pins, $5,000 for ink, $2,000 for toilet soap, $1,000,000 for lumber, $60,000 for hose, etc. He said it cost nearly as much for stationery to carry on the business as it did for iron. After taking up the specifications and the information contained in them, Dr. Dudley pointed out the importance of the duty of the chemist in framing their documents and in testing materials and investigating difficult problems of wear or deterioration, and the suggestion of means to overcome them.



GENERAL PLAN OF PROPOSED HARBOR AT HEYST, BELGIUM, FOR THE BRUGES SHIP CANAL, AND OF PROPOSED INTERIOR PORT OF BRUGES.

* * *

THE SHIP CANAL OF BRUGES, BELGIUM.

In 1877 the citizens of Bruges, in Belgium, began to plan means for the restoration to that city of its one-time commercial prestige; but industrial and other conditions caused them to delay until 1890, when it was decided to cut a ship-canal from Bruges to the coast, at Heyst, a distance of about six miles. The work was authorized on Sept. 11, 1895, and on Jan. 10, 1896, the contract for its execution was let to the Campagnie des Installations Maritimes de Bruges. From a pamphlet issued by this company for the International Congress on Navigation, held this year at Brussels, the following description of the canal is abstracted:

The port of call at Heyst is made up of a jetty, alongside of which ships can lay; an anchorage and protected harbor, a canal with a marine lock and an interior basin with docks. The jetty leaves the shore about half way between Heyst and Blankenberghe, and forms a curve with radii of 3,936 and 6,560 ft., and at the end the direction is about parallel with the coast line and 2,788 ft. distant at low tide. This jetty has in it an opening, extending 984 ft. beyond low-tide mark, intended to facilitate the movement of the shore currents and prevent the deposit of silt and sand in the harbor. Over this opening a railway is carried on a steel trestle structure with bents 16.4 ft. apart, and this bridge terminates at an abutment of masonry founded by the aid of compressed air.

The outer part of this jetty is a solid curved structure, protected by a high sea-wall. The base of this portion is made of monoliths of beton weighing from 2,500 to 3,000 tons, deposited in iron caissons, each 82 ft. long and 29.6 ft. wide and of a height varying with the depth of the water. They rest upon a sand bottom previously dredged to a depth of about 13 ft., and the tops of the caisson blocks rise to a height of about 3.28 ft. above low-tide. Upon this base is built a wall of 50-ton concrete blocks; this wall being 16.4 ft. thick and 24 ft. high above low-tide mark; an outer parapet wall, 3.28 ft. high, protects the top of the jetty. The jetty terminates in a pierhead, 50 ft. in diameter, upon which a lighthouse and the fog siren are established. Under the shelter of this jetty, and at a distance 177 ft. between centers, is built a parallel quay wall, having a total length of 3,562 ft., and constructed in a similar manner, of 3,000-ton foundation caissons surmounted by a wall of 50-ton blocks. The space between these walls forms a quay, upon which are railways, warehouses, cranes, etc., for the rapid handling of goods at this port of call. Inside this quay there is a depth of water of 26.24 ft. at low-tide over a space of 984 ft. wide.

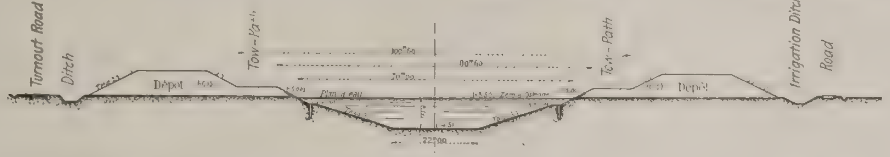
From this harbor a dredged channel 2,460 ft. long, leads to the sea-lock, or entrance to the ship-canal. This channel has an opening 656 ft. wide, a normal width of 164 ft. on the bottom, and a depth of 19.68 ft. at extreme low tide. The lock is 65.6 ft. wide and 518.24 ft. long between gates and 839.7 ft. long over all. The gates roll into opening built at right angles to the axis of the lock proper, and the lock can be closed or opened in 10 minutes. Electricity is used to operate the gates, cranes, etc., and to light the harbor; and a central station, equipped with 500-HP. boilers and engines and two generating dynamos, will provide all the power now necessary. Before completion this port will also be furnished with a repair shop, a floating crane of 55-ton capacity and a large marine dredge.

The so-called interior port of Bruges commences at the inner end of the lock and includes two basins parallel to the canal axis and separated by a mole 393 ft. wide. The West Basin is 1,771 ft. long and 21.3 ft. deep; the East Basin is somewhat shorter, and is 26.24 ft. deep, and both basins have a surface width of 295 ft. At the shore end of the West Basin is a lock uniting the new port with the Ostend canal system. This lock is only 39.4 ft. wide and 564 ft. long over all, and has a depth of 14.7 ft. over the sill. Warehouses will be built upon the central mole, and movable cranes, of 3,000 lbs. capacity, will command the whole length of the dock front.

Progress upon this work, to the present date, is reported upon as follows: The work was ordered on Sept. 11, 1895, and was to be completed in seven years, or on Sept. 11, 1902. The Campagnie des Installations Maritimes de Bruges, which obtained the contract, has a capital of 9,000,000 francs, and is itself interested in the completion of the work, as the following statement of cost and capital contributed shows:

	Francs.
Construction company interest	6,900,000
State of Belgium	26,810,620
Province of West Flanders	2,000,000
City of Bruges	3,258,446
Total	38,969,075

The City of Bruges actually contributes more than appears in the above statement, as it owns one-half, or 4,500,000 francs, of the capital of the construction company. The contractors are themselves interested to the extent of 3,500,000 francs, and the West Flanders railways and some Bruges manufacturers have contributed altogether 1,000,000 francs. At the present time the work is being actively pushed. The ship canal is diked, and is now being dredged out; the interior port is being cleared for the excavators; but the most active work is at the jetty and port, and it is expected that both the jetty and the sea-lock will be finished in 1899. The publication from which this is taken does not enter into details of jetty or lock construction.



TRANSVERSE SECTION OF PROPOSED SHIP CANAL CONNECTING THE HARBORS OF HEYST AND BRUGES, BELGIUM.

THE SOFTENING OF WATER BY THE ARCHBUTT-DEELEY PROCESS.[*]

By Leonard Archbutt.[†]

Hard water owes its peculiarities to the presence of compounds of lime and magnesia, chiefly the carbonates and sulphates, but occasionally also the chlorides and nitrates.

Distilled water, from which every trace of carbonic acid has been expelled by boiling, can hold in solution only about 1.3 grain of carbonate of lime per gallon; but if the water be saturated with carbonic acid it can dissolve as much as 60 to 70 grains, the whole of which, except the above 1.3 grain, is precipitated when the water is boiled and the carbonic acid expelled. All natural water contains carbonic acid, and therefore all such water which has been in contact with chalk contains carbonate of lime in solution.

The use of slaked lime, or hydrate of lime, for softening chalk water[‡] was first proposed by Thomas Henry, F.R.S., about a century ago. The lime removes from the water the dissolved carbonic acid, combining with it to form carbonate of lime, which precipitates, and the carbonate of lime previously held in solution by the carbonic acid precipitates also, leaving the clear water soft. The late Dr. Thomas Clark, of Aberdeen, in his celebrated patent in 1841, described the method of ascertaining the necessary amount of lime by determining the alkalinity of the water; and also the method of controlling the process on the large scale by the simple and delicate test with nitrate of silver, which indicates, by the brown color of the precipitated silver oxide, when the slightest excess of lime has been added. This test fails, however, where, as occasionally happens, the water contains sulphuretted hydrogen. Clark's process in its simplest form is perfectly applicable to but few waters, namely, to those only of which the hardness is due entirely to chalk. It also requires large and expensive settling tanks to carry it out unless filters are employed.

Carbonate of magnesia, though much more soluble in water than carbonate of lime, is usually met with in smaller proportion, seldom exceeding, according to the author's experience, 5 or 6 grains per gallon. Occasionally he has found 10 or 11 grains; and in one instance the exceptional quantity of 28.8 grains per gallon. Carbonate of magnesia can easily be removed from water by treatment with lime; but as it is much more soluble than is usually supposed in water quite free from carbonic acid, merely adding enough lime to remove the carbonic acid will not suffice; it is necessary to add a sufficient excess of lime to decompose the carbonate of magnesia and convert it into hydrate of magnesia which is almost insoluble in water; thus,

$$\mathrm{Mg\ CO_3 + Ca\ (OH)_2 = Mg\ (OH)_2 + \underset{\text{(insoluble precipitate).}}{Ca\ CO_3}}$$

As magnesia reacts like lime with a solution of nitrate of silver, this test does not show when sufficient lime has been added to decompose the whole of the carbonate of magnesia; and it is partly on this account that, when such waters are treated by Clark's process, the removal of the carbonate of magnesia is frequently incomplete. There is also another reason. Magnesia, when set free by lime water, has a tendency to remain in a state of semi-solution, forming an opalescent liquid which may be kept for several days, and even heated, without the magnesia precipitating; and when an attempt is made to filter water in this condition, the magnesia separates out as a gelatinous precipitate in the pores of the cloth, completely choking them. On this account, the softening of water containing both carbonate of lime and carbonate of magnesia is frequently limited to the removal of the carbonate of lime; and the carbonate of magnesia is purposely left in the water. Owing to the practical impossibility of filtering out the magnesia, the hardness of the water can be reduced only from 18.5° to 10° or 12°;[||] but it has been proved by experiment that by doubling the quantity of lime, and precipitating in plain tanks by the special method about to be described, the extra hardness can be further reduced to 6°, and the extra cost for lime is balanced by the saving in the cost of filter cloths, etc.

Sulphate of lime, or calcium of sulphate, which is one of the most objectionable constituents of boiler water on account of the hard crystalline scale it produces, does not owe its solubility to the agency of carbonic acid, but is dissolved by the water itself. It is an exception to the general rule that hot water dissolves more of a substance than cold water. The solubility, it is true, increases from 32° F. up to about 104° F.; but above this temperature it diminishes, at first slowly, then rapidly, and finally more slowly again, as shown by the following Table I., and the diagram Fig. 4:

Table I.—Solubility of Sulphate of Lime in Pure Water.

Observer.	Temperature. deg. F.	Corresponding pressure above atmosphere per square inch. lb.	Sulphate of lime (anhydrous) dissolved by 1 gallon of pure water. grains.
Marignac[*]......	32.0	..	133.0
	68.0	..	144.2
	104.0	..	149.8
	140.0	..	145.6
	176.0	..	136.5
	212.0	0	121.8
Tilden and Shenstone[†]....	284.0	37.8	54.6
	324.5	80.8	39.2
	356.5	132.0	18.9
	473.0	513.5	12.6

It is commonly stated, apparently on the authority of Sullivan,[†] that sulphate of lime is quite insoluble in water at a temperature of 302° F., equivalent to a boiler pressure of 55 lbs. per sq. in.; but Tilden and Shenstone's experiments in Table I. show that even at 473° F., a temperature far beyond the range of any ordinary steam boiler, pure water can retain in solution 12.6 grains of sulphate of lime per gallon. The solubility of sulphate of lime in natural water is influenced by the presence of other substances with which it is associated. Thus it is increased by the presence of common salt; but the amount dissolved by the salt water diminishes as the temperature is raised. At 437° F., however, a solution containing 21 parts of common salt to 100 of water can still retain in solution 0.178 part of sulphate of lime, or 124.6 grains per gallon.[‡] In saturated brine Lewes states that sulphate of lime is insoluble. Sulphate of soda is said to increase the solubility of sulphate of lime. Chloride of calcium, on the other hand, diminishes it, but does not reduce it to nil until the proportion of 50 chloride of calcium to 100 water is reached. Chloride of magnesium increases the solubility at the ordinary temperature, but at higher temperatures appears to behave similarly to calcium chloride.

This point has been dwelt upon, because there is a certain class of apparatus, sold for preventing scale in steam boilers, which depends for its usefulness upon the supposition that the carbonate and sulphate of lime are rendered insoluble by the mere heating of the feed water; but so far as the sulphate is concerned, Tilden's experiments prove that such apparatus cannot be efficient, especially that kind in which the feed water is passed into the boiler through a tube in the steam space, where the water occupies only a few minutes in its passage through the tube. What happens in a steam boiler, working at, say, 140 lbs. pressure, is probably as follows: The water containing, say, 5 to 10 grains per gallon of sulphate of lime, besides carbonate, first loses its carbonic acid and deposits the carbonate of lime, partly as mud and partly as scale; the water then concentrates by evaporation, until the sulphate of lime reaches the saturation point; and then the sulphate of lime gradually crystallizes out, mainly upon the plates, cementing the carbonate of lime into a hard scale, so long as the evaporation continues. To suppose that by merely heating the water under pressure, without concentration, the sulphate of lime is entirely thrown down, is contrary to the results of Tilden's experiments; and it is doubtful whether even the carbonate of lime is more than partially precipitated under these conditions, unless the water is actually boiled sufficiently to expel the carbonic acid.

As the solubility of the sulphate of lime in water does not depend upon the presence of carbonic acid, this salt is not precipitated when the carbonic acid is removed by the lime treatment. Before sulphate of lime can be removed, it must be decomposed, which can be done by adding sodium carbonate, when the following reaction occurs:

$$\mathrm{Ca\ So_4 + Na_2\ CO_3 = Ca\ CO_3 + Na_2\ SO_4;}$$

The sulphate of lime is decomposed, carbonate of lime is precipitated, and sulphate of soda remains in solution. In this case there is not a diminution but a slight increase in the total solids, 136 parts of sulphate of lime being replaced by 142 parts of sulphate of soda.

In removing the "permanent hardness"—that is, the hardness due to the sulphates and other compounds of lime and magnesia, these compounds are not precipitated unchanged, but are replaced by other salts of a less objectionable and more soluble character, and the dissolved solids are slightly increased. Such softened water, therefore, should not, any more than unsoftened water, be allowed to concentrate indefinitely in steam boilers, but should be regularly blown off and replaced by fresh water from time to time; or the boilers should be completely emptied at regular intervals of not too long duration. If this be done, no trouble will be experienced; but if the water be allowed to concentrate too far, priming may occur, and even scale may be formed.

Chloride and nitrate of calcium, which are sometimes met with in hard water, are very soluble salts, which do not enter into the composition of boiler incrustation. They are decomposed by sodium carbonate similarly to calcium sulphate; the calcium is precipitated as carbonate, and sodium chloride and nitrate remain in solution.

Sulphate, chloride and nitrate of magnesium are also easily soluble salts, which are not constituents of ordinary boiler incrustation. Sulphate of magnesia may nevertheless prove a highly objectionable substance, if allowed to concentrate in the boiler. A soft carbonate of lime incrustation, when boiled with a solution of sulphate of magnesia, is gradually transformed into sulphate of lime and basic carbonate of magnesia, which latter, if the temperature be high enough, changes into hydrate of magnesia, and the two together then form a hard scale like porcelain, thus:

$$\mathrm{Ca\ CO_3 + Mg\ SO_4 + H_2O = \underbrace{Ca\ SO_4 + Mg\ (OH)_2}_{\text{hard scale}} + CO_2.}$$

Chloride and nitrate of magnesium are objectionable, owing to their corrosive character. The hardness caused by either of the above compounds of magnesium can be removed by adding to the water caustic soda, or, what comes to the same thing and is cheaper, lime and carbonate of soda in proper proportions, by which these magnesium compounds are decomposed and the magnesia is precipitated as hydrate. When caustic soda is used, the reaction is

$$\mathrm{Mg\ SO_4 + 2\ Na\ OH = Mg\ (OH)_2 + Na_2\ SO_4,}$$

and when lime and carbonate of soda are used

$$\mathrm{Mg\ SO_4 + Na_2\ CO_3 + Ca\ (OH)_2 = Mg\ (OH)_2 + Ca\ CO_3 + Na_2\ SO_4.}$$

Thus, all hard water can be softened by means of either lime alone or lime and sodium carbonate, in proportions which depend upon the character of the water to be treated; but a water may be so hard as to be unsuitable for softening, owing to the cost of the chemicals required and the excessive proportion of soluble salts remaining.

Carbonating Softened Water.—Hard water is, as a rule, an extremely dilute solution of the substances which it is wished to remove from it; and the changes which occur when it is chemically softened require time for their completion. These changes are both more rapid and more complete if the hard water and reagents are heated together, than if they are mixed when cold; and water which has been softened when cold is liable to deposit a further small quantity of precipitate on heating. At Derby several years ago, during the experimental softening of water for use in some of the stationary boilers in the locomotive works[*], it was found that the softened water which formed no scale in the boilers had quite the opposite effect in the injectors, feed pipes, and valves. The valves began to give trouble by sticking, and an examination proved that the whole interior of the feed apparatus was coated with a soft deposit, which was gradually choking everything. Some of the deposit removed from the interior of one of the copper pipes gave the following results on analysis:

Carbonate of lime	42.58
Carbonate of magnesia	3.33
Hydrate of magnesia	24.87
Silica	11.05
Alumina	3.68
Peroxide of iron	2.23
Water and organic matter	10.79
Metallic copper (from the pipe)	1.47
	100.00

The large amount of magnesia in this deposit, and the fact that carbonate of lime and hydrate of magnesia occur in it in proportions which are chemically equivalent, whilst in the water itself the ratio of magnesia to lime was much less, afforded a clue which was followed up by heating some of the clear softened water in a glass flask to about 200° F. Nothing appeared to separate at first, but on shaking the water around in the flask an exceedingly thin film peeled off the surface of the glass, and broke up into fragments which floated about in the water. These fragments were found to consist of carbonate of lime and magnesia. The cause of the deposit was now apparent. The chemical reaction between the lime and the carbonate of magnesia,

$$MgCO_3 + Ca(OH)_2 = Mg(OH)_2 + CaCO_3,$$

which was not quite complete in the cold, completed itself when the hot water became raised in temperature in the hot pipes, and a slight further precipitation took place. If thrown down in the boilers, this would have amounted to nothing more serious than a little harmless mud; but by its precipitation in the feed pipes the narrow passages were gradually choked up. The experiment was subsequently made of passing a little carbonic acid into some of the clear softened water before heating, and this was found entirely to prevent further precipitation at 200° F. The remedy, therefore, lay in carbonating the softened water; and eventually a coke stove was set up, and the gases from it were led into the softened water in sufficient proportion to convert all the carbonates into bicarbonates, which is easily ascertained by means of phenolphthalein solution. Since then no further troubue has been experienced.

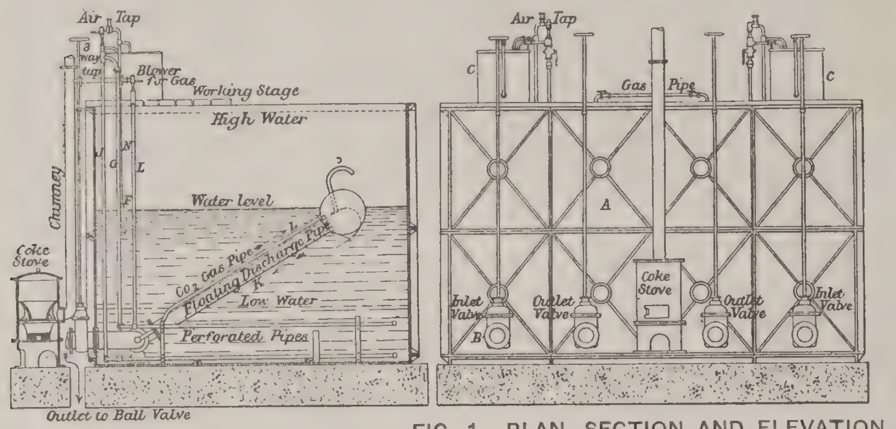

FIG. 1.—PLAN, SECTION AND ELEVATION OF PLANT FOR SOFTENING WATER.

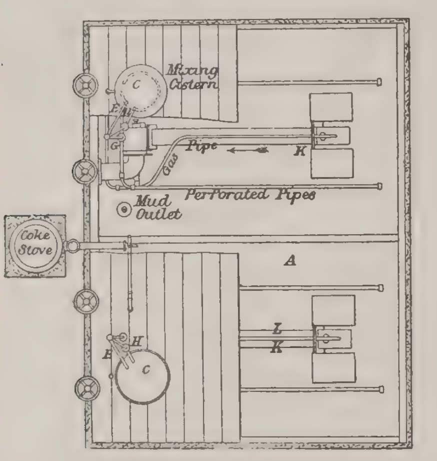

Passing carbonic acid into the clear softened water cannot possibly harden it, as some appear to think. After removal of the carbonate of lime, as much carbonic acid as desired may be put back into the water without hardening it. Carbonating the softened water is, in fact, an advantage, not only when the water is required for feeding boilers, but for some other purposes, such as wool-washing and tanning, because all traces of free caustic alkali and carbonate of soda remaining in the softened water, which would be detrimental, are converted into bicarbonates. By this process softened water is made more palatable for drinking, and the tendency to form a deposit in town mains is lessened, if not entirely obviated.

Softening Apparatus.—The mechanical operations involved in the softening and purification of hard water include the preparation of the reagent, the mixing of it with the hard water, the separation of the precipitate, and the subsequent bicarbonating of the softened water. The apparatus and process employed must be of the simplest possible character compatible with efficiency, and should be applicable to the removal of both temporary and permanent hardness, whether due to lime or to magnesia salts. Nothing could be simpler than the original Clark process of precipitation in plain tanks; but the slow settling of the precipitate necessitated either large and costly tanks or the use of filters; and filtration, besides complicating the process, has been found to be troublesome and expensive when the water contains magnesia, and practically unworkable if any attempt be made to remove the magnesia. In the process about to be described plain tanks are used and filters are dispensed with; for by a special method of manipulation it has been found possible to increase the rate of subsidence of the precipitate to such an extent that about one-eighth of the tank area required in Clark's process is often sufficient. This effect is produced mainly by the simple expedient of stirring up, every time a tankful of water is softened, some of the precipitate which has settled from previous operations. This precipitate by lying at the bottom of the tank becomes aggregated into coarse flakes, which, when stirred up and allowed to settle again, carry down the fine particles of fresh precipitate so rapidly that in from half an hour to an hour, the water clears itself to such an extent that the suspended matter remaining, even at a depth of 6 ft. from the surface, does not exceed about 1 grain per gallon. This very small quantity may for many purposes be neglected; and when perfectly clear water is required the subsequent carbonating redissolves it, hardening the water, it is true, to the extent of one degree or less, according to the amount in suspension, but not sufficiently to be of material importance.

Fig. 1 shows the general arrangement of apparatus suitable for treating on this principle from 5,000 to 10,000 gallons of water per hour. The two exactly similar softening tanks A A, preferably 10½ ft. deep, are intended to be used alternately, one being filled with water which is being softened and clarified, whilst a supply of purified water is being drawn off from the other tank. For 4,000 gallons per hour, or less, one softening tank is sufficient, with a storage tank; for more than 12,000 gallons per hour three tanks are desirable, and for 35,000 gallons and upwards, four tanks. The working capacity of each softening tank is three-fourths of its depth, about 2½ ft. of water and mud being allowed to remain when the water is drawn off, while a margin of 6 ins. at the top is left in filling, which is done by means of the supply pipe B. The quantity of water to be treated being thus exactly known, the proper quantities of quicklime and anhydrous carbonate of soda—58% alkali—are weighed out. The lime is first slacked in hot water in one of the small reagent tanks CC, Figs. 1 and 2, which is filled with water, either from a tap connected with the softened water main, or direct from the softening tank, by means of the tee and pipe between the three-way tap and blower, Fig. 2, by throttling the passage through the three-way tap, turning on steam to the blower, and opening the tap E, Fig. 2; water is then lifted into the tank through the rose F, Fig. 1. The water is boiled by a steam coil, Fig. 2. After the lime has been completely slacked, the alkali is added, and the liquid is boiled for a few minutes and stirred until the alkali is dissolved. The reagent thus prepared is injected into the hard water in the softening tank through the upper row of horizontal perforated pipes, Fig. 1, in the following manner: Steam at not less than 45 lbs.—preferably 90 lbs.—pressure is admitted to the blower, and the three-way tap is turned so that a current of water is established from the softening tank, through the rose F, Fig. 1, the suction pipe N, Figs. 1 and 2, and a three-way tap, down the vertical pipe G, and back into the tank, through the perforations on the upper side of the upper row of horizontal pipes. Into this current of water the reagent solution is slowly admitted by opening the tap H, Fig. 2, and is diffused throughout the volume of hard water in the softening tank. The operation, including the rinsing of the reagent tank, is generally allowed to occupy ten minutes. The suction pipe in the reagent tank extends below the perforated false bottom O, Fig. 2, which prevents any pieces of stone, etc., in the lime from getting into the pipe. The tap H having been shut off, the air-tap over the blower opened, and the three-way tap reversed air is forced down the pipe J, Fig. 1, and through the perforations in the under side of the lower row of pipes, into the mud at the bottom of the tank, stirring up a portion of the mud and diffusing it through the water. After the blower has been in operation for a few minutes—usually ten, but varying with different waters—the steam is shut off, and in about an hour or less the water will be ready to be drawn off. The operations of carbonating and drawing off are effected simultaneously by means of a floating discharge pipe K, Figs. 1 and 3, the body of which is of brazed copper, rectangular in section, having at intervals along the bottom, baffles, which cause the water to flow down in a cascade and splash up into the gases, which are injected from the coke stove into the cast-iron head of the pipe through the gas pipe L. The water and surplus gas escape together, at the lower end, through a ball valve, the carbonated water falling into the cistern from which it is drawn for use, and the gas escaping into the air. The coke stove, Fig. 1, contains a supply of coke in the upper part, which, by falling through the cone, maintains a fire of constant thickness about 12 ins. in depth over the firebars. The top of the chimney, Fig. 1, is closed by a butterfly valve, below which the gas is drawn off through a branch for carbonating. In order to ensure a constant and ample supply of gas, a small blower is fixed in the branch pipe. When the ball valve closes and water ceases to flow down the discharge pipe the gas accumulating in the head of the pipe forces the water below the sill M, and escapes through the pipe N, without disturbing the water in the tank. When the ball valve opens again the floating pipe first empties itself of water, and the gas then escapes through the ball valve, relieving the pressure, and allowing water again to pass over the sill and down the pipe with the gas, so long as the valve remains open.

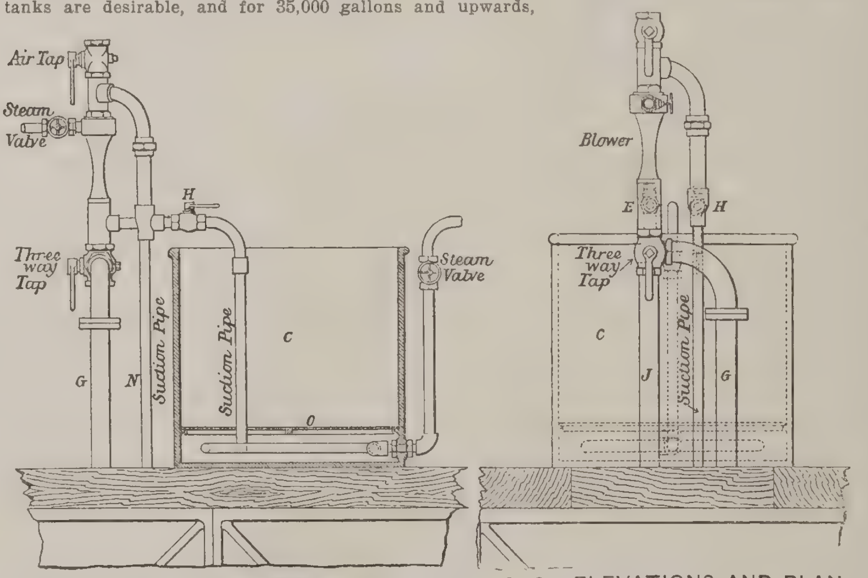

FIG. 2.—ELEVATIONS AND PLAN OF REAGENT TANK, BLOWER AND CONNECTIONS.

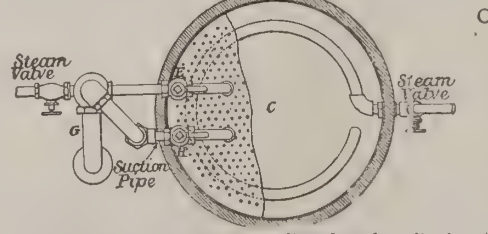

The precipitate is prevented from unduly accumulating in the tanks by its partial removal at regular intervals; this is effected in various ways to suit different circumstances. From the nature of the precipitate, and the fact that it is not allowed to consolidate, it is easily dealt with. In a small apparatus a mud pipe leading to a drain is provided near one corner of the tank; and by lifting a plug, and using the blower to stir the mud, a sufficient quantity can be run off. In a larger apparatus it is swept out into a pipe or trough, which conveys it into shallow draining pits, whence it can be carted away; or, it is raised from the tank or trough by a steam lifter, and discharged direct into a cart or wagon lined with waste furnace ashes, through which the excess of water soon drains, leaving the nearly dry mud and ashes ready for tipping.

General Remarks.—The softening of water is an exact process, and in order to obtain satisfactory results proper attention must be given to it. Rough-and-ready methods may succeed in a few instances, but they will not answer in the long run for general adoption. Automatic machines for softening water, which are said to require attention only once or twice a day, and which run continuously, are not to be recommended. In the comparatively rare cases where lime alone is required, and the hard water is practically invariable in character, the continuous method of mixing the hard water with lime water in properly proportioned streams may give good results, provided the machine for preparing the lime water is thoroughly efficient and properly attended to. Lime water is a saturated reagent;

it can be prepared of nearly constant strength by causing water to flow continuously through a mass of it kept in agitation, and the solution being very dilute, does not need extremely fine measurement. But when the same plan is adopted with a solution of caustic soda of much greater strength, finer measurement is necessary; and unless it be carefully looked after, a deficiency or an excess of reagent in the softened water may easily occur. Another objection to the continuous flow system of softening is that, unless frequent tests are made, a large quantity of improperly treated water may pass from the apparatus. Therefore, it is preferable to soften a known volume of water with a known weight of chemicals, and to test each tankful; the excess or deficiency of reagent can then never be serious, even with a variable water. With the tanks fitted as above described, the manipulation of 20,000 or 30,000 gallons of water is as easy as that of one gallon; the appliance for mixing is effective and easily kept in order; every tankful of water may be treated with whatever weight and kind of chemicals are desired, and every drop of water gets its proportion. The labor is light. No expensive buildings are required; all that are necessary are a storehouse for lime and coke, and a covered working stage over the tanks; and the apparatus generally is almost indestructible, necessary repairs being limited to keeping the valves in order, occasionally cleaning out the holes in the perforated pipes, and painting the tanks outside; experience shows that they do not rust inside.

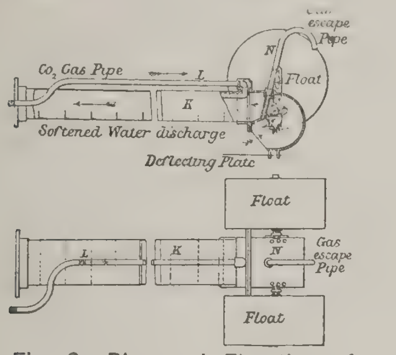

Fig. 3.—Plan and Elevation of Floating Discharge Pipe.

This process has been in operation since January, 1892, in the Midland Railway Works, at Derby, clarifying and softening the sewage-polluted water of the river Derwent; reducing the hardness from about 15° to 4½° to 5°, and effecting considerable organic purification, at an inclusive cost for chemicals, labor and interest on outlay, of about 2 cts. per thousand gallons. The water is of variable character. The following analyses recently made show the composition of the water before and after softening:

	Grains per gallon	
	Unsoftened water.	Softened water.
Carbonate of lime	9.90	2.63
Carbonate of magnesia	0.78	....
Sulphate of lime	3.06	0.17
Sulphate of magnesia	2.89	1.67
Sulphate of soda	0.41	5.10
Common salt	2.56	2.64
Nitrate of soda	0.28	0.28
Silica	0.34	0.34
Water not expelled at 266° F., organic matter, etc.	1.78	1.37
Total	22.00	14.20
Degrees of hardness	15.4	4.14

By using more lime and alkali, the hardness can be reduced to 3°; but as the softened water is used in locomotives, it is found desirable not to reduce it so low.

The organic purification effected is shown by the following figures:

	Water,	
	From pump main as delivered into tanks.	Same after treatment; 30 minutes' subsidence.
Free ammonia (parts per million).	1.15	1.08
Albuminoid ammonia*	0.42	0.28
Oxygen absorbed in 4 hrs. at 80°F.†	0.204	0.106

*Parts per million. †Grains per gallon.

Bacterial Purification.—Of greater importance from a sanitary point of view is the remarkable bacterial purification effected by this process, which the polluted character of the unpurified river Derwent water brings into special prominence. Before treatment the water swarms with a bacteria capable of growing on a gelatine plate; after treatment, few are left in the water. Dr. Percy Frankland showed, several years ago, that the precipitate of carbonate of lime produced in Clark's process carries down about 98% of the organisms contained in the water; the author's own experiments show that the repeated stirring up of the old precipitate does not impair the efficiency of the purification in this respect, even when the mud is swarming with bacteria, as that in the tanks at Derby must be.

Other Applications.—During the last five years this process has been adopted for softening water at upwards of 50 works at home and abroad, including water-works, dye and bleach works, woolen and worsted mills, paper mills, laundries, etc., where the quantities of water treated by it range from 500 to 45,000 gallons per hour. It has been found to be applicable to all kinds of hard water, and gives the best results when magnesia is present, the hydrate of magnesia forming a coarser precipitate which settles more rapidly than pure carbonate of lime.

An interesting example of the application of this process to a public water supply is afforded at the new waterworks of Swadlincote and Ashby. The water, which is pumped from a well, besides being very hard, contains in solution a considerable amount of iron, which precipitates on exposure of the water to light and air. This iron is successfully and completely removed, the hardness of the water is reduced from 22° to 23° to an average of 8½°, and the softened water is bicarbonated, at a total inclusive cost—for chemicals, labor, steam for the blower, coke for carbonating, and interest at 6% on capital and outlay—of 1.6 cts. per 1,000 gallons. Here 2% is allowed for depreciation and 1% for repairs, which is considered ample for such a plant. Lime only is used in softening this water. The presence of the iron, instead of being a trouble, is a positive advantage in the purifying process, as it assists the precipitation, which is remarkably rapid. The tanks are 10½ ft. deep; and 40 minutes after shutting off steam from the blower the water is clear, almost to the bottom of the tank, and ready to be drawn off. The guaranteed output of the plant is 45,000 gallons per hour, or 540,000 gallons per day of 12 hours; this quantity of water is easily softened and purified in four tanks, each having a working capacity of 27,000 gallons. The purified water gives complete satisfaction to the whole of the consumers, and is being largely laid on to works of various manufacturers in the district.

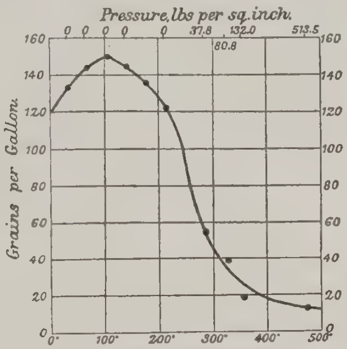

Fig. 4.—Diagram Showing Solubility of Calcium Sulphate in Water at Various Temperatures.

General statements as to the cost of softening water by any particular process must be misleading, because so much depends upon the quantity as well as the character of the water treated. A water of which the hardness is entirely "temporary," that is due to carbonate of lime and carbonate of magnesia, can be softened with lime alone, which costs, per ton, say, £1 or less; but "permanent" hardness, due to sulphate of lime, can be removed only by using alkali, costing at present prices nearly £5 per ton. Less than one pound of lime per thousand gallons of water will remove 10° of temporary hardness; but 1.6 lb. of alkali is required for the removal of 10° of permanent hardness due to sulphate of lime, while sulphate of magnesia is still more expensive to remove. Taking quicklime at £1 per ton, and alkali at £5 per ton, the cost of the chemicals required for softening water is about as follows per thousand gallons:

For every 10° of temporary hardness...........0.22 ct.
" " " permanent " ....1.90 cts.

Thus permanent hardness is approximately nine times as expensive to remove as temporary hardness. These figures for the cost of chemicals are quite independent of the particular mechanical process employed, except that caustic soda, which is used in some water softeners, increases the cost. Clark's process is never used for any other purpose than the removal of temporary hardness, and this is why the cost of softening by that process is low. Assuming the cost of labor, interest on outlay, and other incidental expenses to amount to 1 ct. per 1,000 gallons, the cost of softening water of 20° hardness would vary as follows, according to the nature of hardness:

	Cost per 1,000 gallons, ct.		
Nature of hardness.	Chemicals.	Labor, interest, etc.	Total.
All temporary	0.44	1.0	1.44
Half temporary, half permanent.	2.12	1.0	3.12
All permanent	3.80	1.0	4.80

Advantages of Softening.—The chief advantage of softening hard water for boilers, apart from the saving of fuel, are increased safety of working, longer life of the boilers, and a great saving in the cost of cleaning and repairs. It has also been found that in a battery of boilers the cost of an extra boiler may be saved, owing to the smaller amount of repairs and to the saving of time required for cleaning. There is no doubt that, to avoid incurring the cost of a softening apparatus, much more money is frequently spent in "boiler compositions" than would pay for properly softening the water. Many of these nostrums are useless, and some dangerous, whilst the best are only a partial remedy for the evils complained of.

Pitting and corrosion of boilers cannot be caused by properly softened water, unless it be allowed to concentrate unduly; neither can the use of such water cause leakage. Corrosion of brass cocks and gage fittings most likely arises from the use of alkali in excess, which is simply due to neglect. Pitting of boilers, even where apparently caused by softened water, may really be due to the uncovering of old "pits" by the removal of scale, which always occurs when softened water is first used in a dirty boiler. Pitting when once started is likely to continue, owing to galvanic action between the metal and the crust of oxide of iron contained in the cavity. By thoroughly scraping the pits so as to remove every trace of this oxide, and by then painting the dry metal surface with a thin coating of mineral lubricating oil, Mr. Deeley has found pitting to cease in many instances when the water was kept slightly alkaline. Leakage of the boiler plates sometimes occurs soon after commencing to use softened water in an old boiler, and is sometimes wrongly attributed to the water; it is really due to the loosening of the old scale, which had covered up defective places.

The softening of water is a necessity in all cases where soap has to be used, as in the washing, milling and scouring of textile fabrics. For such work a great saving may be effected by a properly constructed softening apparatus, without which the softening must be expensively done with soap or soda. The advantage may be judged from the fact that 1,000 gallons of water of only 10° hardness will destroy 12 lbs. of the best hard soap, costing, say, 50 cts.; the same quantity of water can be softened by 1 lb. of lime costing about ⅕ ct., or by 1.6 lb. of alkali, costing rather less than 2 cts., and the soap is saved. One firm state that they save 40% of soap and 25% of alkali by using their own well-water softened from 12° to 3°, instead of using town water of 7° hardness. Several firms testify to the saving of soap in wool washing, and to the improved results obtained by the use of softened water for dyeing, especially where the dyes are applied in neutral or slightly alkaline baths. The material is less liable to fleck, the formation of objectionable lime lakes with the alizarine dyes is avoided, and the colors obtained are more brilliant than when hard water is used. It should not be forgotten that, in any laundry where hard water is used, all the water must be softened in the wash-tub before a lather can be obtained; and this is done at the cost of soap and soda wastefully used, and with all the objectionable lime and magnesia soap scum left in the water.

Clarification of Waste Water.—This process is not limited to the softening of hard water, but has proved very effectual in the clarification of manufacturers' waste water. During the last three or four years apparatus has been supplied for this purpose to about 25 works of various kinds, including bleach and dyeworks, calico-printing works, paper mills, cloth mills, etc., and gives great satisfaction. No novelty of chemical treatment is adopted, but it is found that the thorough method of mixing leads to a great economy of chemicals; and owing to the rapidity of precipitation there is also considerable economy in the amount of tank capacity required. Lime and aluminoferric are the chemicals chiefly used. The clarification of the water is perfect, and when desired the alkalinity of the effluent is neutralized by carbonating. The water is also decolorized.

A TIN-PLATE TRUST was incorporated on Dec. 15 at Trenton, N. J., under the name of the American Tin-Plate Co., with an authorized capital of $50,000,000. The stock is divided into $30,000,000 of common and $20,000,000 of preferred, the latter to pay 7% cumulative dividends.

◆

RULES FOR WORKING IN COMPRESSED AIR were presented to the late International Congress on Internal Navigation by three Austrian doctors, Messrs. Heller, Mager and von Schroetter; they are given as follows in "Le Genie Civil:" They recommend that no work of this character be done under pressures exceeding five atmospheres, or say 75 lbs. per sq. in. The workmen employed should be between 20 and 50 years of age, and should only be acepted after a medical examination into the state of their heart, lungs, vascular system and ears. There should also be medical supervision during the performance of the work. The compressed air should be admitted very gradually; for novices the pressure should not be increased faster than one-tenth of an atmosphere per minute; for trained workmen this rate can be increased to 10 minutes for 1½ atmospheres, 15 minutes for 2½ atmospheres, and 40 minutes for 5 atmospheres. If the renewal of air is well assured during lockage, the capacity of the lock may be 720 liters per man, or, say, 3 to 4 cu. m. for four men. As to the time spent in the working chamber, there is no necessity for limiting it, provided that the pressure is not excessive. It is well to lodge the men near the work and to build special rooms for them at the head of the shaft. The workmen should always dress in woolens to avoid chills.

A FILTER FOR REMOVING OIL FROM FEED-WATER.

A very essential part of the equipment of a surface-condensing steam engine plant, especially in marine service, where fresh feed water is not readily available, is some means of removing from the water of condensation, which is to be used over again as feed water, the lubricating oil which has been carried out of the cylinders by the exhaust steam. In surface-condensing the same water is used over and over again, but the oil, being fed to the cylinders continuously, gradually accumulates in the feed water, and enters the boiler, where it may become a source of danger. A thin film of oil on the heating surface preventing the water from adhering to it, may cause a plate or a tube to be overheated, and possibly cracked, and this danger is greater if the oil makes a thick paste with any mud or fine scale that may happen to be present in the boiler.

The apparatus for removing oil from feed water, shown in the accompanying illustrations, was put on the market a few years ago in England by Messrs. Railton & Campbell, and largely introduced by them in ocean-going steamers. It is now being made in this country by the Ross Valve Co., of Troy, N. Y. The filter is placed between the feed pumps and the boiler. It consists essentially of a chamber containing a bag made of the fabric known as "Turkish toweling," so folded as to obtain a large area of filtering surface in a small space. The surface of the bag is formed into a series of deep circular corrugations by being drawn over the bronze skeleton shown at the left of the perspective view, and drawn down between each of the sections by means of strings wound around it. The area of the filtering surface is made from 250 to 1,000 times the area of the feed pipe, according to the service required. The threads of the Turkish toweling retain the oil until they become saturated with it, while they let the water pass through. The filter is so constructed that the water passes from the outer side of the bag through it and the metal skeleton to the interior of the latter, and thence to the outflow pipe, as shown in the sectional view. The oil gradually clogs up the filtering material, increasing the resistance to the passage of the water. This resistance is indicated by the difference in the readings of the two pressure gages, one on the inlet and one on the outlet side of the filter. When the difference in pressure reaches 2 or 3 lbs. per sq. in. the filter may be cleaned by reversing the direction of the current, allowing the wash water to run to waste, or by changing the filter bag, a fresh one always being kept in reserve. The head of the filter chamber may be opened, the filter bags changed, the skeleton and the bag being removed and replaced by means of the long handle seen in the half-tone cut, and the head replaced inside of five minutes. The washing of the filter by reversing the current of water is done by operating the valves shown in the sectional view in the following manner: The inlet valve, A, is first screwed down and closed; B is then closed, and the drain cock opened. Valve A is then opened a little and the current of water thus created washes the outside of the filter. A is then closed and B opened, causing water to pass from the boiler through the filter-bag from the inside. The valve, A, is ingeniously made to perform the double function of a stop-valve and a by-pass valve, as may be seen in the sectional view.

We are informed that these filters are in use on most of the transatlantic steamers of the White Star and North German Lloyd lines, and that many of these vessels make a round trip without changing the filter cloth, merely washing it by reversing the flow, as before explained, as often as it clogs. The manufacturers are also finding considerable demand for these filters for use in steam power stations, and they are even sending them as far away as South Africa.

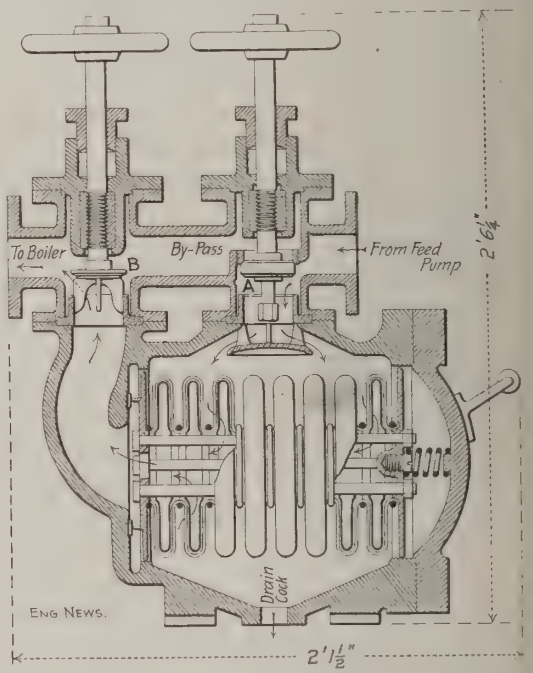

Fig. 2.—Sectional View of Ross Feed-Water Filter.

THE FAILURE OF A LARGE GAS HOLDER IN NEW YORK CITY.

In our last issue was given a brief description of the failure, on Dec. 13, of an immense gas tank, or holder, while undergoing a contractor's test previous to being accepted by the Consolidated Gas Co., for whom it was being constructed by the Logan Iron Works, of Greenpoint, Brooklyn, N. Y.

With this issue we present two views of the wreck, affording a fair idea of the complete destruction of the tank. Fig. 1 is a view of the eastern half of the wreck, and shows the mass of plates, girders and braces so badly tangled and twisted that, although a large force of men was at once put to work to clear away the wreck, very little impression has been made even at this time.

The holder, according to the best obtainable data, was a 4-section telescoping tank, 174 ft. in diameter and 160 ft. high, when fully extended, with a retaining or sealing tank 178 ft. in diameter and 42 ft. deep, 17 ft. of which was above ground, as seen in Figs. 1 and 2, and 25 ft. below. For the benefit of those not conversant with gas holder design, we may explain that the retaining tank is simply a huge reservoir filled with water. The gas-containing tank is like a great inverted tumbler, its lower edge immersed in the water of the tank, and is moved up or down as the gas is pumped in or drawn out. The gas-containing tank is subject, of course, to only a trifling pressure; but the tank which contains the water has to sustain hydrostatic pressure the same as any water reservoir or stand-pipe.

This great retaining tank, holding, when filled with water, some 1,044,621 cu. ft., burst through some cause not as yet determined, and all the water above the ground level instantly rushed out. Its volume was so great that buildings were wrecked by it, and it rushed through the streets with such force and volume that passers-by were carried for blocks in the flood as by a river. The total of deaths and fatal injuries due to this flood now numbers eight. Of course, the failure of the retaining tank brought down the entire overhead structure; and the thin plates of the gas-containing tank were bent and torn in all sorts of shapes by the force of the water and the collapse of the heavy overhead columns and girders.

The retaining tank, whose failure appears to have been the original cause of the disaster, was built up of plates varying in thickness from 7-16 in. at the top to 1¼ ins. at the bottom. The manner in which these plates were torn is admirably shown in our illustrations. It will be seen that the fracture went through the body of the plate and showed no tendency to follow the riveted seams. In Fig. 2 several 4-ft. plates are seen torn nearly straight across, the fracture, however, in some cases taking a curved form similar to that seen in the fracture of a pane of glass. There were several similar tears at various other points on the portion of the tank still standing.

An examination of these fractures shows metal of a rather coarse crystalline structure at the center of the plate, shading off into a very fine grain at the surface, with here and there splinter edges much like broken case-hardened material. In one case two straight cracks appear running directly across the short dimension of a plate, in the unharmed standing portion. Of course, these fractures in these plates are not conclusive evidence that the metal from which they were rolled was too hard, or defective in other particulars. But they are certainly significant enough to call for a searching investigation into the specifications for these plates, their chemical composition, and their behavior under test. Our endeavors to obtain this information for the benefit of our readers have so far been unsuccessful; but it is certainly to be hoped that it may be brought forward in the Coroner's investigation which is to be made.

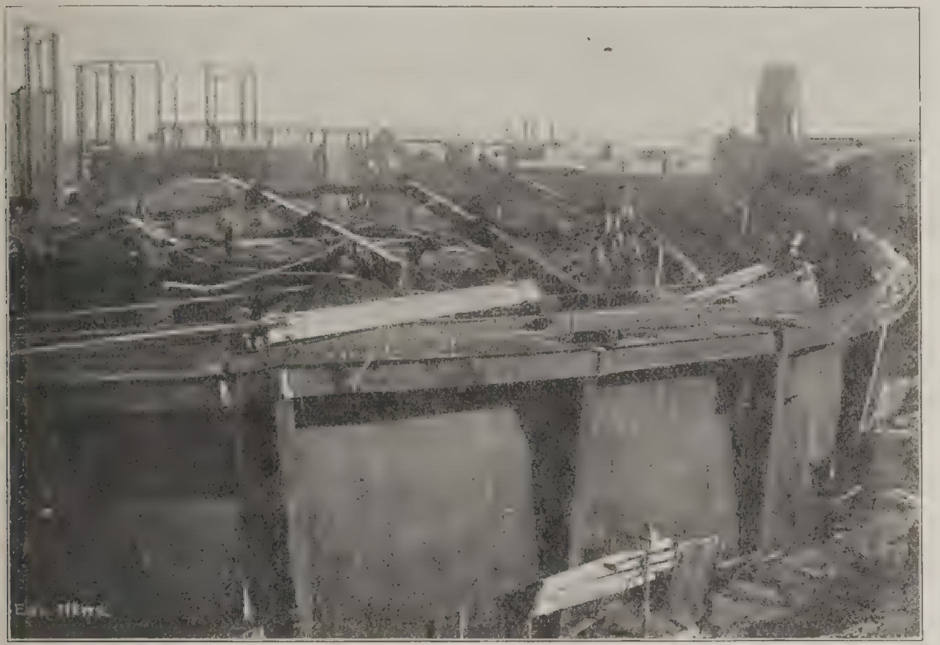

FIG. 1.—WRECK OF A LARGE GAS HOLDER; CONSOLIDATED GAS CO., NEW YORK CITY.

(From a photograph looking in the direction of the point of failure and showing the above-ground portion of the water tank.)

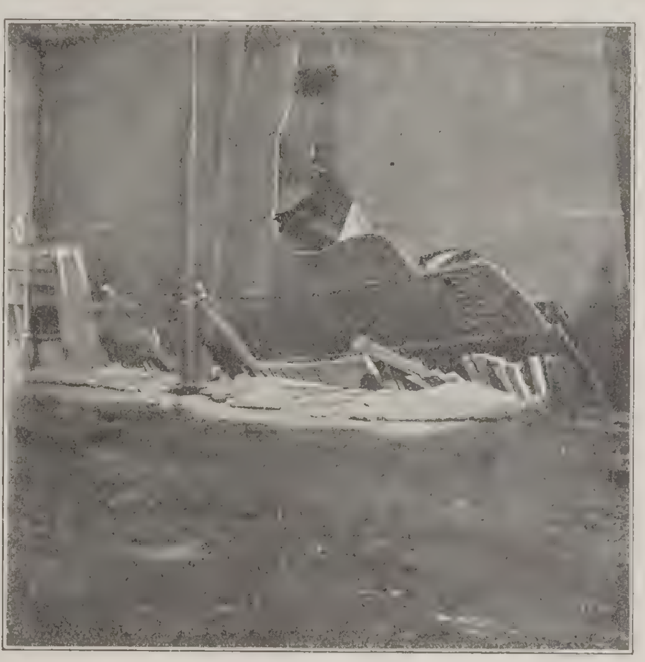

FIG. 2.—ONE OF THE TEARS IN THE STANDING PORTION OF THE WATER TANK.

(The fractured plates vary from ⅝-in. to about ⅞-in. in thickness.)

One feature in the design of the structure is made apparent in our photographs, and we are sure will be examined with interest by our readers. We refer to the support of the entire overhead structure on box-brackets bolted to the upper and thin portion of the retaining tank. These brackets, as may be seen in both figures, extend from the top of the retaining tank down to about the ground level. The question what stresses were set up in the plates of the tank by these brackets and the weight which they supported is one worth consideration. It may be, of course, that this method of support was a usual and proper one; but no reason is apparent why the overhead structure might not have been as well supported by independent piers of masonry, thus avoiding any possibility of distortion of the huge water-tank.

◆

A MASONRY-PIER MOVED BY ICE was successfully put back into place on the St. Lawrence & Adirondack Ry. at the bridge over the Chateauguay River, in Quebec. The method adopted is described in a paper read by Mr. R. W. Leonard before the Canadian Society of Civil Engineers. The water was from 8 to 12 ft. deep, and the piers were built in a box-caisson sunk upon 75 piles, and finally riprapped. The ice-field which broke loose and caused the damage, was about 3 ft. thick, and the pier was shoved out of position at one end about 1 ft. Mr. Leonard then sunk a crib, 20 x 13 ft., alongside the pier; loaded this crib with stone and drove a line of nine piles on the outside of the crib. Four 50-ton. hydraulic jacks were then placed between the crib and the pier, and the latter was successfully pushed bask into place without a crack in the masonry. The pier, with its platform, weighed in all about 500 tons; the total cost of putting the pier back into its proper position was about $800.

◆

A PAN-AMERICAN EXPOSITION, at Buffalo, N. Y., is planned for 1901, and the Mayor of that city has appointed a provisional committee to take decisive action in the matter. The City of Detroit is discussing a similar exposition.

◆

A GREATER AMERICAN EXPOSITION in Omaha, in 1899, is proposed by the citizens of Omaha, and $105,000 was subscribed at a meeting Dec. 16. This sum is sufficient to secure the grounds and buildings of the recent Trans-Mississippi Exposition. A committee, with Mr. Edward Rosewater as chairman, has been appointed to prepare articles of incorporation for the enterprise.

◆

THE HOUSE BILL FOR AIDING THE PHILADELphia Commercial Museum, by a grant of $350,000 to assist in providing permanent buildings, etc., passed by a vote of 142 to 70, under suspension of the rules. This permanent exposition, on which over half a million has already been expended, is intended wholly to promote the export trade of the United States. Its purpose is to show the products of all parts of the world; to educate manufacturers as to the articles most needed in foreign countries; to instruct merchants in packing and shipping goods, and in every way possible to aid in the development of foreign trade. The Councils of Philadelphia have contributed 56 acres of valuable ground within ten minutes ride of the City Hall; and the government appropriation is not available until Pennsylvania appropriates $300,000 more. The City of Philadelphia has already contributed $200,000 towards the buildings, and the State of Pennsylvania has voted $50,000, so that only $50,000 more must be raised. The plans for the buildings call for four acres of floor space, and numerous applications for this space have been received from manufacturers and merchants and dealers in the United States, Mexico, Central and South America, Africa, Australasia, India, Japan and Europe. Mr. William P. Wilson is the Director of the Museums.

◆

THE EXPORTS OF THE UNITED STATES for 1898, in domestic merchandise, will amount to over $1,200,000,000 in value, as compared with less than $1,140,000,000 for the United Kingdom. Eight years ago, England shipped goods valued at $1,280,758,643—the greatest world's record, while that from the United States for the same year was worth $845,999,603. The November exports from the United States, says the Bureau of Statistics, broke the record with $127,483,467, exceeding that of November, 1897, by over $13,000,000, and by over $42,000,000 that of November, 1895. Including a few exports of foreign products, the total for November, 1898, was nearly $130,000,000, while the imports were only $52,109,560 in value.

◆

TWENTY AMERICAN FREIGHT LOCOMOTIVES have been ordered for the Midland Railway Co., of England. The Schenectady Locomotive Works have the contract for ten of these and the Baldwin Locomotive Works are said to have the other ten. Within the last week the latter firm has closed contracts for 56 locomotives, 16 of which are for the Imperial Railways of China. The Schenectady Works are now shipping 27 locomotives constructed for the Nippoo Railway of Japan; and they are also completing 14 heavy compound consolidated locomotives for the Northern Pacific Ry. The Reading Railway Co. has made a contract with the Baldwin works for 25 freight engines and five heavy switching engines, especially designed for use on the Reading Subway, in Philadelphia, and on parts of the main line. The Baldwin works are also building ten large freight engines for the Chicago & Western Railroad Co. These contracts, coupled with numerous smaller orders, requires day and night work and a force of over 5,000 men in the Baldwin shops. The "Pall Mall Gazette" explains the English order as a consequence of the engineering strike in England. British locomotive builders are said to be only able to handle arrears of work and can take no new orders.

◆

EXTRAORDINARY ACTIVITY IN THE IRON TRADE is reported from all the leading districts. The tonnage of the blast furnaces in operation on Dec. 1, according to the "Iron Age's" statistics was 235,528 gross tons per week, the highest figure ever recorded. Stocks of pig iron at the furnaces are reduced to 544,024 tons, as compared with 805,311 tons on July 1. Sales of pig iron and of steel in various shapes aggregating about 200,000 tons, were reported in one week at Pittsburg and Chicago. Prices of Bessemer pig iron have advanced 25 cents per ton. Fears are expressed that there will be a sudden scarcity of pig iron in the market, and that the conditions of the "boom" of 1879 and its disastrous consequences may be repeated. If a marked advance in prices should take place it will seriously curtail the export trade unless European prices are likewise advanced.

◆

THE TWO RUSSIAN WARSHIPS now being built by the Cramps of Philadelphia, will have the following dimensions: The protected cruiser "Bear" will be 400 ft. long, 52 ft. beam, 6,500 tons displacement, 20,000 I. HP.; contract speed for 12 continuous hours, 22 knots; coal-bunker capacity, 1,400 tons. She will have a main battery of 12 6-in. rapid-fires, with 12 3-in. rapid-fires, and 6 47-mm. rapid-fires. There will be four torpedo tubes, with two of them under water. All the guns will be guarded by shields. The battleship will be 376 ft. long, 72 ft. beam, maximum draft 26 ft., 12,700 tons displacement, 16,000 I. HP., speed for 12 hours 18 knots, bunker capacity 2,000 tons. The side armor will be 7½ ft. deep and from 2 ins. to 9 ins. thick; above this will be 6-in. armor for the gun deck with 9-in. cross bulkheads. She will be armed with 12-in. guns in 10-in. barbettes and turrets, and with 6-in. and 3-in. rapid-fire guns, and six torpedo tubes. The full descriptions of these two ships are not yet published, but they are evidently to have great speed and an efficient rapid-fire batteries, with a minimum of armor.

◆

PROPOSALS FOR RAISING THE "MAINE" and "Cristobal Colon" will soon be asked for by the Secretary of the Navy, as a result of the many offers received by the Navy Department from responsible firms, who are willing to undertake the work at their own risk.

◆

THE HAVANA FLOATING DRY-DOCK, having a lifting capacity of 10,000 tons, is held to be floating and movable property by the American Evacuation Commission, and will be sold for the account of the Spanish government. This dock was built in England at a cost of $600,000; but is said to have been so badly used by the Spanish engineers that it is now not worth half that sum.

◆

THE INFLUENCE OF COAL IN NAVAL WARFARE is indicated in the late report of the Bureau of Equipment of the U. S. Navy Department. During the fiscal year the sum of $2,122,005 was paid for 452,551 tons of coal, or at the rate of $4.68 per ton, as compared with 138,318 tons, bought for the navy in the previous year of peace. Of the first amount 74,111 tons were purchased abroad at an average rate of $8.12 per ton, as compared with 56,268 tons, at $6.68 per ton, bought abroad in the previous year. At Key West, with an original coal-shed capacity of only 3,000 tons—later raised to 9,000 tons—warships were often present having a bunker capacity of from 10,000 to 12,000 tons. The government first met the demand for colliers by the purchase of five vessels having an aggregate carrying capacity of about 13,000 tons; and by purchasing other foreign ships, the Bureau eventually had in Atlantic waters an efficient, armed collier fleet capable of carrying 50,000 tons of coal. At one time, at Hampton Roads, there were afloat on steam colliers, 40,000 tons of the best American coal, ready to be sent at an hour's notice to any point desired. Another experience of the war demonstrated the absolute necessity of providing either tank ships or distilling ships of large capacity for furnishing fresh water for boiler use. The distilling apparatus on our warships, with the notable exception of the "Oregon," was inadequate to keep up the supply of fresh water needed, and the boilers on blockading ships suffered from the want of fresh water. The Bureau believes that tank ships, such as are used for carrying oil in bulk, will be most useful in transporting water to a fleet. The purchase of fresh water for steaming purposes, under former methods, is now too expensive. For example, at Hampton Roads, 1,000 gallons of fresh water delivered to the ships costs $7.50; the same amount drawn from the mains at the Norfolk Navy Yard into a water-barge and towed to the ship, costs 30 cts. During the war, $2,067.50 was paid for 432,000 gallons of fresh water delivered to the "St Paul," at Tompkinsville, N. Y.; had this water been taken at the Brooklyn Navy Yard and towed in a barge to the ship, the cost would have been $43.25.

◆

A UNIFORM .30 caliber, for small arms and machine guns, is recommended by the board of Army, Navy and Marine officers now in session in New York, with Col. Alfred Mordecai, U. S. A., presiding. The board proposes this caliber for all branches of the service, because the army is already armed with a number of such guns and large quantities are being daily turned out to meet the possible demand of an increased army. The cannelured cartridge-case is considered most suitable for use with these small arms and machine guns; provided, the change can be readily made in the army guns now in use.

◆

THE 8-IN. CAST-STEEL, ONE-PIECE GUN, invented by Dr. R. J. Gatling, was submitted to the first of its series of tests at Sandy Hook on Dec. 15. Five rounds were fired with brown prismatic cocoa powder, in charges of 68, 132, 135, 141 and 142 lbs., and a projectile weighing 300 lbs. The gun successfully withstood these tests, though the highest chamber pressure recorded was about 37,000 lbs. per sq. in. This gun is cast, muzzle down, from a combination of steel and nickel, showing a tensile strength of 50 tons to the sq. in. To insure against blowholes a sinking head of 15 tons of metal is used in pouring. When bored the steel is found to be of fine quality, and homogeneous; but the chief claim of Dr. Gatling lies in his method of reheating the ingot and then cooling from the interior in such manner as to practically provide a series of shrunked bands about the bore. The full test includes 300 rounds, and the cast-steel gun must prove its equal efficiency with built-up and wire-wound guns before it will be recommended by the board having its test in charge. In 8-in. built-up guns an abnormal chamber-pressure of 100,000 lbs. has been recorded; and the Brown 5-in. wire-wound gun has often withstood pressure of 50,000 lbs., and one of 82,850 lbs.

◆

THE LEAGUE OF ASSOCIATED ENGINEERS, with headquarters at the House of the Engineers' Club, in New York city, aims to bring closer together American engineers in civil life and those serving under the government in the engineering profession. It is also intended to foster a more active public interest in the engineering aspect of our national defense and to assist government engineers in their efforts to secure the highest possible efficiency both in material and in personnel. Technical education and training of a high order in these branches of the service are imperatively necessary; and in encouraging the necessary legislative measures the citizen engineer performs a patriotic duty and betters the standing of the profession generally. At the present time the Executive Committee of the League is engaged with H. R. bill No. 10,403, entitled "A bill to reorganize and increase the efficiency of the personnel of the Navy and Marine Corps of the United States." The League intends to press the passage of this bill, and any who have suggestions to make, or who can assist in this work, are asked to communicate with Mr. Stephen W. Baldwin, Chairman, care of The Engineers' Club, No. 374 5th Ave., New York.

◆

THE PROPOSED DEEPENING OF THE CHANNEL at the entrance of New York Harbor is being examined by a special board of engineer officers, made up of Col. Henry M. Roberts, Lt.-Col. C. W. Raymond and Major H. M. Adams. The surveys and plans recommended by Col. Ludlow are being especially considered. These, as the best of three alternative routes, practically cover the deepening of the direct East channel to 35 ft., thus avoiding the long detour by the Gedney and Main channels, and saving several miles in entering the harbor.

◆

A 30-FT. CHANNEL IN THE DELAWARE RIVER, 600 ft. wide, is again agitated by maritime interests in Philadelphia. The length of this channel would be about 56 miles and it would require the removal of 32,375,000 cu. yds. of mud, etc., and about 12,100 cu. yds. of rock. The estimated total cost would be $5,935,000, and the work could be finished in five years. The present channel is 26 ft. deep, but this is inadequate for the demands of commerce.

◆

THE BALTIC-BLACK SEA SHIP CANAL, so often reported as a possible enterprise, will not be built, according to a communication from the Russian government to U. S. Consul-General Halloway, of St. Petersburg.

◆

WATER POWER IN PORTO RICO is abundant and efficient, according to Gen. Roy Stone. The numerous small rivers have an average fall of 2,500 ft. in passing from the central mountainous country to the coast; and on these streams are many high water falls.

◆

THE RAILWAY SYSTEM OF THE BERNESE OBERland, starting from Interlaken, Switzerland, has a total extent of a little over 42 miles, including the 7.8 miles of the Jungfrau railway now under construction, described in our issue of Dec. 15. From Interlaken to Zweilutschinen, 5 miles, ordinary locomotives are used; but beyond this point the system of traction is a mixed one, including both ordinary and rack rail lines. The maximum grade surmounted on the lines to Lauterbrunnen and to the Grindelwald is 12%; but the lines to Schynigeplatte and to the Wengeralp have rack rails for the whole length, and the maximum grade is 25%. The line to Murren is operated by a counterpoised cable, over a length of 4,526 ft., with an incline of 26%. These lines have a gage of 2.62 ft., and the rails usually weigh about 45 lbs. per yd. The cost of building the 14½ miles of the Interlaken-Lauterbrunnen-Grindelwald line, opened in 1890, was about $44,000 per mile; and 86% of the business is from tourists, amounting to annual gross receipts of $80,000. The rack-railways up the Schynigeplatte and Wengeralp, opened in 1893, cost nearly $80,000 per mile, with their 25% maximum grades. Interlaken is 1,863 ft. above sea level; Murren has an elevation of 5,376 ft.; Grindelwald of 3,467 ft., and the summit station of the Jungfrau line will be 13,668 ft. above sea level.

◆

A COMBINED BRAKE COUPLING and angle-cock has been invented in which the cocks are automatically opened by the operation of coupling up the hose, which operation is performed by hand in the usual way. The main object is to prevent accidents caused by tampering with or neglect of these valves. The ordinary hose coupling shell is used, and is provided with an angle-cock valve connected by a link with a turn-plate on the back of the shell. This turn-plate is fitted with two claws, which grip the projecting flange of the mating shell, thus operating the valves, opening them when coupling, and closing them when uncoupling. The coupling gives the full air opening required and will couple and work with any standard coupling now in use, so that it can be introduced gradually. In case of a train parting the valves will remain open, thus releasing the air and causing the application of the brakes. The device has been tested under 100-lbs. pressure in the shops, but has not yet been in use on any cars. It is being introduced by W. & M. Cunningham, P. O. Box 340, Pittsburg, Pa.

◆

THE TERM "SEMI-STEEL," which has recently been applied by some founders to cast-iron which has been improved by remelting with the addition of some steel scrap, is strongly objected to by Dr. Richard Moldenke, of Pittsburg. In a letter to the "Iron Trade Review," he says:

> The addition of steel scrap has simply extended the upper strength limit from 25,000 to 40,000 lbs. per sq. in., and the ductility from 0.3 to about 0.75%, but has not made a new class of material by any means, all the properties being those of cast-iron. . . . The use of the term "semi-steel" conveys to the minds of modern men an impression similar to the name of some patent medicine.

◆

THE WORLD'S PRODUCTION OF GOLD in the last five years, says Mr. George E. Roberts, Director of the Mint, has amounted to $977,622,100. The industries consumed $300,000,000 of this. The stocks of gold in sight in European banks and government treasuries, from December, 1892, to December, 1897, increased about $550,000,000, or over 40%. In these five years the stock of gold in the United States increased $95,457,000; and the increase in Australia, Canada and South America was $15,000,000.

◆

THE MONEY IN CIRCULATION IN THE UNITED States, on Dec. 1, was $1,886,879,504, or nearly $165,800,000 more than on the same date one year ago. Gold coin alone shows a gain of nearly $114,500,000 in this period; standard silver dollars show an increase of $2,700,000, and subsidiary silver coin, $5,100,000. U. S. Treasury experts, on a basis of a population of 75,194,000, estimate the circulation at $25.09 per capita, of $1.70 more than one year ago.

◆

THE U. S. GENERAL LAND OFFICE, according to its report for the fiscal year ending June 30, 1898, recorded 99,806 entries of land, in all classes, covering 12,909,607 acres. The cash receipts from sales amounted to $1,391,393, and from fees and commissions the office received $853,265. The 30,293 agricultural patents covered about 4,846,880 acres, and the 1,259 mineral and mill site patents covered 31,605 acres, and railroad land grants amounted to 1,069,534 acres. The estimated unreserved and unappropriated land amounts to 579,368,274 acres, exclusive of Alaska.

◆

THE WERNWAG WOODEN BRIDGE, over the White River, at Indianapolis, Ind., was built in 1831-33, and is still standing in fair condition, according to a paper read by Mr. Edward Hill before the Indiana Engineering Society and published in the "Proceedings" of that Society for 1898. The bridge is on the old National Road, and was contracted for on July 26, 1831, by Wm. H. Wernwag and Walter Blake for $18,000, and finished in 1833. There are two spans of 170 ft. each, and the timber used was yellow poplar. Each span consists of three arched beams, which carry all the load; and each one is made of three 5½ × 11½-in. sticks placed one over the other, with 1½ ins. between sticks for packing; the arch being thus 3 ft. 1½ ins. deep. The posts are spaced 8 ft. 9 ins. apart, and are set radial to the curve of the arch. The original abutments stand, but the pier has been practically rebuilt. After 64 years continual service this bridge was straightened and repaired by the City of Indianapolis in 1897.

◆

THE ELECTRIC SEASONING OF WOOD is mentioned by the London "Builder." The timber is immersed about half its depth in a tank of water, and an electric current is applied through a metallic conductor, so arranged as to distribute the current through the whole area. In about 4 minutes the sap begins to exude at the lower end of the stick, and in 6 hours it is all extracted. In another tank an antiseptic solution is then forced into the empty pores by an electro-capillary process. The cost of doing all this is not stated.

BOOK REVIEWS.

MODELLVERSUCHE UBER DEN EINFLUSS DER FORM UND GROSSE DES CANALQUERSCHNITTES AUF DEN SCHIFFSWIDERSTAND.—Von H. Engels, Geh. Hofrath, Professor an den Technischen Hochschule in Dresden. Berlin, 1898: Wilhelm Ernst & Sohn. Paper; 14 × 10½ ins; pp. 12; two diagrams. 3 marks.

This treatise relates to experiments, made with models, upon the influence of the form and dimensions of the cross-sections of canals upon the resistance of ships in transit. Seven forms of canals were experimentel upon, with varying widths, at water surface, but constant depths; though other experiments are given in which both dimensions are widely varied in canals with inclined sides. These experiments are all tabulated and the apparatus used is illustrated. Professor Engels seemingly favors a section which is deepest at the middle; with slight upward slopes to the foot of the side-slopes.

TOPOGRAPHICAL SURVEYING. — Van Nostrand's Science Series, No. 72. Including: Topographical Surveying, by Geo. J. Specht, C. E.; New Methods in Topographical Surveying, by Prof. A. S. Hardy; Geometry of Position Applied to Surveying, by John B. McMasters, C. E.; Co-ordinate Surveying, by Henry F. Walling, C. E. Second edition; revised. New York: Van Nostrand Co. Cloth; 6 × 3⅞ ins.; pp. 210. 50 cents.

The earlier edition of this series of essays having been exhausted, the present issue has been revised in text and diagrams to agree with the latest practice. The titles are sufficiently descriptive of the purpose of the handbook. The chapter by Professor Hardy is devoted to the application of photography to surveying, and describes the general practice in the field and in the office.

TECHNICAL EDUCATION (FRANCE).—Copy of "Report on French Technical Education," by Mr. Charles Copeland Perry, recently issued by the Science and Art Department. Eyre & Spottiswoode, Government Printers, London. Pamph.; 8vo.; pp. 59. Price, three pence.

This report is divided into three parts: 1. Recent Legislation on French Primary Technical Education. 2. Schools Visited—Primary and Secondary. 3. Summary. A French law in 1880 provided for the establishment of schools "manuelles d'apprentissage," to "develop in youths intended for manual trades the requisite dexterity and technical knowledge. The law was practically a dead letter until 1888, and it was not until 1892, when a new category of schools "pratiques de commerce on d'industrie" was created, that the present system of French industrial education was seriously begun. The report is a carefully written account of the difficulties that have been encountered in arriving at a correct theory or scheme of industrial or trade education in France, of the mistakes that have been made, the beneficial results already visible, and generally of the present status of these schools.

THE NORTHWESTERN ELEVATED RAILWAY, of Chicago, upon which work has been suspended for nearly two years, is to be pushed to completion as soon as practicable. According to press reports, negotiations have been completed for a loan of $4,500,000, which will be used to continue the work. This loan was received through Blair & Co., of New York city, and is to be financed by notes of the railway company payable on or before 18 months, with interest at 5%. To secure the loan the railway company will deposit with the Illinois Trust & Savings Bank as trustees, $5,000,000 in 5% first mortgage gold bonds and $5,000,000 in preferred stock, representing the entire issue of both classes of securities. As a guarantee that the railway company will at once proceed with the construction of the road and have it completed by Jan. 1, 1900, it has deposited $100,000 with the Comptroller of the city of Chicago. The Northwestern Elevated Ry. will extend from the business district into the northern section of the city of Chicago, and will be about 6⅔ miles long. The motive power will be electricity. The foundations for a considerable part of the line are completed and much of the steel work is ready for erection. A full description of the proposed road was published in Engineering News, of Sept. 5, 1895.

◆

A PLANT FOR THE MANUFACTURE OF STEEL cars is about to be built by the Carnegie Steel Co., Ltd., It will have a capacity of about 40 cars per day, and will include a large axle forge. The company has purchased a large track of land on the south bank of the Monongahila river, west of Homestead. It is about 1½ miles long by from ⅛ to ¼ mile wide. With this new track the company will own over seven consecutive miles of land on the river. The establishment of a car works by the Carnegie company is a notable example of the tendency of iron and steel manufacturers not only to control their own coal and ore supplies and their own transportation, but also to carry the manufacture of their product to the final shape in which it is to be used, instead of selling it in intermediate forms, such as bars, beams and plates.

◆

PROPOSALS FOR TÚRBINES for the water power electric plant of the Lake Superior Power Co., at Sault Ste. Marie, Mich., will be received until March 1, 1899. A full description of the canal, penstock and power-house construction for this plant was published in Engineering News, of Aug. 4, 1898. The turbines which are required must be capable of developing in penstock units, composed of two or more turbines, with a head of 16 ft. at the penstock entrance and with 391 cu. ft. of water per second, 568 HP. at the end of a shaft, which revolves 180 times per minute. The details of construction, type, size and number of the turbines are left to the bidder. The proposals are to be submitted to the Chief Engineer, Lake Superior Power Co., Sault Ste. Marie, Mich.

A $9,000,000 LOAN AT NEW ORLEANS for water supply, sewerage and drainage will be submitted to popular vote on Feb. 2. If the vote is in the affirmative, the proceeds of the loan will be divided equally between the works named. The city is already part owner of the water-works, and work on the drainage system is under way. A franchise for a sewerage system was granted a number of years ago, a company organized and some pipe laid. The company has been in the hands of a receiver for some time.

◆

THE SANITATION OF SANTIAGO DE CUBA requires strong measures to impress upon the inhabitants the force and meaning of the new regulations. Major Barbour, with his force of 126 men, has dug out and carted away very much of the accumulated filth of centuries, and whitewash, lime and disinfectants have greatly improved the sanitary conditions of the city. But doors of houses have had to be smashed in getting at filthy yards, and natives who insist upon turning the streets into sewers are publicly horsewhipped in the streets. Eminently respectable citizens were at first sentenced to aid in cleaning the streets, when convicted of defiling them; but all classes have completely surrendered now, says Mr. Robert P. Porter, in his report as Special Commissioner, and they begin to appreciate the common good to result from the new regime. Several important streets have been repaved and all the public buildings thoroughly cleaned. The law courts have been reorganized; and the municipal taxes, formerly diverted into other channels by Spanish officials, are now being devoted exclusively to local improvement. Public roads are greatly needed in the Province, as practically none exist worthy of the name. Mr. Porter says there is a nominal revenue of nearly $5,000,000 annually, in Santiago Province, coming from internal, industrial, professional and licensing taxes, and this could well be devoted to local improvement.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred Dec. 21 on the Pennsylvania R. R., at Colonia station, near Rahway, N. J. Two persons were killed and six seriously injured, all of whom were on an express known as the "Pittsburg Flyer," due at Jersey City at 6:21 a. m. Owing to a dense fog the Southern express, from Tampa, due at Jersey City at 6:43 a. m., ran into the rear of the Pittsburg express, which was being held by the block signal.

◆

TWO WATER MAINS BURST IN CLEVELAND on Dec. 21. One was 30 ins. and the other 8 ins. in diameter, the breaks being close together. A large hole was washed out in the street and some other damage was caused by the water.

◆

HEAVY MARINE LOSSES, for 1898, are reported by marine insurance men. A list of the 26 most important total losses foots up at $4,325,000 for the approximate hull value, and $7,397,500 for the freight cargo. In this list "La Bourgogne" figures at $800,000 for the ship and $500,000 for cargo; and the "Mohegan" at $700,000 and $150,000, respectively. On the American lakes, 56 vessels were lost, with a tonnage of 29,194 tons, valued at $2,600,000.

◆

THE SINKING OF A PIECE OF STATE ROAD in Swampacott, Mass., is reported in the Massachusetts papers. A stretch of road has given some trouble by continued settling, requiring the addition of new material from time to time to keep it to grade. On Dec. 8, as filling was in progress, alarm was caused by heavy settlement. The settlement continued until quite a pit, filled with water, is said to have formed over a length of 100 ft. of what had been roadway. It appears that an embankment was built on a thin crust of solid material; that settling began, and was made worse by each successive filling, until finally the crust gave way under the load. The road was built by, or under the direction of, the Massachusetts State Highway Commission, whose headquarters are at Boston.

◆

THE TRANS-CASPIAN RAILWAY, says the London "Times," has been extended from Merv, 300 miles southeast of Khwa, to Kushk, in the Jamshidi province of Afghanistan and within 95 miles of Herat. The first train passed through on Dec. 16.

◆

THE MOMBASA-UGANDA RAILWAY, in East Central Africa, is completed for 250 miles, from Mombasa, on the Zanzibar coast. The terminus will be on the north shore of Lake Victoria. The line is one meter gage, and for fully 200 miles it traverses a waterless desert. At 131 miles from Mombasa, at Tsavo, it reaches an elevation of 1,900 ft. above sea-level; at Kibwesi, 193 miles, the elevation is 3,000 ft.; and at Kikuyu and Mau the line will be 7,700 ft. and 8,300 ft., respectively, above the sea. The road was constructed under great difficulties; but the portion completed is being operated with first, second and third-class cars, moderate fares and with time-tables arranged on the 24-hour system.

◆

GEOLOGIC FOLIOS, or the parts of the geological map of the United States already surveyed and mapped by the U. S. Geological survey, are on sale at the offices of the Survey, at Washington, D. C. A circular has been prepared, and will be forwarded on application, showing for each folio, the state, the limiting parallels and meridians, the area covered, and the price, which in nearly all cases is 25 cts. The area covered by a folio is usually 1,000 sq. miles; 46 folios are ready for distribution and 15 are nearing completion.

◆

TOPOGRAPHIC MAPS OF NEW ENGLAND are on sale by the U. S. Geological Survey as follows: Massachusetts, Rhode Island and Connecticut are completely surveyed and mapped; of Maine, 24 sheets are published; of New Hampshire, 19 sheets, and of Vermont, 23 sheets. The whole number of published sheets for New England is 133; of which Massachusetts has 55; Rhode Island, 15, and Connecticut, 34. The unit sheet is 16½ × 20 ins., covering 1-16th of a "square degree," embracing an area of about 220 sq. miles, on a scale of 1:62.500, or about one mile to one inch. They are sold for 5 cts. per sheet, or 2 cts. each for 100 or more sheets. On application a circular will be forwarded showing just what parts of the three unfinished states are surveyed; and on this circular, the separate sheets of all work done are so designated that maps for any desired section can be ordered.

◆

SHIP DRAFTSMEN are wanted at various shipyards, and on Feb. 7 the U. S. Civil Service Commissioner will open a competitive examination of applicants. The pay is $5 per day for draftsmen, and $4 for assistant draftsmen. All persons desiring to compete should at once write for application blanks and directions to the U. S. Civil Service Commission, Washington, D. C.

◆

SURVEYS OF PORTO RICO HARBORS are to be made by the U. S. Coast and Geodetic Survey, and the survey steamer "Blake" sailed from Baltimore on Dec. 22 with a party of engineers. The government will extend this work as rapidly as possible to the whole coast of Cuba and Porto Rico, which is either now very poorly mapped or has never been surveyed at all.

◆

THE PROPOSED LAKE ERIE-OHIO RIVER SHIP canal is not believed in by the Pittsburg Chamber of Commerce, according to the "Commercial Gazette," of that city. At a recent meeting of the directors of the Chamber, a resolution was presented favoring the incorporation of the canal company by Congress and urging Congress to pass the bill. This resolution brought out vigorous opposition. Capt. Jno. F. Dravo said that the plans for the canal call for a depth of 15 ft., whereas nearly all lake vessels draw from 18 to 20 ft.; and at the proposed terminus of the canal, at Davis Island, there is only 12 ft. of water. To make the canal available, locks 1 and 2, in the Ohio slack-water navigation, would have to be rebuilt, and the river would have to be dredged from the Island to McKeesport. This dredging would destroy Pittsburg harbor, as the water is now held by the natural bar at Brunot's Island, which bar would have to be cut through. Mr. Dravo criticised the estimated cost as too small, and finally said that the building of the Carnegie railway line to Lake Erie had killed the canal as an enterprise. Other directors spoke in a similar vein, only one favoring the canal. In the interest of the subscribers to the canal fund, the resolution was finally adopted, although a number of the members did not vote.

◆

COAL FOR AMERICAN WARSHIPS, to the amount of about 500,000 tons, is to be systematically distributed along the Atlantic, Gulf and Pacific coasts, at Manila, Honolulu, Pago-Pago, Guam, etc. In addition, at least 50,000 tons more is always available at either Hampton Roads or New York. The government now possesses 17 armed colliers, with an aggregate carrying capacity of 50,000 tons.

◆

THE FIGHTING FORCE OF THE U. S. NAVY, at its maximum on Aug. 15, 1898, according to the report of the Secretary of the Navy, was made up as follows: First class battleships, 4; second class, 1; armored cruisers, 2; coast-defence monitors, 6; armored ram, 1; protected cruisers, 12; unprotected cruisers, 3; gunboats, 18; dynamite cruiser, 1; torpedo boats, 11; vessels of old Navy, including monitors, 14. Auxiliary Navy: Cruisers, 11; converted yachts, 28; revenue cutters, 15; lighthouse tenders, 4; converted tugs, 27; converted colliers, 19; miscellaneous, 19. This is a total of 73 in the regular navy, and 123 in the auxiliary fleet, or 196 vessels in all. This fleet was manned by 24,123 enlisted men. There were 856 volunteer officers of all grades in service during the war; 456 of these ranking with the line, and 205 were engineer officers. There are now under construction: 8 first-class battleships; 4 coast-defence monitors; 1 training vessel; 1 sheathed cruiser; 16 destroyers; 22 torpedo boats; 2 steel tugs; 1 submarine boat; or 55 warships in all.

◆

A 40-FT. CHANNEL TO NEW YORK HARBOR is advocated by New York business and marine interests before the House Committee on Rivers and Harbors. This channel, by way of the East Channel, would cost $5,840,000, and could be finished in ten years. A 35-ft. channel would cost $4,510,000, but in view of the rapid increase of the draft and dimensions of ocean steamers the deeper channel is recommended.

NEW RUSTIC STONE ARCH BRIDGES IN THE NEW YORK STATE RESERVATION AT NIAGARA FALLS.

The Commissioners of the New York State Reservation at Niagara Falls have been replacing several of the older bridges by rustic stone arches. The largest of these, which has just been completed, is one connecting Goat Island with the First Sister Island, and it takes the place of the old suspension bridge familiar to every visitor to Niagara Falls. This older bridge was too narrow for the traffic, and being located some feet above the present stone arch, it obstructed the view of one of the prettiest of the small water falls at Niagara. The new bridge was so built that the fall can be seen, and the channel was deepened above the bridge to increase still further the beauty of the scene.

RUSTIC STONE ARCH BRIDGE CONNECTING GOAT ISLAND AND FIRST SISTER ISLAND, NIAGARA FALLS, N. Y.
Vaux & Emery, New York, N. Y., Architects.
W. A. Shepard & Co., Niagara Falls, N. Y., Contractors.

The span of the arch is about 60 ft. and the outside width is 16 ft., with parapet walls 2 ft. thick. The arch is built of "native" stone, used undressed on the face and laid with ½-in. joints in Giant Portland cement. The rock-face projects about 3 ins. beyond the plane of the joints, and the general character of the masonry is well shown in the photograph. In construction the arch was laid uniformly from both ends, and all backing, wing walls, etc., are made of first-class random rubble-work laid in courses and well bonded. The top of the arch and part of the abutments have a concrete backing plastered over with cement, and on this is laid a three-ply damp-course made of tarred felt and asphaltic cement. Four 3-in. weepholes through the abutments carry away any moisture reaching the damp-course. At each end of the arch are projecting bays, and from these the wing walls extend. The parapet-wall is made of two courses of rock-face stone, and a cement walk completes the bridge. Judging from the photograph alone the chief criticism to be made upon this arch is that it is somewhat too massive in appearance for the span and site.

The architects were Vaux & Emery, of New York, and the work was done by W. A. Shepard & Co., of Niagara Falls, at a cost of about $8,000. We are indebted to Mr. Orrin E. Dunlap, of Niagara Falls, for the photographs and information used.

A WOODEN LINING FOR SHIELD-DRIVEN TUNNELS.

In the construction of the sewerage system of Melbourne, Australia, a large amount of tunnelling was necessary; in all, 37,145 lin. ft. of sewers, from 3 ft. 3 ins. to 9 ft. internal finished diameter, were built with the assistance of shields. Compressed air was employed in 5,250 lin. ft. of this work, and cast-iron, wood, concrete and bluestone blocks were used for lining. The cast-iron, with concrete lining, was first adopted, but the great extent of the work demanded some more economical construction, and concrete and bluestone blocks were next tried. This latter system of lining was not found to be generally suitable, especially in wet grounds and in the larger diameters, and, for a time, iron lining was again employed. In the last shield tunnel work, however, a system of lining with wood, devised by Mr. George Henry Dunlop, M. C. E., of Melbourne, was successfully adopted. This tunnel was finished in concrete, as with the cast-iron lining.

For two lengths of sewer, one amounting to 2,000 lin. ft. of 6 ft. 9 in. tunnel and the other 1,250 lin. ft., 7 ft. 6 ins. in diameter. Mr. Wm. Thwaite, M. Inst. C. E., and Engineer in Chief of the Melbourne Metropolitan Board of Works, had two designs prepared, one using cast-iron lining of the usual type and the other the wood lining proposed by Mr. Dunlop. The two constructions were deemed of equal efficiency for use with shields and alternative bids were received upon the two plans. As a result, the lowest bid for the cast-iron was $164,000, and $121,300 was bid for the wooden lining. The bid for the wood lining was accepted; but it should be said in connection with these prices that a considerable part of each sum was chargeable to shafts and other non-tunnel work common to both.

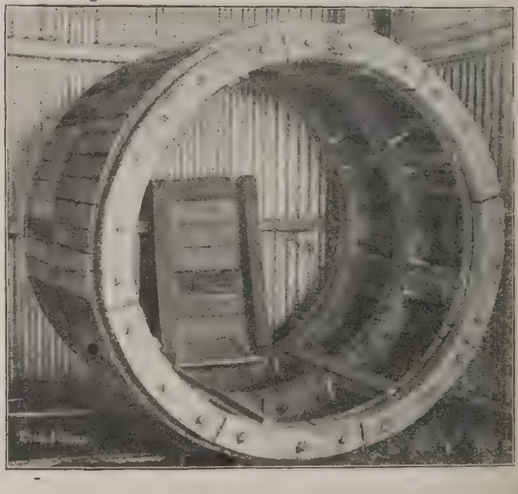
The construction of the wooden lining is shown in the illustration given for a 4 ft. 3 in. sewer. The wooden lining is built up in successive rings, about 2 ft. broad, each ring being made of eight segments fastened together by the lagging nailed to them. In the sewers here shown the ribs were made of 5×3 in. material, cut to the circle and radial lines, and the lagging was 1½ ins. thick. The sections are put together outside of the tunnel, and are laid up like blocks in the tunnel; and as they are put in place the rear-rib is made to break joint with the rib already laid, and the two are firmly bolted together, so as to act as one piece. As a consequence, each complete rib is actually made of two sets of the 5×3 in. timbers. In construction, freshly tarred felt is placed between the abutting ribs. The bolts used are ¾-in. diameter, with square heads and nuts, and washers 2½ ins. square and ¼-in. thick.

To take up the thrust of the rams used in forcing the shield ahead, eight stout struts, or thrust-blocks, are fitted between the ribs with wedges, and in continuous lines extending as far back from the shield as may be necessary. These struts are removed before the concrete is put in place and they may be used over again. In these Melbourne sewers Australian hardwood was employed, and red-gum, ironbark, and box was specified for the ribs. In the 7 ft. 6 in. circular sewers the ribs were made of 6×3 in. red-gum; the lagging was 1½ ins. thick, with 10 pieces to each of the eight segments; the thrust-blocks were 8×6 ins. in section, and ¾-in. bolts were used throughout. Each ring was 2 ft. long, and the final concrete lining was 14½ ins. thick, with a rendering of ¾-in. of neat cement mortar on the inner surface. The ground passed through was largely a sandy clay, with a considerable section containing only sand heavily charged with water. This tunnel was carried under several railways, a small creek, and the brick abutment of a bridge.

In designing this wood lining the purpose is to make the ribs, taken in connection with the lagging, sufficiently strong to resist the outside pressure, for a considerable time at least; and as a matter of fact, at Melbourne, sometimes as much as 2,000 lin. ft. of the wood lining was built ahead of the concreting work. The chief advantage claimed for the wood over the iron lining, aside from economy in cost, is the better subdivision of duties to be performed by the ribs and lagging. Any tunnel lining, when unequally loaded, depends for its rigidity upon its ribs, or flanges. In cast-iron lining the circumferential flanges usually contain from 25 to 33% of the whole metal, and it is difficult if not impossible to separate the duty performed by the flanges and the metal connecting them. In a properly designed wood lining, the ribs would contain from 50 to 66% of the total wood; and this material and the span and thickness of the lagging can be readily and certainly proportioned to sustain any estimated compression. The use of the continuous thrust-blocks prevents the rings from being distorted by ram-action, and for all practical purposes the wooden lining is as rigid as one of cast-iron.

It is true, that there is an unusually large number of joints in the wood lining. But the swelling of the wood in damp ground will tend to prevent leakage; and if it were necessary, the whole outer surface of the ring could be covered with thin metal or other waterproof material—even overlapping the joints of rings. While the timber lining requires a slightly larger shield, this is compensated for by the lighter weights to be handled in wood construction. The lagging, if closely fitted, will swell, and to a considerable extent act as an arch in transmitting pressure to the ribs. In fact, the wooden lining used at Melbourne was found to deflect less under pressure than the cast-iron which it replaced; and it well withstood heavy and unequal ram pressures.

In large tunnels, lined with cast-iron, it is a common practice to omit the concrete, or only to cover the flanges with concrete, on the assumption that the life of the cast-iron used is equal to that of brick or concrete. In construction of this kind to be used in connection with electric power, there is now a suspicion of possible serious trouble from electrolytic action. Based upon the experience in Melbourne, the inventor of the new system believes that an all-brick or concrete tunnel could be thus built at a less cost than for an



General View of the Dunlop Wood Lining for a 4-ft. 3-in. Sewer, Built at Melbourne, Australia.

(This sewer, when finished, had concrete walls 13 ins. thick; the wooden ribs being imbedded; but the longitudinal struts were first taken out.)

unlined cast-iron tunnel, and it would be totally free from danger of the kind mentioned.

The following comparative tables of quantities are given from actual experience with the two systems:

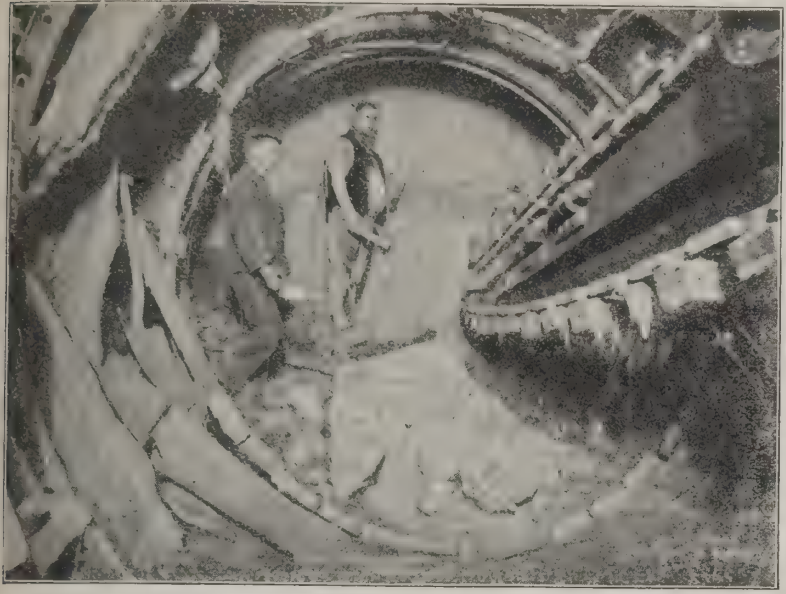


FIG. 1.—TUNNEL EXCAVATION IN THE CENTRAL LONDON RY., LONDON, ENG., SHOWING INTERIOR OF GREATHEAD SHIELD AND THE ELECTRIC CHAIN CUTTER USED.

Quantities Per Lineal Foot for a 7-ft. 6-in. Circular Sewer.

	Cast-iron lining.	Wood lining.
Cast iron, lbs.	1,820	....
Bolts, lbs.	56	34
Concrete, cu. yds.	1.07	1.23
Rendering, sq. yds.	2.70	2.70
Wood ribs, B. M.	....	82
Boarding, B. M.	....	55
Rails, lbs.	....	6

To the above must be added labor and plant.

Quantities Per Lineal Foot for 4-ft. 3-in. Sewer.

	Cast-iron lining.	Wood lining.
Cast iron, lbs	1,012	....
Bolts, lbs.	54	29
Concrete, cu. yds	.40	.50
Rendering, sq. yds	1.53	1.53
Wood ribs, B. M.	....	40
Boarding, B. M.	....	34
Nails, lbs.	....	2.3

Add labor and plant for erection.

Any further details regarding this process may be obtained from Mr. Wm. H. Breithaupt, M. Am. Soc. C. E., 35 Nassau St., New York city, who is the representative of the inventor, Mr. Dunlop, in the United States.

SOME NOTES OF THE CENTRAL LONDON RAILWAY.

By Gilbert Rosenbusch, M. E.*

While conducting tests on the first elevator installed by the Sprague Electric Elevator Co., of New York (Eng. News, Nov. 3, 1898), for the Central London Ry., it was my good fortune to be able to inspect this interesting underground railway, and to procure, through the courtesy of Mr. Cowperthwaite, assistant to Sir Benjamin Baker, the chief engineer, some photographs of the tunnel work. These are here reproduced as being characteristic and of interest to American engineers.

This road, it will be remembered, consists of twin deep level tunnels, constructed with the aid of the well-known "Greathead" shield system. The principal reasons for using twin tunnels with a single track in each, one for up trains and one for down trains, in preference to a double track single tunnel were: First, the lower initial cost; second, ability, by reason of small diameter and change of relative position, to remain under the roadway proper; thus complying with the acts of Parliament which precluded the right of way under private property; third, avoidance of the possibility of collisions as the result of derailment; fourth, maintenance of ventilation due to the draft caused by continued passage of trains in one direction only.

The objections to this method were: First, increased cost of maintenance of way, inspection and signaling; second, increased cost, and complication of inlet and egress passages at stations, with relatively greater discomfort to passengers; third, inability to switch over en route.

In the construction, the need of rapid acceleration and quick braking, without greatly increased power consumption, or wear and tear on the running equipment, was provided for by "peaking" the road bed at each station, the approaching grade being 1 in 30 and the leaving grade 1 in 60. Otherwise, the road bed is practically level; the depth at various stations varies considerably, being from 40 ft. to over 100 ft. The majority of the work being through black London clay, which is extremely hard and dense, air pressure is generally dispensed with, being used only at the Shepherd's Bush end, where gravel was encountered, and again where the work went under the supporting piers of the Holborn Viaduct at Chancery Lane, where a pressure of 20 lbs. per sq. in. was used. At these places air locks were necessary, and Fig. 2 shows the entrance to one of the air lock chambers. These entrances are boiler shells about 7 ft. in diameter, and about 10 ft. long, or sufficiently large to hold two loaded muck wagons. The doors are hinged, and, of course, open only toward air pressure, locks being found unnecessary. This air chamber is held in place by a brick bulkhead, 12 ft. thick, also shown in the figure, which takes the pressure of the air on the remaining area of the tunnel (about 165 tons).

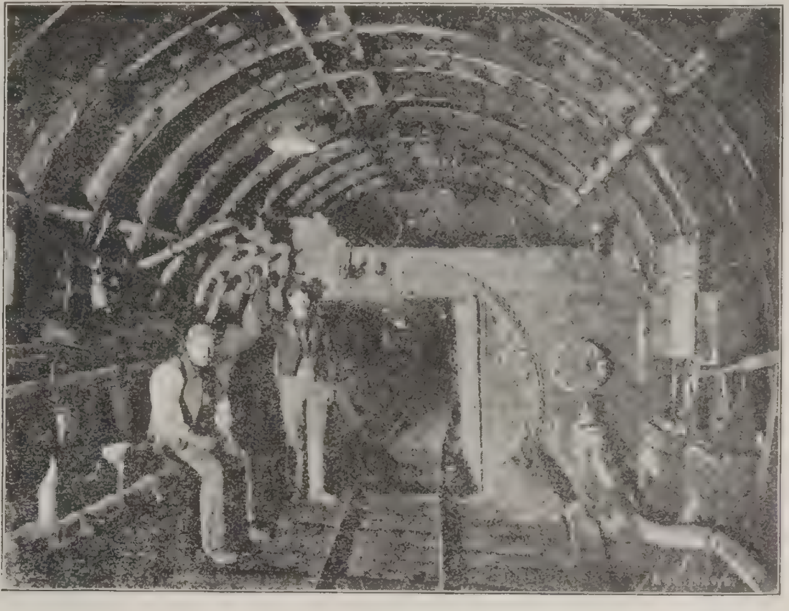

FIG. 2.—ENTRANCE TO AIR LOCK IN 11½-FT. TUNNEL, CENTRAL LONDON RY.

The men employed work on 8-hour shifts, being taken only with a doctor's certificate of soundness. They receive pay for time and a third, and are furnished with hot coffee at the air locks when they desire it.

The air compressors are situated in the open on the street level, the supply pump opening being kept close to the heading, thus insuring a constant supply of fresh air. The air-lock tender has telephonic communication with the compressor room.

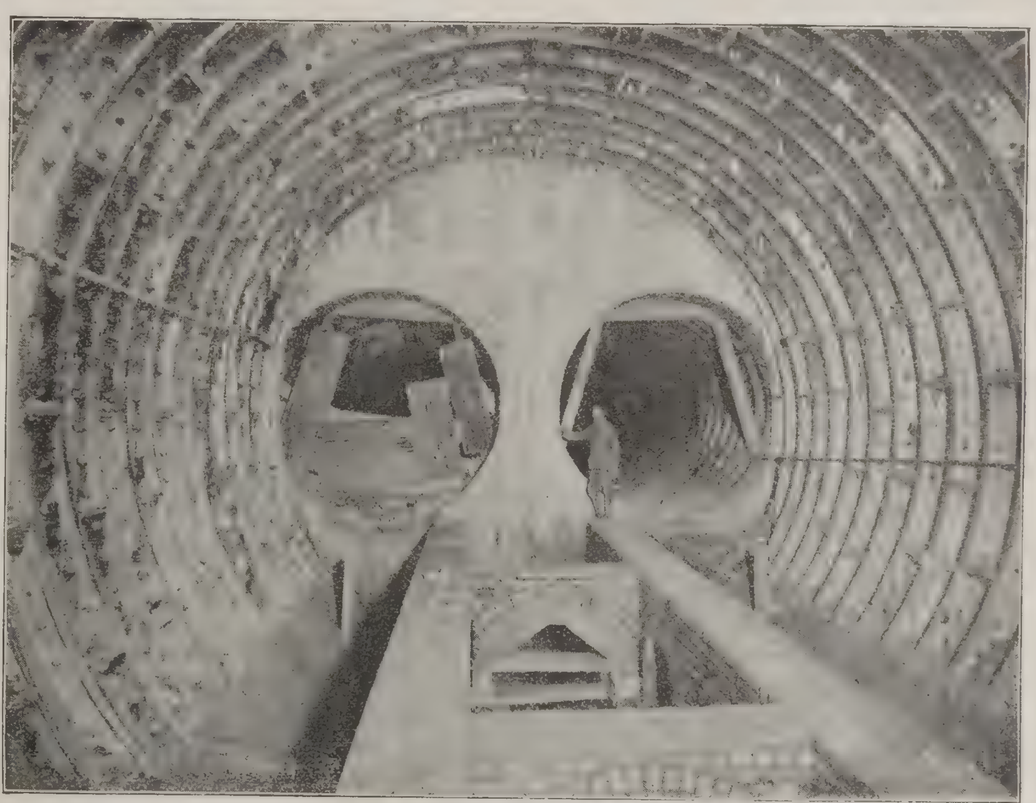

FIG. 3.—VIEW SHOWING LARGE TUNNEL AT STATIONS AND CONNECTION WITH SMALL TUNNELS.

The tunnels are driven by a steel shield worked with six hydraulic jacks operated by a hand pump and cutting out a tunnel 1 in. larger in diameter than the outside of the tunnel lining. This lining is built up of cast-iron rings 18 ins. wide, and consisting of 6 segments and one key, the latter having parallel sides is slipped in from the front after the 6 segments are in place. These segments weigh in the neighborhood of 5 English hundred-weight (560 lbs.), and the contract for furnishing them was sublet to a number of foundries, because of the enormous quantity of cast iron involved. In the small tunnels they are erected by hand and bolted together in place, following as closely behind the advancing shield as working room will permit. The finished inside diameter is about 12 ft., with a working diameter of 11½ ft. The resulting series of circumferential and longitudinal joints are rust calked with sal-ammoniac and metal filings, and then carefully grouted. In places where the soil was of softer character a traveling bucket excavator, shown in Fig. 1 (also Eng. News, May 19, 1898), was used to great advantage, the moving mechanism being mounted on a wooden boom so as to be pointed at any spot desired, like a derrick.

---

*Engineer with the Sprague Electric Elevator Co., 44 Broad St., New York city.

As the shield bores 1 in. in diameter larger than necessary, a ½-in. recess is left all round the iron which permits of an outside water-tight lining. This is done by forcing through holes in the segments by air pressure a grout of hydraulic lime which sets in about 15 minutes, thus affording additional proof against the entrance of water to the tunnel.

The road bed proper is built up in the tunnel to the proper level by filling in with concrete, with a top layer of cement, on which are laid longitudinal wood stringers upon which the 100-lb. rails, are bolted. The resulting low head room precluded the use of motor cars unless the car bodies were made like those used by the Waterloo & City road, in which, however, valuable seat room is sacrificed, owing to the large and high motor required. The company, therefore, adopted a locomotive system. (Eng. News, June 9, 1898.)

At stations the tunnel is enlarged for a length of about 500 ft. to 21 ft. in diameter to take a platform. An excellent idea may be gotten of this arrangement from Fig. 3. It will be noticed that where the twin tunnels enter the station tunnel, the latter is, for a short distance, considerably larger in diameter. This enlargement was allowed for the setting up of the shield.

Of course where the tunnels are on different levels, and have different vertical center lines, two enlarged station tunnels are necessary. These station tunnels, which are constructed exactly similarly to the smaller road tunnels, will be lined with a white vitreous material 1 in. in thickness bedded into cement, and having the effect of, and doing the duty of, glazed brick at a much reduced cost.

The station tunnels were also constructed with shields, which were made 22 ft. 10 ins. in diameter and 6 ft. in length. They were built of two cast-iron rings, strengthened and braced by steel stringers, running vertically and horizontically. A central diaphragm of steel plate was bolted between the two cast-iron rings. Each ring was made up of 22 segments, and there was a hydraulic ram for each segment.

LIFE ON A RAILWAY SURVEY IN THE WOODS.

We are indebted to Mr. E. T. Abbott, of Minneapolis, for a photograph, reproduced herewith, of a railway location party equipped for a fifty-mile survey in the forests of Minnesota and Wisconsin, last October. In a breezy letter accompanying the photograph, Mr. Abbott wrote:

> Those who take their luxurious ease in parlor cars, after the road is built, ought to get a taste of the life of the men who first laid out the route over which they ride in such comfort. At this time of year a "bell-ringer" is necessary in surveying in the woods to prevent some city "pot-hunter" taking a shot at you for a deer. Notwithstanding our precautions, twice during the fall some one of my party has been fired at with a Winchester rifle. Thanks to bad marksmanship, however, no harm was done. Wolves are numerous, and we have occasionally had to keep fires all night to keep them away from the camp.
>
> It may be of interest to know the contents of the kit of supplies, which we packed on our backs in our fifty-mile survey, so I append it as follows: One 12×14-ft. 10-oz. duck tent, 14 pairs blankets, 2 axes, 1 tin bake oven, 1 frying-pan, 6 tin cups, 6 tin plates, 6 knives and forks, 6 spoons, 1 bread pan, 1 dripping pan, 1 wash basin, 25 lbs. flour, 25 lbs. ham, 10 lbs. bacon, 6 lbs. corned beef, 3 tin pails, 2 lbs. tea, 10 lbs. coffee, 5 lbs. butter, 10 lbs. mess pork, 10 lbs. sugar, 20 lbs. canned peaches, beans, baking powder, condensed milk, etc.; 25 lbs. extra clothing, rubber sheets, etc., etc. No guns, revolvers, cards or whiskey.
>
> All the above was carried in the packs shown in the photograph.

The bags with shoulder straps, which are shown in Mr. Abbott's photographic view, call to mind another form of "pack," the making and carrying of which are fully illustrated by the sketches on the opposite page. To make this pack a tarpaulin and a "tump-line," or "pack-strap," are needed. The tarpaulin may be from 7 to 8 feet square, and is useful for many other purposes, particularly to lay on the ground under the blankets. The tump-line consists of a head-strap of leather about 3 ins. wide by 2 ft. long, to each end of which are attached leather thongs about 7 ft. long. A pack so made is thoroughly waterproof and may be varied in size and form to suit the nature of its contents.

BLAZING THE WAY FOR THE PALACE CAR; RAILWAY SURVEY PARTY EQUIPPED FOR A FIFTY-MILE TRIP THROUGH THE WOODS.

Mr. Abbott does not state what time was spent on his survey, but his list of provisions shows that he carried 25 lbs. of flour and about 50 lbs. of meat. This proportion is not in accord with the experience of a member of the staff of this journal who has spent some thirty months surveying in six different seasons, on Canadian Government work. His notes show the average consumption of the staples to be 2 lbs. of flour and 1¼ lbs. of preserved meat (salt pork, ham, etc.) per man per day.

MARITIME COMMERCE; PAST, PRESENT AND FUTURE.

At the fiftieth meeting of the American Association for the Advancement of Science, at Boston, Mass., Mr. Elmer L. Corthell, M. Am. Soc. C. E., presented a paper with the above title, of which the following is an abstract:

The purpose of the paper is to note the changes that have taken place in the last half century in the methods of maritime transportation, from sail to steam, and from wood to iron and steel. It deals with the effective carrying power of the commercial navies of the world, the dimensions of ocean vessels and the facilities of harbors and ports. Mr. Corthell, from such data as are available and within the limits of future and unforeseen conditions, attempts to estimate the dimensions of vessels, and the requirements in harbor approaches fifty years hence. He does this so that those having to do with public works of this description may at least form some idea of what may be demanded of them in the future. He plots these results in diagrammatic curves; and he approximately projects these curves forward twenty-five or fifty years. In obtaining this information, he has personally visited some forty ports of Europe; consulted those qualified to give an opinion, and has carefully studied a great list of authorities given in the paper. The chief end of all these studies is to ascertain the depth and dimensions to be given to sea-approaches to harbors, to meet the possible demands of the next half century following increased dimensions in ships themselves.

In 1848, Lloyd's Register of British and Foreign Shipping shows that the commerce of the world was almost altogether carried in sailing vessels built of wood. There were only 121 steamers afloat in that year, and only 36 of these were built of iron; and of the 10,579 sailing vessels described only 79 were built of iron. The development prior to this date had been slow and tentative. The first attempt to propel vessels by steam power was made in Barcelona, Spain, in 1543; then in France in 1707; in England in 1736; in the United States by John Fitch in 1787; then by Robert Fulton in 1807, and on the Clyde in 1812. At the latter date steam navigation may be said to have been fairly under way. The first steamer to cross the Atlantic was built in the United States, at Savannah, Ga., in 1819, by John Stevens. But steam was only an auxiliary to sails. The first British Atlantic steamer was the "Royal William," built in Quebec in 1831, and it crossed in 1838. The first Cunarder crossed in 1840; the first steamer of the Collins Line in 1848; and the first vessel fitted with a screw propeller was the "Francis B. Ogden," built by Capt. Ericsson in 1837. The first screw steamer to cross the Atlantis was the "Great Britain," in 1845, and she was also the first iron steamer to cross the ocean.

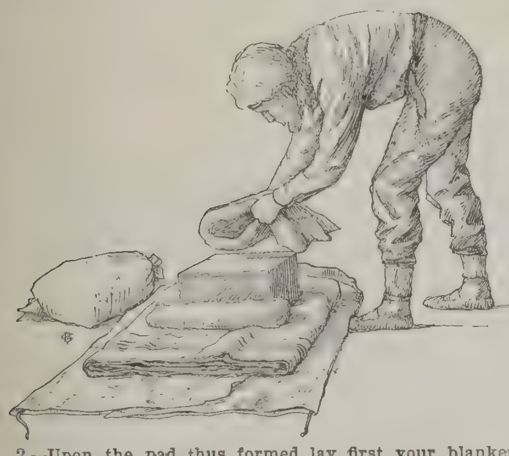
The fastest passage, between Liverpool and New York, up to 1840, was made by the Cunarder "Europa," in 11 d. 3 h.; in 1852 this time was reduced by the Collins Line's "Baltic" to 9 d. 13 h. The "Royal William," above referred to, made the passage from Quebec to London in a little over 40 days. She was 160 ft. long, 44 ft. beam, 17¾ ft. deep and 363 tons' register, or about the size of an ocean tug of the present day.

Mr. Corthell does not note the comparative dimensions of modern ocean steamers, their sailing time, etc., as these are matters of record elsewhere, but he proceeds to generally point out the effects of the continued increase of steam navigation, in all lines, in the last fifty years. The increase in the number, size, speed and economy of steamships has augmented the amount and decreased the relative value of goods transported. This economy makes it now possible to transport goods of low values long distances; it has brought new countries into the commercial field, and the sources of supply are brought nearer to the markets. The beneficial change is not confined to the sea, as canals and railways have in a similar manner covered immense distances on land and provide transportation for districts far removed from the sea-board. And in the case of railways, the gain is in continually increased hauling power and car capacity; the latter having increased from an average of 10 tons to 30 tons, and even 50 tons.

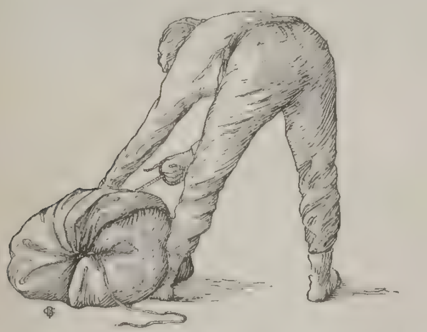
In 1848, coal, grain, timber and metals, all articles of relatively low values, were transported in the ratio of 9,000,000 tons of these to 7,000,000 tons of more valuable merchandise. This ratio is now as 120,000,000 tons is to 65,000,000 tons of the more valuable goods. This decrease in transportation cost has doubtless had very much to do with the notable fall in prices in these fifty years, as the average prices of all articles of consumption were about twice as much in 1848 as in 1898. In this period the effective horse-power of all steam vessels afloat has increased from 2,000,000 to 60,000,000 I. HP.

In referring to the diagram given in the paper, we find these curves of special interest, made by taking the average of 20 of the largest steamships; Average length: 230 ft. in 1848; 541 ft. in 1898; possible 1,000 ft. in 1948. Average beam: 36 ft. in 1848; 61 ft. in 1898; 100 ft. in 1948. Average depth: 23 ft. in 1848; 39 ft. in 1898; 43 ft. in 1948. Average loaded draft: 19 ft. in 1848; 29 ft. in 1898; 33 ft. in 1948. Average speed in knots: 9 knots in 1848; 18 knots in 1898; 24 knots in 1948. Average tonnage: 1,430 tons in 1848; 10,717 tons in 1898; 30,000 tons in 1948. Speed in knots of the fastest steamships: 10 knots in 1848; 22 knots in 1898; 30 knots in 1948. Number of dry-docks, 500 ft. long and more: 23 in 1881; 75 in 1898; 176 in 1948.

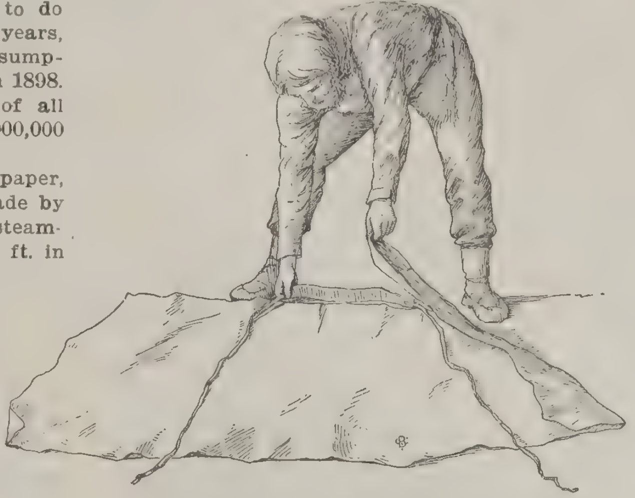
The curves of general features give the following general rate of growth: Total number of sailing vessels, 56,281 in 1873; 29,315 in 1898; 10,800 in 1948. Total tonnage of sailing vessels, 14,185,836 in 1873; 8,894,732 in 1898; 3,241,000 in 1948. Average tonnage of sailing vessels, 252 tons in 1873; 303 tons in 1898; 300 tons in 1948. Total number of steamships, 242 in 1848; 5,148 in 1873; 11,271 in 1898; 16,685 in 1948. Total tonnage of steamships, 74,700 in 1848; 4,328,193 in 1873; 17,889,006 in 1898; 45,000,000 in 1948. Average tonnage of steamships, 310 tons in 1848; 841 tons in 1873; 1,587 tons in 1898; 2,700 tons in 1948. Power of steam and sail, in millions of tons, on the basis of one ton of steam equivalent to three tons of sail, 16½ million tons in 1848; 27 millions in 1873; 62½ millions in 1898; 138 millions in 1948. Weight of seaborne commerce, in millions of tons, 26½ million tons in 1848; 113 million in 1880; 201 million in 1898; 435 million in 1948.



2.—Upon the pad thus formed lay first your blankets; then anything hard you have to pack—say an instrument box; on top of this place all the soft things you can.



3.—Fold the blanket and tarpaulin from top and bottom over all; then take hold of the head-strap and each end of the tie-strap, alternately, haul them tight until you have puckered the ends of the tarpaulin close over the contents. Make a half-hitch of the tie-strap round the head-strap at either end.

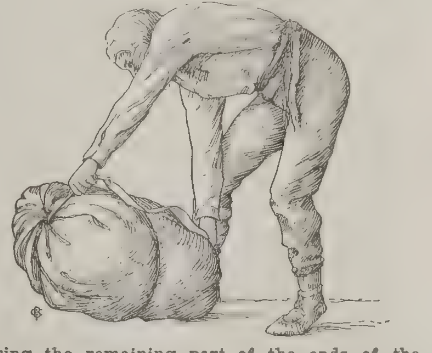


1.—First spread your tarpaulin; lay your tump-line across it, with the tie-straps from two to three feet apart, depending on the size of the pack; then fold the ends of the tarpaulin over the tie-straps.

If the growth of the tonnage in the principal ports of the world be compared with the general increase of commerce, we have additional evidence of the remarkable increase brought about by steam transportation. Selecting twelve characteristic ports, and commencing with 1832, when steam navigation was practically not in existence, we have the following:

1832,	total tonnage of arrivals	4,832,828
1887,	" " "	54,879,222
1895,	" " "	68,965,483

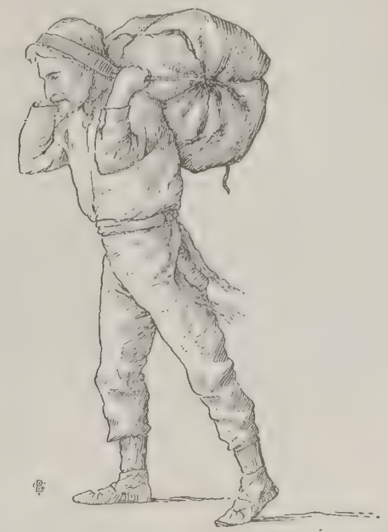
The draft, or depth, of vessels is now restricted by the depth and width of channels in harbor entrances and through outlying bars, or river channels, leading to basins and docks. The author says that if these dimensions are not increased the size of steamships will not much further increase; and in such case the limit of the carrying power and economies of commerce is in sight. Further, and according to Dr. Francis Elgar, the designer of the "Campania" and "Lucania," if the draft of the ship were not restricted, the form of section in the hull could be improved by giving it more rise of bilge and an easier curvature. And as the displacement is increased by increase of draft, the power required to drive a ton of displacement at a given speed is reduced. Hence, increase of draft does not mean a proportionate increase in engine power, even when such increase is obtained merely by extra immersion without any improvement in form, such as would otherwise be possible. The advantages of increased draft would be felt more in a seaway than in smooth water, as the lower part of the hull would be less affected by the wave surface, and better and more constant immersion could be given to the propellers.



4.—Bring the remaining part of the ends of the tie-straps across and around the bundle; then take hold of the head-strap at either end and lift.

The engineer must here assist the naval architect in any further development in maritime transportation. All that the employers of engineers have thus far felt justified in doing or expending the engineer has done or is doing. But it is safe to say that, in the near future, no port in the world will be classed as a first-class port which will not readily admit vessels drawing 30 ft. of water. This means 35 ft. in the entrance channels through sea-bars; 32 ft. in river channels and other entrance approaches, and 31 ft. in harbors and basins, and alongside docks and wharves.

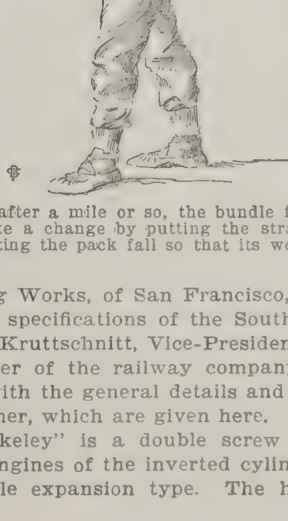
As to what is being done to secure this depth we have the Suez Canal, the key to the harbors of Europe and Asia, built with a depth of 26 ft., deepened to 28½ ft., and planned for 30 ft. The Amsterdam Canal has been deepened from 23 to 30 ft.; the new Kaiser Wilhelm Canal has about 30 ft.; the Liverpool channel has 30 ft. at low tide, or a channel entrance depth of from 27 to 57 ft., according to tide; Southampton has 30 ft., and New York will soon have 35 ft. at low tide; Boston and Philadelphia will have 30 ft. New Orleans is asking for a least depth of 35 ft. over the bar and 32 ft. in the South-West Pass and the River; Galveston, under present plans, will have 30 ft.; Antwerp has a sea-entrance of 30 ft., a river depth of 31 ft. at high water, and a projected port depth of 32½ ft.; Hamburg, in the near future, will have a deep channelway to the sea adequate for the largest vessels.



5.—Throw the pack over the head onto the shoulders; settle the head into the head-strap, easing the backward pull by grasping the strap with the hands; then off you go.

THE NEW DOUBLE SCREW FERRY STEAMER "BERKELEY," OF THE SOUTHERN PACIFIC CO.

One of the largest ferry steamers which we now recall has just been put in service by the Southern Pacific Co. on its San Francisco Bay ferry line between the foot of Market St., San Francisco, Cal., and Oakland Pier. This vessel has been named the "Berkeley," for the city of Berkeley, Cal., located on the eastern side of San Francisco Bay, and the seat of the University of California. It was designed and built by the Union Iron & Shipbuilding Works, of San Francisco, Cal., after the general specifications of the Southern Pacific Co. Mr. J. Kruttschnitt, Vice-President and General Manager of the railway company, has furnished us with the general details and dimensions of the steamer, which are given here.



6.—And if, after a mile or so, the bundle feels irksome, you may make a change by putting the strap across the chest and letting the pack fall so that its weight rests on the ribs.

The "Berkeley" is a double screw steel boat, driven by engines of the inverted cylinder, direct-acting, triple expansion type. The hull is constructed entirely of steel, and has, including the bulkheads at the ends of the screw shaft, seven complete steel bulkheads without openings below the main deck, and two bulkheads with small openings for the transfer of coal from the bunkers to the boiler room. Between these bulkheads are located the crew's quarters, engine room, boiler room, restaurant, wine room, and toilet room. Access to these various compartments is had only from the main deck, making the boats safe against sinking in case of damage to the hull.

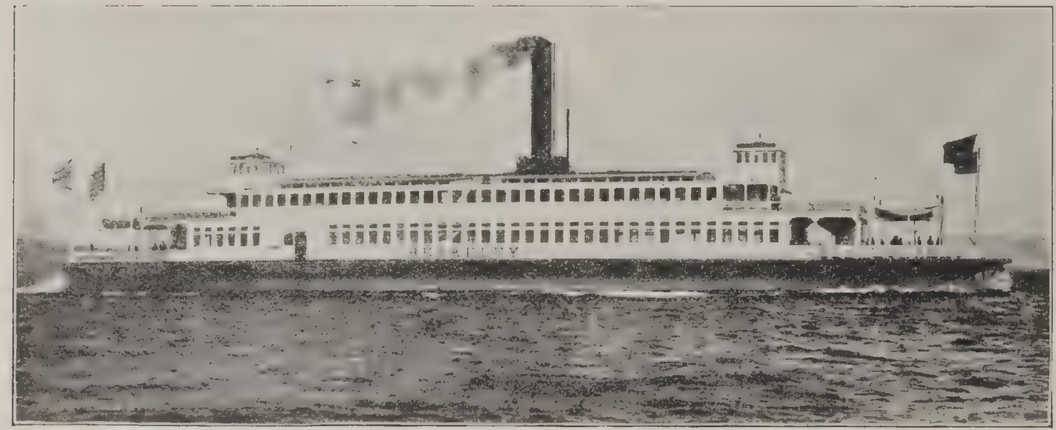


FIG. 1.—THE NEW SCREW FERRY STEAMER "BERKELEY" OF THE SOUTHERN PACIFIC CO.
The Union Iron & Shipbuilding Works, San Francisco, Cal., Builders.

The main deck has a seating capacity of 580 passengers; a toilet room, reached by a stairway from the saloon deck, and two driveways for baggage and for mail and express trucks and wagons. A single stairway at each end of the boat connects the main and saloon decks. The saloon deck has a seating capacity for 997 passengers in the cabin, and for 132 outside, making the total seating capacity of the boat, 1,709 passengers.

The cabin seats are constructed of perforated black walnut on teak wood frames. The floor covering is interlocked rubber tiling. The cabin is painted dead white with gold leaf ornamentation. The clear-story is glazed with art glass. Ventilation and heating is provided for by the plenum process, pipes being provided for the inlet of fresh air and the efflux of vitiated air. The boat is lighted throughout by electricity.

The rudders of the boat are operated by a steam steering gear. A special feature of this boat is its numerous large windows, glazed with plate glass, and set at such a height from the decks that an unobstructed view of the bay of San Francisco can be had from all the seats. Under ordinary running conditions, the trip between San Francisco and Oakland Pier, 4½ miles, is made in 17½ minutes. The principal dimensions and details of the vessel and machinery are as follows:

Length over all	289 ft.
Length inside rudder posts	260 "
Beam, molded	40 "
Beam over wood guard	64 "
Depth molded at guard	16 ft. ' ins.
Depth molded at center	17 " 0 "
Depth of hold	14 " 10 "
Draft, extreme load	8 " 6 "
No. of propellers	Two—one at each end.
Diameter of propellers	8 ft.
Revolutions per minute	125
Registered tonnage, gross	1,945 tons.
Registered tonnage, net	1,245 "
Type of boilers	"Scotch."
Horse-power	1,450
Boiler pressure	165 lbs.
Cylinder diameters	23, 34 and 56 ins.
Stroke	36 ins.

Second story landings are provided and used at both the San Francisco and the Oakland Pier depots, a large proportion of the passengers being thus handled to and from the depots on the saloon deck level. Referring to the illustrations, Fig. 1 is a general view of the vessel; Fig. 2 is a view on the saloon deck, showing the arrangement of the seats and the appearance of the interior finish and decorations; Fig. 3 gives half transverse sections of the steamer through the engine room and boiler room, and Fig. 4 is a plan of the hull.

NOTES FROM RECENT REPORTS OF CITY ENGINEERS AND OTHER MUNICIPAL OFFICERS.

Repairs to macadam streets in Boston, according to the last report of Mr. Benj. Wells, Superintendent of Streets, are successfully and economically made by first picking up the surface with spikes attached to the wheels of steam rollers, then giving the street a light dressing of stone and rolling it.

The Ferry Division of the Street Department has installed electric motors for assisting teams on and off the boats at extreme stages of tide. The running time of the boats has been improved by the installation.

Concrete gutters in place of macadam have been found necessary on the Commonwealth Ave. Boulevard, in Newton, Mass. Such gutters were included in the original estimates, but as the work progressed it was thought that they could be dispensed with. It was found that the combination of frost and moisture was causing the disintegration of the macadam, and that wheel ruts were cutting down to the foundation. Contracts were let in 1897 for putting in 3-ft. gutters on all the steeper grades. Mr. H. D. Woods, M. Am. Soc. C. E., is City Engineer of Newton. Mr. Wood's report for 1897 contains a review of work done during the year in the abolition of grade crossings, illustrated by numerous reproductions of photographs.

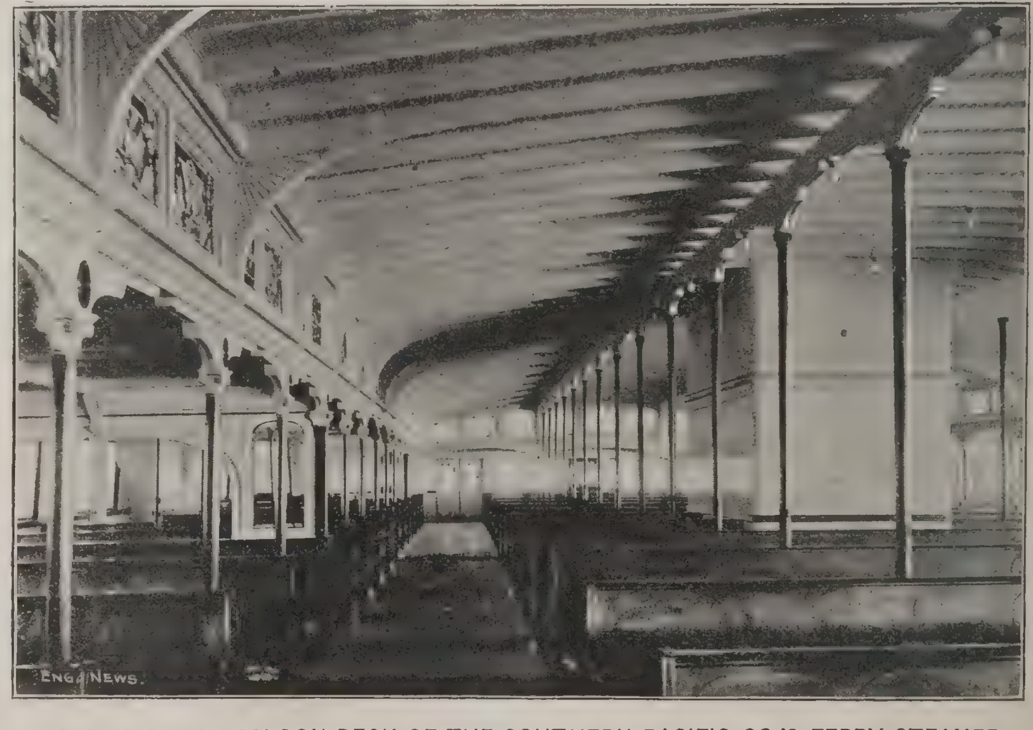

FIG. 2.—VIEW ON SALOON DECK OF THE SOUTHERN PACIFIC CO.'S FERRY STEAMER "BERKELEY."

A special feature of the last report of Mr. E. A. Fisher, M. Am. Soc. C. E., City Engineer of Rochester, N. Y., is a table showing the cost of asphalt paving in a number of cities when reduced to a proper basis of comparison with Rochester, ordinary excavation and a 6-in. concrete foundation. The consecutive columns in the table are as follows: Name of city; year of return; reported price; percentage of correction; corrected price, for 5, 10 and 15-year guarantees; security required; cash reserve and bond; kind of asphalt laid; amount laid, and remarks. Mr. Fisher took his original figures from replies to a circular sent out by himself, from a report by Mr. F. W. Capellen, City Engineer of Minneapolis, and from notes made while on tours of inspection to other cities. These figures should be suggestive to those city officials who are met with wild statements regarding the low comparative cost of paving in other cities, without regard to the relative character of the work and local conditions.

A report on the apportionment of the cost of a proposed joint outlet sewer for a small section of Newark and a number of adjoining or near-by communities, has recently been made by Mr. Alex. Potter, Assoc. M. Am. Soc. C. E., of New York city. Mr. Potter reviews at some length the methods employed heretofore in the distribution of the cost of joint municipal works, and finally recommends a plan summarized by him as follows:

> The apportionment recommended will be based upon the amount of sewage contributed by the possible ultimate population of each district or municipality, determined by a detailed examination of the physical characteristics and environments of the various municipalities, and a study of the water supply of each.
>
> Further, that the absolute right shall be granted each municipality or district to own, control and dispose of so much of the cubical capacity of the outlet sewer as is proportionate to the percentage of the total cost of the joint outlet which is borne by each municipality or district.

Unfortunately, so limited a number of copies of this report were printed as to make their distribution, on application, impossible.

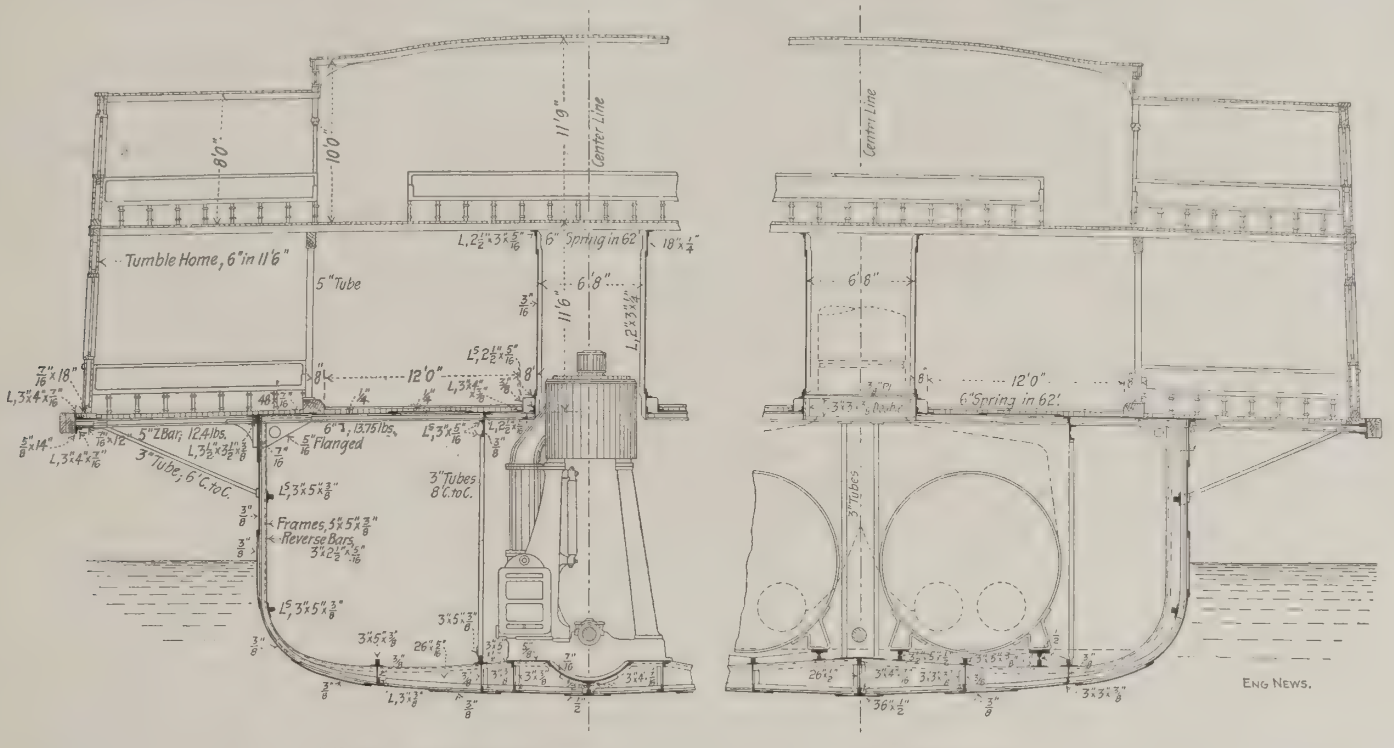
Heavy rainfalls in Philadelphia are cited in the last report of Mr. Geo. S. Webster, M. Am. Soc. C. E., Chief of the Bureau of Surveys, as follows:

> June 8 to 9, in 21 hours, 2¼ ins.; July 19 to 23, 5 ins. On Aug. 19, 1.34 ins. fell in 3½ hours. The greatest intensity of rainfall occurred Oct 12, when for a space of five minutes the precipitation was at the rate of 2¾ ins. per hour. Aug. 23, for 15 minutes the rate was 2½ ins. per hour. At that time the water in the sewer (6 ft. in diameter) on Lombard St. near Third St., rose 4¾ ft.

The effect of the best material and workmanship upon the carrying capacity of pipe sewers is well illustrated by the extract given below, from the last report of Mr. T. Chalkley Hatton, M. Am. Soc. C. E., Engineer in Charge of Sewers, at Wilmington, Del. The sewer in question is for foul liquid wastes, only, and serves an area of 931 acres, and a population of about 46,500 people. The sewer, and tests of it, are described by Mr. Hatton as follows:

> The total length of this sewer is 15,102 ft., and its mean average fall is 5.75 ft. in 1,000 ft. It is composed of 3,-

091 ft. of 18-in. terra cotta pipe, standard thickness, on a grade of 6.5 ft. per 1,000 ft.; 2,106 ft. of 20-in. terra cotta pipe, double strength, on a grade of 6 ft. per 1,000 ft.; 6,952 ft. of 24-in. terra cotta pipe, double strength, on a grade of 8 ft. per 1,000 ft.; and 2,953 ft. of brick and concrete sewer, from 2½ × 3¾ ft. to 5 ft. in diameter, on a grade of 2 ft. per 1,000 ft. Its total cost has been $43,546. This includes the amount paid the contractor, inspectors' salaries, costs for right of way, incidentals and office expenses. Three per cent of this cost was paid for inspection, and when you consider the nature of the work this percentage is very small.



Half Section through Engine Room. Half Section through Boiler Room.

FIG. 3.—TRANSVERSE SECTIONS THROUGH ENGINE AND BOILER ROOMS OF THE FERRY STEAMER "BERKELEY."

Owing to the nature of the fluids which have to be carried through this sewer (they being the thick liquid wastes from a morocco shop principally, of which a large percentage consists of hair, lime, scraps of skins and other heavy matters), and because but a small portion of the capacity of the sewer would be needed for many years, I was particularly concerned for its ability to keep itself clean, and to overcome the liability of stoppage as far as possible, the specifications for the pipe, and the laying thereof, were made particularly stringent; we insisted upon having the best pipe in the market, paying particular attention to having them so laid that the flow line of the pipe should not be interrupted at each joint by one pipe being a little bit higher or lower than its neighbor. We used hemp in the joints for this purpose, and succeeded in getting an uninterrupted flow throughout, although the 18-in. and 20-in. pipes were not as uniform either in diameter or in circular shape as could have been desired, but were the best we could get, and I desire to here call your attention to the effect upon the capacity of this sewer resulting from this very close inspection; as soon as the sewer was finished and examined, I made a test of its carrying capacity, having a chance to turn into its upper end whatever flow of water I desired for this purpose. We procured eight cork floats, varying in size from 3½ ins. in diameter to 3 ins. by 6 ins. long, and 1-in. thick, there being four different sizes and shapes, one of which was loaded sufficiently to guarantee its being constantly submerged, and its mate being light so that it would float upon the top of the water. With the help of three men and a stop watch I found the velocity of the water running in the 18-, 20- and 24-in. pipes. Averaging the velocity of the eight floats, (although I found but little difference between the velocity of any of them, the loaded ones travelling as fast as the light ones), the result was that the velocity in the 18-in. pipe was found to be 5.75 ft. per sec., the coefficient of friction .011, making its capacity 10 cu. ft. per sec., whereas the calculated velocity before it was built, was to be 4 ft. per sec., its coefficient of friction .015, and its capacity 7 cu. ft. per sec. The velocity in the 20-in. pipe was found to be 6.8 ft. per sec., its coefficient of friction .01, and its capacity 14.8 cu. ft. per sec., whereas the calculated velocity was to be 4.14 ft. per sec., the coefficient of friction .015, and its capacity 9 cu. ft. per sec. The velocity in the 24-in. pipe was found to be 12.47 ft. per sec., its coefficient of friction .0075, and its capacity 39 cu. ft. per sec., while its calculated velocity was to be 5.47 ft. per sec., its coefficient of friction .015, and its capacity 17 cu. ft. per sec.

An ideal park system for a large city, according to a statement by Mr. John. C. Olmstead, in a report to the Board of Public Works, of Indianapolis, should include the following: (1) A central tract for public buildings; (2) a series of small parks; (3) a series of local parks of greater extent than (2); (4) one or more large parks in the outskirts, where one may drive for an hour or two without going over the same roads twice; one or more great reservations, thousands of acres in extent; and (6) parkways connecting two or more of the parks. Mr. J. Clyde Power is Engineer and Superintendent of the Park System of Indianapolis, and has issued a pleasing illustrated report for the year 1897.

The last report of the Board of Public Works, of Detroit, Mich., contains the results of tests of 5,296 gas meters, new and repaired. Of 2,780 new meters, eight were condemned for registering too fast, 4.22% on the average, and four for registering too slow, averaging 4.67%, and four were condemned for other reasons. Of 2,439 repaired meters, 63 were condemned for registering too fast, 3.98% average, and 22 for being too slow, 5.27%; 14 were condemned for failing to pass gas, not registering, leaking and other causes. Mr. Robt. Y. Ogg is Secretary of the Board, and Mr. Henry D. Ludden is City Engineer.

A variety of interesting and useful information regarding the streets of St. Louis has been made public by Mr. A. N. Milner, Street Commissioner, in a pamphlet prepared for general distribution. Statistics, extracts from paving specifications, and numerous illustrations are included.

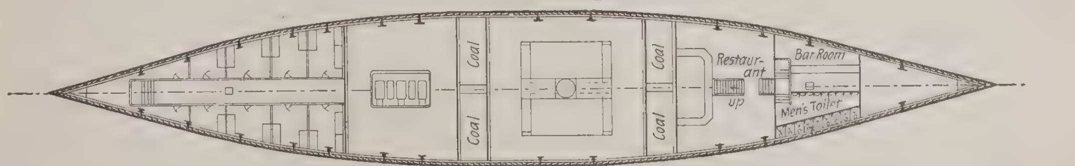


FIG. 4.—PLAN OF HULL OF FERRY STEAMER "BERKELEY," SHOWING BULKHEAD ARRANGEMENT.

The last report of Mr. E. J. Barrow, City Engineer of Hamilton, Ont., contains a brief description of a new sewage disposal plant, the second one built by the city. Chemical precipitation is used at each plant. The plants are located in different parts of the city. A plan and sections of each plant are given in the report. The first plant built was described in Engineering News for Jan. 28, 1897.

PROSPECTS OF THE KLONDIKE MINING REGION.

An interesting story of the "boom" in the Klondike mining region is told in a paper by Mr. Samuel C. Dunham, in the "Bulletin of the Department of Labor," for November, entitled "The Alaskan Gold Fields, and the Opportunities they offer for Capital and Labor." Mr. Dunham is an agent of the Department, who made an investigation on the ground from Jan. 8, to Aug 1, 1898. We advise any one who thinks of going to the Klondike, or of investing in any of its properties, to obtain a copy of the "Bulletin" and study Mr. Dunham's paper before concluding the arrangements. We quote the following summary:

> The Klondike stampede was unique, and it may be interesting to survey the situation briefly with particular reference to its most fascinating feature, the financial result. It is a common assumption among those familiar with the uncertainties of mining for the precious metals, that every dollar's worth of gold extracted from the earth costs somebody at least a dollar in money or labor. Applied to the case under consideration, this assumption is far within the bounds of truth. By actual count, 40,000 men started for and reached the Yukon gold fields during the year beginning with July 15, 1897. It is conservatively estimated that 20,000 more undertook the journey, but were unsuccessful in their efforts to reach the Yukon. It is fair to assume that the average expenditure of these 60,000 men, for outfitting and transportation was $500 each, or a total expenditure of $30,000,000. It is probable that the money invested in ocean and river vessels and the organization of commercial companies for operations on the Yukon would add $5,000,000 to this sum. Without considering the large amounts that have been absorbed in the capitalization of Klondike mining companies, a few legitimate and many wildcat, it may safely be assumed that this great movement during the year following its inception cost the participants $35,000,000, and it is equally safe to assume that in the case of 75% of the individuals involved, their contributions are an absolute loss to them. As against this enormous outlay, we have for the period under consideration, as indicated by the mint returns, a gross product from the Yukon placers of less than $12,000,000.
>
> Although this statement as to the immediate result of the Klondike "boom" cannot be refuted, it would be misleading if allowed to stand without qualification. The condition described is almost entirely due to the exaggerated statements as to the extent of the new discovery so widely published in last year's newspapers and magazines, and should not be permitted to obscure the fact that there is now being developed on the Yukon a mineral zone of wonderful richness, which will eventually contribute hundreds of millions of dollars to the wealth of the world. The lesson to be learned from the present situation is that it will take years of hard work to bring the mines up to their highest point of productiveness, and that the country offers no opportunities for professional men or others who are not equipped by nature for the most exacting manual labor.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; *6 months,* $2.50; *2 months,* $1.00. *To all other countries in the Postal-Union: Regular Edition, One Year,* $7.60 *(31 shillings); Thin Paper Edition, One Year,* $6.31 *(26 shillings). SINGLE COPIES of any number in current year,* 15 *cents.*

In ordering changes of mailing addresses, state BOTH old and new addresses; notice of change should reach us by Tuesday to be effective for the issue of the current week. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 329 *means that subscription is paid to the 32d week (that is the issue of Aug.* 10) *of the year* 1899; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want notices, special rates see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

A new plan for the maintenance of railway rates has been brought forward by the Receivers of the Baltimore & Ohio R. R. They have forwarded a letter to the Interstate Commerce Commission, in which they declare at the outset that:

> Within the territory north of the Ohio River and east of the Mississippi, the railroad carriers are transporting the larger part of the interstate traffic at rates less than those shown on the published tariffs, filed with your Commission, which are by statute the only lawful rates.

This being the state of affairs, and the voluntary association of railway companies to discover and check discrimination and secret cutting of rates having been declared illegal by the Supreme Court, the Baltimore & Ohio Co. now proposes to appeal to the Interstate Commerce Commission. Beginning on Jan. 1, it will maintain on all its lines the rates for passenger and freight traffic shown on the published tariffs filed with the Commission, and it announces that if any of its competitors depart from their published tariffs, the aid of the Commission will be invoked to stop them.

The working of this new plan for the maintenance of rates will be watched with much interest. Messrs. Cowen and Murray, the Receivers of the Baltimore & Ohio, express the belief that all or nearly all of the railways will follow the B. & O.'s example and begin to maintain strictly the published tariff rate on Jan. 1. It may be of interest to note that by the terms of the Interstate Commerce Law, the charging of a rate different from the published rate is made a misdemeanor, punishable by a fine not to exceed $1,000.

◆

The use of steel for large pipe lines is now becoming so common as to attract comparatively little attention, unless some departure is made from the usual type of construction, or the size or length of pipe is something unusual. The contract for the Coolgardie pipe line, the details of which are given elsewhere in this issue, is notable for both the mode of jointing the pipe and the size of the contract. The line will be 30 ins. in diameter and 328 miles long, but will be practically rivetless. Each section of pipe will be 28 ft. in length, made from two plates, each bent to a half circle and joined by two horizontal locking-bars, each plate edge being dovetailed into one side of a bar and secured there, watertight, by hydraulic pressure, as described in our issue of June 9, 1898. The ends of the 28-ft. sections will be fitted together and the joints formed by an overlapping steel ring, or sleeve, calked with lead. It seems probable that some other type of transverse joints may be used in some cases, whether at regular intervals or under special local conditions we cannot say. Nearly all the pipe will be made from ¼-in. steel plates, less than 2 per cent. in length, being from 5-16-in. plates. The pipe line, as contracted for, differs materially from the recommendations of the advisory English engineers, discussed at length in our issues of Feb. 17 and Oct. 13, 1898. This is largely due to the low bids received on the style of pipe adopted. The English engineers advised the use of 26, 27½ and 29-in. pipe, according to the head, or velocity; that pipe with gas-welded longitudinal joints be used for all pipe ¼-in. thick or over, and that the pipe be laid above ground, on account of the probable action of the salts in the soil on buried pipe. The last recommendation made necessary expansion joints, the design of which we described and adversely criticised in our issue of Oct. 13. Bids, therefore, were invited on 82 miles of welded and 246 miles of riveted pipe, with the results stated elsewhere in this issue. One bidder offered to substitute locking-bar pipe for the welded pipe at such low figures that negotiations were entered upon, which resulted in the adoption of this style of pipe throughout, increased to a uniform diameter of 30 ins., and with ¼-in. plates substituted for the large quantity of 3-16 plates. The changes in size and thickness were effected at an advance of only about $100,000 in the total cost of the pipe, thus reducing the pump friction and adding to the permanency of the line. The adoption of transverse joints, that can be calked with lead, and the placing of the pipe underground "in most cases," will effect a considerable saving in cost. Getting the pipe below ground, and doing away with the expansion joints recommended by the English engineers are changes greatly for the better, we believe. In fact, if the locking-bar and ring joints prove satisfactory, we think Mr. O'Connor will deserve the highest praise for the changes he has made from the design recommended by the engineers. He has done away with all rivets and with changes in the diameter of the pipe every 28 ft., which would have been caused by placing the sections alternately inside and outside of each other. This, coupled with the increase in size, ought to decrease the friction materially, and thus reduce the pumping expenses. When it becomes desirable to sacrifice friction for an increase in capacity, through enlarged demands for water, this can be done, thus delaying the necessity for constructing a temporary pipe line. In our issue of Feb. 17 we stated that it would be foolish to employ an untried invention, like this locking-bar joint, on a piece of work of such magnitude. But since then, as we have already stated, it has been used at Adelaide on 8¾ miles of 26-in. steel pipe, and, we are informed, with entire success. The merits of the device are certainly worth consideration by American engineers and contractors interested in steel pipe manufacture and use.

◆

The condition and prospects of the water-works of Philadelphia are becoming more and more alarming. Urgent improvements are postponed from year to year. Little or nothing is being done to provide for future needs. Portions of the existing works are improperly cared for, some of the costly pumping plant being housed under a temporary board shelter. Nothing is being done to check the rapidly increasing waste of water, although the per capita consumption has reached an enormous figure. The character of the water is notoriously bad, and has been for years, yet practically nothing is done to improve it. The works are being slowly wrecked by the refusal of appropriations for their maintenance and improvement. The executive branch of the city government has pointed out the needs of the water department time and again, and pleaded for appropriations. But it is all of no avail. Just now some of the councilmen are making a great show of virtue and indignation. We believe most emphatically, they assert, in municipal control of the water-works, but if the administrative branch of the city government cannot give us a definite plan for pure water we shall be compelled to contract with some private concern that has the ability to formulate such a plan. This sounds well, but it is very misleading. The department of public works, and the bureau of water, have repeatedly asked for appropriations to make investigations of water purification, but have never received a cent. Had such appropriations been granted, when first asked, several years ago, not only plans, but purification works, might now be ready. The appropriations having been denied, the water department has been helpless during the months and years of agitation, giving ample opportunity for promoters to work out detailed plans meanwhile. To a city councilman who seldom or never drinks water and who cares infinitely more for the success of his party and the length of his purse than for the health or interests of his constituents, it may seem a light task to prepare plans for the purification of 200,000,000 to 300,000,000 gallons of water per day, but to any other mortal the problem becomes a serious one the moment he begins to give it practical consideration. The cities of Providence, Louisville, Pittsburg and Cincinnati have not hesitated to spend months of time and thousands of dollars in studying the problem of purifying much smaller quantities of water, and had Philadelphia taken up the study at the same time, with the same civic and scientific spirit, it might have solved it or been near a solution ere this.

◆

That Chicago, of all places in the world, should be afflicted with a plague of snails must be set down as one of the most remarkable occurrences of the year 1898. According to a report submitted to City Engineer Ericson by Prof. Frank C. Baker, snails have appeared in large quantities in the Lake View water supply, and their eggs are found in great numbers upon the screens at the opening of the Lake crib. The prospect that the mollusks will accumulate in the tunnels and finally die and contaminate the water is now causing no small anxiety to those responsible for the city's water supply.

Just why the peaceful snail should choose the floating anchor ice around the Chicago intake cribs as a place in which to display its reproductive powers, must be counted as one of the unsolved problems of biology. Its natural habitat would seem to be the water supply of Philadelphia; but in recent years that has become too bad for even snails to endure.

A FEASIBLE PLAN FOR THE NEW YORK RAPID TRANSIT RY,

For more than a dozen years has the project for an underground rapid transit railway up and down Manhattan Island, to be constructed with the aid of the city's credit, been before the public. At various times the construction of the road has seemed practically assured; but some obstacle has always intervened to prevent the actual undertaking of the work. The attitude of this journal toward the enterprise has been uniformly one of friendship. We have held from the outset that hardly a great engineering project of the century offers so sure a financial success as the project to convey passengers up and down the length of Manhattan Island, through the central part of the most densely populated city in the world, with a saving of half or more of the time required for the journey.

But while we have recognized the great merit of the scheme as an engineering and financial proposition, we have also been well aware of the difficulties which have hedged it about. The existing Rapid Transit law is a hodge-podge of contradictions. It prescribes a financial scheme for the construction of the road complicated enough to prevent any responsible contractor from ever undertaking the work, and it surrounds the whole enterprise with restrictions and red tape enough to seal the doom of the most promising project that was ever planned.

We have consistently favored the policy of municipal ownership and control, and in some cases of municipal construction of street railway lines. All this has been done, and done successfully; but such a hybrid alliance between city and a corporation as the New York Rapid Transit act proposes was never known on earth. We believe, therefore, that the first step toward the construction of the New York Rapid Transit railway, is not the amendment, but the repeal in toto of the present Rapid Transit act.

Before outlining what should be put in its place, let us discuss briefly certain engineering aspects of the enterprise. The most important feature of the New York Rapid Transit scheme is the provision of a four-track road with two tracks for express trains, stopping only at stations two or three miles apart, and the other two for local trains, stopping at stations ¼ mile or so apart. It is proposed that the local trains shall collect passengers at express stations, and distribute them from these stations. We believe that for the peculiar local conditions on Manhattan Island (enormously heavy traffic concentrated in a single direction), this scheme promises great benefits to the public in the saving of time. We are aware that it has been criticised, and that some have attempted to show that the time saving would be little or nothing over the time of transit by the present elevated railways in the case of a passenger who has to take first a local train, then an express train, and then a second local train to reach his destination. If it were proposed to operate the Rapid Transit road by steam locomotives with such train intervals as are common on the present elevated railway lines, this criticism would have considerable weight. But nobody proposes, or has proposed for many years, to operate the road in that way. With electric motor cars, on both the local and express tracks, having power enough to make a quick start, and running at as short intervals as safety permits, it would be feasible to make a very great time saving, in the journey from New York's business district to its residence district, even when two transfers have to be made.

The original $50,000,000 plan of the Rapid Transit Commission comprehended a four-track road from the Battery up Broadway to the northern limits of the city, with various four-track and two-track branches, which we need not now describe. In the modified plan of the commission, contemplating an expenditure about two-thirds as great, the four-track scheme was still adhered to.

The matter to which we wish to call especial attention, is that while the four-track scheme was an excellent and proper one when it was planned, the march of events has now rendered it obsolete, and it is no longer the best or wisest plan of furnishing real rapid transit for New York city. When the Rapid Transit scheme was originally planned, the surface street railways of New York were operated by horses, or in a few instances by cable traction. The coming year will see practically all the main north and south surface lines operated by electricity, and in a manner which leaves little to criticise. In other words: The local tracks for the New York Rapid Transit Ry. have been laid and are now in operation on the surface of the streets.

If the local lines of the proposed Rapid Transit railway were now completed and in operation, they would be forsaken by travelers for the electric cars on the street surface. Passengers will not walk even a block or two and descend to an underground station when they can take an electric car on one of the surface roads at the nearest corner. Further, the rate of speed, including stops, attained on the present electric conduit roads is nearly or quite as good as what the proposed local trains of the New York Rapid Transit Ry. could make.

If these facts are fully understood, it will be at once seen that all that is required for the carrying out of the New York Rapid Transit enterprise, with practically the same measure of public benefit as originally proposed, is to build two-track tunnel roads, for express trains only, beneath some of the principal north and south lines of the present electric conduit system.

Such a two-track tunnel could be built without any difficulties from the destruction of vaults, the interference with building foundations, and the closing to traffic of the entire street that arrayed so many interests against the original Rapid Transit enterprise. Its cost, moreover, would be comparatively very moderate, and it could be built and operated in sections and extended as fast as its success was demonstrated and the public demand warranted.

Of course these proposed express tracks would need to be operated in entire harmony with the present surface railways, and this means practically that they must be built and operated by an arrangement between the city authorities and the Metropolitan Street Railway Co. Such an arrangement, if we may trust the evidence of recent outpourings from the oracle that rules our destinies, is already "in the air," and the coming year may very likely see it placed on a firm basis of fact.

It may be objected that such a plan of construction will not afford the same measure of benefit to the city treasury as would have accrued from the original plan under which the road was to be owned by the city and leased for operation to a corporation. This is doubtless true, provided the original plan of construction could have been carried out, and provided also that conditions had remained the same that they were when it was planned; but it is quite within the possibilities that they would not have remained the same. Had the city undertook the construction of the Rapid Transit system eight years ago, as it came so near doing, it is quite possible that the diversion of traffic which would have ensued when the surface roads adopted electricity might have made the enterprise a financial failure.

Past conditions are past, however, and the conditions which at present confronts the city are these: Should it obtain legislation enabling it to build the four-track Rapid Transit system as originally planned, it is extremely doubtful whether the local lines could obtain sufficient traffic to pay for their operation with the frequent trains and short train intervals which are essential to the system's usefulness. It is evident that the four-track Rapid Transit system, as originally proposed, would never prove profitable from its express train traffic alone. The long distance traffic must be handled in connection with the short distance traffic to make it profitable. Again, should the city adopt the plan we have proposed above and construct a system of double-track tunnels for express train service only, it must operate them in connection with the surface electric roads, and probably a system of transfers between the surface and underground lines would be a necessity to secure a paying traffic.

The whole matter, then, resolves itself into this: The city has one chance, and one only, of securing the system of combined local and express transit up and down Manhattan Island which is so urgently needed. That chance is an arrangement with the Metropolitan Street Railway Co. for the construction and operation of a system of double-track express-train tunnels beneath some of its principal north and south lines.

That such an arrangement could be devised which would promise great benefits to the city, and would at the same time offer great attractions to the railway corporation there is every reason to believe. Whether the Rapid Transit Commission, the present city authorities, the powers behind them, the new state government, and the groups of financiers who control the Metropolitan Street Railway Co. can all be brought into agreement upon such an arrangement, is another and far different question which we shall not attempt to answer.

As we have said above, however, in such a co-operation between the city and this corporation lies the only real hope for the Rapid Transit enterprise. Besides the reasons for this that we have already set forth, there are others of equal or greater force. As everyone knows, the proposition to carry out the enterprise on its original lines, with the aid of the city's credit, has enlisted against it both the present city government, and the political leaders whose word will exercise great influence in shaping legislation at Albany. Besides this, the real estate owners of the city look askance upon the proposition that under a separate county organization further bonds in unlimited amount can be saddled upon the real estate comprised in the Boroughs of Manhattan and the Bronx.

All these facts in connection with a real change in public sentiment toward the Rapid Transit enterprise make the proposition to revive it, on its original lines, a scheme that can be called little less than Quixotic.

On the other hand, the need for real Rapid Transit up and down Manhattan Island grows every year with the growth of that section of the city north of Central Park, and that other and much larger section north of the Harlem River. The speed of the Manhattan elevated trans is 12 to 14 miles an hour, including stops. The electric conduit cars, where streets are not too crowded, make 8 to 10 miles per hour, including stops. These speeds are all right for short trips; but for long journeys they are far too time-consuming to satisfy the reasonable demands of modern life. Let us for a moment see what saving of time would be possible through such an express tunnel system as we have outlined, with stations, let us say, at City Hall, 23d St., 59th St., 90th St., 125th St. and the Harlem River. Let us assume a maximum speed of 40 miles per hour for express trains, and also that stops are made on the average in a distance of 700 ft., and in 30 seconds' time; also that a distance of 1,500 ft. and 50 seconds of time are required for the train to attain full speed; also that an average of 25 seconds is spent at each station in receiving and discharging passengers. The time of express trains from the City Hall to the Harlem River, about nine miles, would then be as follows:

	Seconds.
Stops at 4 stations (25 secs. at each)	100
Getting under way 5 times (50 secs. each)	250
Slowing up 5 times (30 secs. each)	150
Deduct distance run in getting under way (7,500 ft.) and in stopping (3,500 ft.), from total distance leaves 7 miles run at full speed; time to run 7 miles at 40 miles per hour	630
	1,130

Total time, City Hall to Harlem River. . 18 mins. 50 secs.

These assumptions of times and distances of acceleration and retardation are made after comparison with the results of actual tests, and it is worth noting that they by no means represent the limit of what is practicable. By arranging the station levels on summits with a sharp descending grade on either side, the time spent in getting up speed and in stopping the train can be considerably reduced, thus permitting either a reduction of the time between terminals or an increase in the number of stations. The stations, however, should not be placed much closer together than is indicated in the above, except, perhaps, toward the terminals at either end of the line. The surface roads should be left to collect at and distribute the passengers from the express stations. Taking average speeds of the electric surface cars at a mile in 8 minutes, and allowing 2 minutes' average wait for an express train, it will be seen that a passenger could ride half a mile to the City Hall express station, take an express train to 125th St., and then take another half-mile ride on an electric car to his destination, all in about 26 minutes.

Of course the above suggestions for the location of stations are merely tentative. We have merely assumed them to make plain that by such a combined local and express service as the new electric conduit railways make practicable, a great saving can be made in the time required for daily travel in this busy city. The benefits of such a time-saving to the city and all its people can hardly be overestimated. It is greatly to be hoped that the Rapid Transit Commission may be able to bring about some arrangement between the Municipality and the Metropolitan Traction Co., by which this improvement may be brought to pass.

LETTERS TO THE EDITOR.

One-Story Buildings with Saw-Tooth Skylights for Weaving Mills.

Sir: I have noticed with some curiosity the recent discussion in your journal about the one-story factory at Hammond, Ind. (Engineering News, Dec. 8, 1898), because it seems to have been considered as a novelty in factory construction. As a matter of fact, there have been no less than six buildings of this type, with large "saw-tooth" skylights, built in the Eastern States from designs made by me within the past three years, one of them covering over two acres in one room. I would not express any opinion as to the merits of this construction for the purposes of the printing company referred to in your articles, as I think a building should always be designed with especial reference to the use to which it is to be put, but for the purposes of weaving, for which all of the buildings designed by me were intended, there is nothing that can equal it. It is an ideal construction for this purpose. I believe I was the first to adopt it to any extent, in the form I have designed, with the very large glass surface, and adapted to New England climatic conditions. The objections you speak of, on the score of fire risk, were fully considered, and, while there is some force in them, they were insignificant in comparison with the great advantage gained, by obtaining a perfect and uniform light, which is the paramount desideratum for weaving.

Yours truly, F. P. Sheldon.

Providence, R. I., Dec. 10, 1898.

Do They Get Their Engineering Work for Nothing?

Sir: A town in the Middle West, having a population of about 4,500, desires to put in a first-class municipal water-works plant. The mayor invites engineers to submit prices for making plans and specifications for the proposed plant. After receiving bids for performing the engineering services, the town council decides that better and more economical results can be obtained by asking contractors and builders to furnish their own plans and specifications and estimates of cost. It would be interesting to hear from any one knowing the actual experience and results of other towns proceeding in a similar manner.

An Engineer.

Kansas City, Mo., Dec. 21, 1898.

[In asking for bids for a bridge, or a pumping engine, or any piece of machinery whose design can be determined by the manufacturer with comparatively little regard for local conditions, there is much to be said in favor of the plan of permitting the bidder to make his own designs. In constructing a water-works or sewerage plant, on the other hand, it is absolutely necessary that completed surveys be made, before any intelligent design and estimate can be prepared. The town can have one survey made by a competent engineer, and a design made upon that survey; or it can require that every contractor who submits a bid shall go to the expense of making a survey and design on the chance of getting the contract. The latter course will certainly result in crude designs and high bids. Business experience teaches that those who try to get something for nothing generally fail in the attempt. The same rule holds good in the conduct of municipal business.—Ed.]

◆

Concerning Hydraulic Dredging Patents.

Sir: I have just read in Vol. XL. of the Transactions of the American Society of Civil Engineers the very interesting paper presented by J. A. Ockerson at the Annual Convention in July last, entitled "Dredgers and Dredging on the Mississippi."* I cannot spare time to notice this as I would like, but there is one matter in the discussion of this paper upon which, in justice to my licensees, I feel called upon to make brief comment. This would have been done at an earlier date but for the fact that my absence in Europe prevented it from falling under my notice. In Prof. Haupt's discussion of this paper there occurs the following:

> Under the subdivision of water jets., etc., the writer (Mr. Haupt) is impressed with the failure to refer to the pioneer and basic patent for the system of removing spoils from the bed of a river or bay by means of rotary cutters with inward delivery, centrifugal pumps and flexible distributing pipes as issued to Mr. A. B. Bowers, C. E., of San Francisco, and which has been applied so extensively in various modified forms on rivers and harbors, to the great benefit of commerce. The claims of the patentee have been uniformly sustained by the United States Courts, and the inventor's time is consumed in efforts to protect his interests, the history of which reads like a romance. Active opposition to an invention is, however, the best evidence of its merit. These dredges were used at St. Louis, on the Mississippi; on the Chicago drainage canal; at Seattle, Tacoma, Alameda Bay, and, in modified forms, on the Atlantic and Gulf coasts, with great effect.

Now, Mr. Ockerson's connection with the commission for the improvement of the Mississippi River, especially in connection with the references giving in his closing paragraph, are such as to make his statements authoritative. But, in view of my suit against the United States for infringement of my patents, in the use of this apparatus, it could not be expected of Mr. Ockerson to state that under the numerous decisions of the United States Circuit, and Circuit Court of Appeals, much of the more indispensable portions of these machines are covered by the Bowers' patents. On the contrary, I marvel at his furnishing the facts that prove my contention, and had he let the matter rest here, I should have had abundant reason to be grateful for the service rendered. But, replying to Mr. Haupt, he says:

> In reviewing the discussion it may be well to state that the author did not intend to exhaust the subject in the brief space of a single paper, and purposely omitted descriptions of many channel improvement devices that have come to his notice. It may also be well to state that he aimed to limit himself to devices proposed for, or used, on Mississippi River. With these explanations, Professor Haupt will understand why the author failed to "refer to the pioneer and basic patent," etc., and also omitted the mention of many devices, several of which have been described by Professor Haupt.

Now, in the explanation quoted, Mr. Ockerson has, unintentionally, without doubt, done me an injustice. His language is susceptible of the construction that he does not consider any of the devices described in his paper to be covered by the Bowers' patents. This cannot be true, if he has read the decisions to which I have referred, and he will doubtless thank me for correcting any wrong impression that may have been conveyed, inadvertantly, I am sure, in his explanation.

Yours very truly,
A. B. Bowers.

New York, Dec. 24, 1898.

◆

Some Results of a Test of a Hydraulic Cement Containing a Large Percentage of Sulphides.

Sir: Herewith I send you a table of tests made with a certain brand of American cement, the name of which is withheld. The cement was bought on specifications, which required a certain tensile strength after one day in air and six days in water; also a certain fineness on a No. 100 sieve. The samples taken passed the tests given and the cement was accepted. The usual test for change of volume showed no defects, as noted under remarks in the table. The sand tests also were good. The percentages of sulphuric acid and magnesia were thought to be low enough, but the high proportion of sulphides caused the cement to be looked on with suspicion. The cement was therefore used in comparatively unimportant work. Part of the cement so used took a fairly good set, but part of it failed to get hard.

Further tests were then made with the cement. It was found to take a good set in water, but if allowed to dry would lose a great part of its strength, as may be seen from the table. For example, 10 briquettes were put in air one day, then left in water for six days, then removed from the water, and kept in a damp atmosphere at a moderate temperature for seven days more before breaking. These briquettes showed a strength (Table I.) of only 158 lbs. per sq. in.

TABLE I.—Results of Experimental Tests of a Defective Hydraulic Cement.

			Days			Tensile strength,		
No.	Date, 1898.	No. briquettes.	In air.	In water	In air.	Max., lbs.	Min., lbs.	Avg., lbs.
1.	July 27.	..	1	6	0	564	352	443[1]
2.	Aug. 18.	..	1	6	0	232	196	213[2]
3.	Aug. 18.	..	1	27	0	382	300	345[2]
4.	Oct. 3.	10	1	6	0	614	412	496
5.	" 3.	10	7	0	0	240	152	203
6.	" 3.	10	1	1	5	254	184	229
7.	" 3.	10	0	7	0	482	368	451[3]
8.	" 26.	10	1	6	1	286	224	258
9.	" 26.	10	1	6	7	182	136	158

Remarks: [1]Pats O. K. [2]Sand test—1 cement 3 sand—pats O. K. [3]Briquettes swollen slightly.

Note.—Fineness = 94.8% on No. 100 sieve; magnesia, (MgO), = 2.25%; sulphuric acid (SO_3), = trace; sulphur as sulphide (S), = 1.21%. All samples were from the same lot of 120 barrels.

The experiments Nos. 4-7, under date of Oct. 3, were made simultaneously with similar tests of Atlas American Portland and German Puzzolan cement. In these tests with the Atlas cement, the highest result obtained was 854 lbs. after one day in air and six days in water; the lowest was 765 lbs. after seven days in air only. With the Puzzolan, the highest was 455 lbs. after one day in air and six days in water, while the lowest was 435 lbs., after seven days in air only. Each result was the average of ten briquettes. Hence, we may say that the Atlas and Puzzolan cements do not show an important falling off in strength when removed from the water.

There seems to be no satisfactory explanation for the loss of strength shown in the table, unless one can be found in the high percentage of sulphides, and that does not seem probable. The moral of the above account is that the usual tests of hydraulic cement do not always serve to exclude an inferior brand. The matter is thought to be worthy of space in your journal, as it may prove a valuable hint to those preparing specifications for important work.

Very truly yours,
S. Bent Russell, M.Am.Soc.C.E.

St. Louis, Mo., Nov. 23, 1898.

Notes of a Visit to the Keely Workshop.

Sir: The notice of the late John W. Keely, in your issue of Nov. 24, recalls an account which he once gave me of the origin of his so-called "motor," which may prove interesting to you. It was, I believe, in the summer of 1880, and during a visit to the workshop in Philadelphia, in company with some intending New York investors who did not invest. The usual exhibitions were made: of pressures of 10,000 lbs. per sq. in., produced after pouring of half a gill of water into the "generator," and the caterwauling of a bass viol; of lead bullets propelled from a gun with violence; of a rotary motor, which wobbled as if driven by a piston engine, and was easily stopped by a brake, etc., etc. In conversation afterwards, I asked Mr. Keely how he happened to discover his "motor." He said that many years previously he had been, for quite another purpose, trying experiments with various substances; that on one occasion these substances and mixtures were enclosed in a number of copper globes, and had been placed temporarily on a window sill. That he approached to remove them, when one of the globes suddenly exploded, knocking him insensible, and so far injuring his face and hands that he had to be put to bed and his wounds dressed by a surgeon. In that bed he laid a week, nearly blind, and mainly striving to remember accurately just what combination of substances he had put into that particular bomb. At last he recollected them all, he made up his mind as to the cause of the explosion, he jumped out of bed, he experimented, and his "motor" was the result.

All the prodigies exhibited to our party could have been reproduced by chemical means; for there are a number of alkali metals (sodium, potassium, etc.), which have so great an affinity for oxygen that they will absorb it from water or damp air, and release the hydrogen, which may reach a high pressure, if confined. The impression left on my mind, by my interview with Mr. Keely, was that it was possible that he was employing one of the alkali metals, perhaps in combination with other chemicals; that the mixture was previously introduced into the "generator," and came into activity upon the introduction of water. I do not claim that this is the way it was done, for I made no experiments, and took no further thought about the matter, being satisfied at the time that whether produced in this or in some other way, the enormous pressures generated were too erratic, and necessarily too small in volume, to be employed as a motive power.

It was also my impression that Mr. Keely originally had taken up his motor in good faith, and had anticipated a great success. After some years, however, he must have had doubts and then discouragements. This probably was the time when he resorted to the big fiddle (he played it very badly), to hasten by vibration the generation of pressure, or the trickling down of water through a narrow aperture, and invented the many puzzling words with which he interlarded his mystifying explanations. Once engaged upon that course, all his ingenuity would be devoted to guarding the secret which furnished him a living.

I hope you will carry out your expressed intention of giving an account of the investigations of your staff into this curious mystification.

Respectfully,
O. Chanute.

413 E. Huron St., Chicago, Ill., Dec. 13, 1898.

Notes and Queries.

B. K. C., Beaumont, Tex., asks as to the advisability of laying even or broken joints on a light unballasted railway in Southeast Texas.

Broken joints are preferable, and are the most generally approved, making a better running track with less maintenance work in surfacing and lining, especially if plain splice bars are used instead of angle bars. It is sometimes assumed that even joints are better in light tracks, but this is now generally recognized as being incorrect, in consequence of the additional work of maintenance required.

◆

THE MAIN ENTRANCE TO THE PARIS EXPOSITION of 1900, from the Place de la Concorde, is ingeniously planned. The ground plan is an equilateral triangle, surmounted by a dome; one side forming the entering façade. Arranged about the other two sides, in a semi-circle, are 108 passages for visitors, each fitted with a registering wicket. The interior apex of the triangles is cut off, and the dome is here supported on two piers with an arched passage between. This arrangement provides a driveway for special occasions, leading directly through the dome triangle into the grounds. It is estimated that this one gate will easily admit 60,000 persons per day to the Exposition. Architecturally the gate is a failure, but it will cost $38,000 to build.

◆

A DIFFICULT PIECE OF STEEPLE REPAIR is being performed in Boston by John H. Cunningham, of Providence. In the storm of Nov. 26-27, the rod supporting the vane on the steeple of the First Methodist Church was bent over about 50°. A staging was first built inside the top of the steeple, and then a hole, 20 ins. wide by 3 ft. long, was made about 18 ft. below the top. Through this hole a stout stick of timber, 34 ft. long, was pushed up and secured; and on this stick was a tackle and falls by which a boatswain's chair, with Cunningham on it, was hoisted up to the vane. This man first removed the letters on the vane-rod, which were 2 ft. long by 18. ins. deep. The vane itself will be taken down by means of another stick lashed to the first, which will carry a tackle by which it may be lowered to the steeple belfry. None of these adornments will be replaced as they are too heavy for the steeple. The "Lynn" method, here used for work of this character, implies working from the inside of a steeple or chimney, instead of building staging up on the outside, as was once done. In the case of a chimney, 30 ft. timbers are employed, placed diagonally inside and secured, and on top of each is placed another similar stick inclined in the opposite direction, until the top is reached and a secure staging is made. When the work is completed, the lower stick is pulled out and the rest drop to the bottom.

*Eng. News, Oct. 13, 1898.

THE CORNWALL BRIDGE ACCIDENT.

The uncertainty which prevailed at the time of the accident as to the original cause of the failure of the Cornwall Bridge has been cleared away somewhat by recent developments. This bridge crosses the St. Lawrence River in the vicinity of Cornwall, Ont., where Cornwall Island divides the river into two channels, and consists of a cantilever structure over the Canadian channel and a Pratt truss structure over the American channel. It was to the part over the American channel that the accident occurred (Eng. News, Sept. 15, 1898), and it resulted in the complete destruction of two of the spans and the pier between them. Fig. 1, from a photograph taken only a few hours before the accident, shows quite clearly the condition in which the structure was. The two spans shown in their entirety by the illustration were the ones which fell with the pier. At the time the erection of both spans had been practically completed, and from under one span the falsework had been removed. On the other span the blocking had been removed and the traveler was being taken down, and the men were at work riveting up the floor. This span was, in fact, ready to carry traffic, it being thoroughly bolted up and considerable riveting finished. The design and construction of the piers were fully described in Engineering News of Sept. 15, 1898, and at that time we also expressed the opinion that all the available facts pointed to the pier and not to the spans as the original cause of the accident.

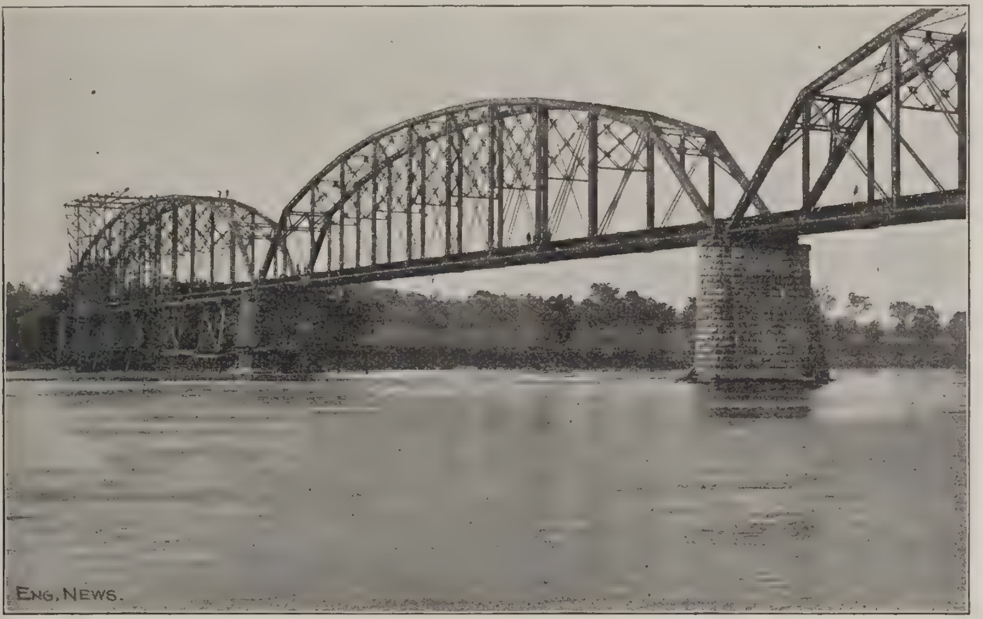

FIG. 1.—THE NEW YORK & OTTAWA R. R. BRIDGE OVER THE AMERICAN CHANNEL OF THE ST. LAWRENCE RIVER, NEAR CORNWALL, ONT.
(From a photograph taken on the morning of Sept. 6. The two spans shown and the center pier fell at noon on that day.)

With the purpose of determining the responsibility more definitely, and also of inspecting the wrecking operations, a member of the editorial staff of Engineering News visited the bridge on Oct. 17 and 18, and studied the ground and interviewed all persons likely to possess authentic information upon the accident. The officers of the New York & Ottawa R. R. Co., the owners of the bridge, refused to give any information. In other directions the success of the inquiry was greater, and a number of persons familiar with the structure and competent to judge of the conditions and circumstances gave valuable information. For various personal reasons we are not at liberty to divulge the names of the gentlemen who aided our representative. A careful comparison of the different statements, however, has been made, and the inconsistencies weeded out as far as possible, so that we believe that the following statements are as nearly accurate as the present knowledge of the accident permits.

So far as could be ascertained, no examination was made to determine the character of the bottom of the river previous to the sinking of the cribs for the piers. The only difficulty in making such an examination arose from the swiftness of the current, which ran about five miles per hour at the bridge site. The bottom was successfully examined with a sounding rod in a stronger current, however, after the pier fell. After the cribs were sunk a diver went down inside them and examined the bottom. In the case of the crib which failed, the diver, it is stated, reported that the bottom was hardpan, and brought up a sample to prove his statement. No borings or soundings were made inside the crib to verify further the diver's report or to determine the depth of the hardpan layer.

The whole region surrounding the bridge is clayey. On the Canadian side of the river this clay is hard, but it becomes softer as the American shore is reached. It is, geologically, a glacial drift deposit of clay interspersed in places with deposits of boulders, and a formation which is frequently encountered is a layer of boulders and indurated clay, known locally as hardpan, overlying a deposit of soft blue clay. Such a formation is found in a number of places on the St. Lawrence Power Co.'s canal (Eng. News, Dec. 15, 1898), only a few miles distant.

In erecting the falseworks for the spans it was observed that the bottom was very uncertain. Fig. 2 shows the falseworks in process of erection. It will be noticed that the trestle bents are made up of Phoenix columns braced together by iron rods and timber struts. At the bottoms of these columns were fastened circular shoes or disks 2 ft., and, in some cases, more in diameter. The purpose of these disks was, of course, to give the iron posts greater bearing surfaces on the river bottom, and with a bottom of hardpan such as the piers were supposed to rest on, the size of the disks used was calculated to be ample to prevent any settlement. This did not prove to be the case, however, for, although an extra length was added to the bent posts to allow for settlement, they sunk more than was assumed in several cases. This extra sinking of the bent posts was noticed on both sides and close to the pier which was destroyed.

The destroyed pier was located slightly diagonal to the direction of the current, and had no protection of rip-rap to prevent scour. The ultimate intention was to rip-rap all the piers thoroughly, but this work had not been done. Any scour, therefore, which might be induced by the diagonal position of the pier and the restriction of the channel by the piers and falseworks had an entirely unprotected bottom to act upon.

So much for the conditions previous to the accident. At the time of the accident gas pipe soundings were being made in the Canadian channel of the river by the engineers of the Canadian Department of Railways and Canals, and shortly afterwards the barge being used there was moved around to the American channel and work begun over the site of the destroyed pier. After penetrating about 18 ins. to 2 ft. of hardpan the sounding rod struck a soft clay, into which it was forced from 12 ft. to 18 ft. without difficulty by a man pushing downward on it. The wooden crib had crushed through the shell of hardpan and tipped onto one edge, and the masonry had disappeared. It is surmised that the soft material under the hardpan was a deep pocket formation. Soundings have shown that no such formation exists in the Canadian channel of the river, but, so far as is known, no other soundings of a similar nature have been made in the American channel. It was, however, just such a formation as is found frequently in the surrounding country.

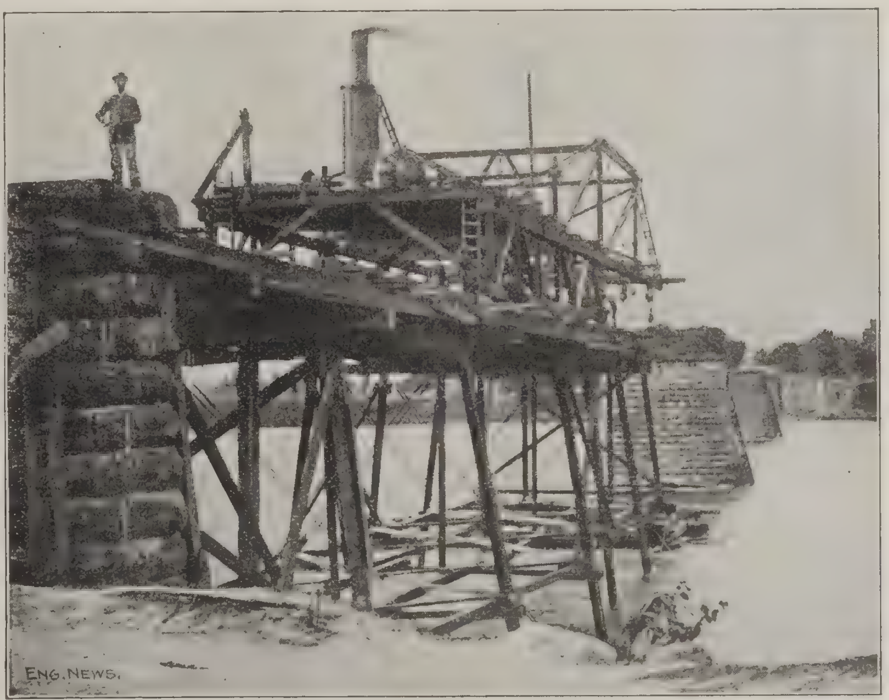

FIG. 2.—VIEW SHOWING CHARACTER OF FALSE WORKS AND TRAVELER USED IN THE ERECTION OF THE CORNWALL BRIDGE.

The evidence pointing to the failure of the pier first is both direct and inferential. The survivors of the accident who were at work on the destroyed pier state that it literally sunk from under them. It is difficult to conceive under the conditions how it would be possible for the failure of a member in either of the spans to pull the pier over and destroy all vestiges of it completely. Moreover, the span from which the falsework was removed fell perfectly intact, except for the end panel, which rested on fallen pier, according to the examination made by the wrecking company's divers. It pretty certainly did not break in two and drag the pier down. The fact that the pier had shown no signs of failure also agrees in every respect with what one would expect should the pier break suddenly through a shell such as the soundings showed to exist.

As stated above, the second span from the American shore fell into the river intact, and now lies on its side with the upper chord downstream. The shore span, however, carrying the falseworks with it, fell in a tangled mass, occupying the space between the piers. Work was in progress removing the wrecked ironwork at the time our representative made his examination. To take out the wreck of the shore span a winch has been fitted upon the shore pier. The tackle from this is fastened to the wrecked members, which are hauled ashore. Dynamite placed at the connections is employed to break up the wreckage into pieces small enough to be handled. About one-fifth of the wrecked steelwork had been removed on Dec. 15.

The second span it is proposed to raise as a whole by means of pontoons and thus float it to shallow and quiet water, where it can be broken up. The span is now lying on its side with its top downstream. It is proposed to attach a cigar-shaped pontoon to each of the ten vertical posts. Each pontoon is 8 ft. in diameter and 40 ft. long between its extremities, and has a lifting capacity of 60 tons. Altogether the ten pontoons can thus exert a lift of 600 tons. The fastenings are made by chains between the panel points and the ends of the pontoons, that is, the pontoon lies on top of the span, parallel with the vertical post and the current, with one end chained to the top chord panel point and the other end to the bottom chord panel point. At the time of our representative's visit, work was in progress attaching the pontoons to the wrecked span. Since then the span has been moved downstream about 300 yards and into shallower water, thus forcing the pontoons nearly half their diameter out of water, and consequently destroying their usefulness. The wrecking company has abandoned the work for the winter.

One of the novelties of this work was the working of divers behind shields. With the wreck restricting the channel the current is like a mill race, and it is absolutely impossible for a diver to work in it unprotected. The protection adopted successfully is a steel plate, half-cylinder, 4 ft. in diameter, with a 1 ft. tangent plate at each free edge. Across the open front, between the free edges, are horizontal braces arranged like the rungs of a ladder. This cylinder is hung from the boom of a derrick on a large working barge, and is guyed to ensure its descent vertically into the water. In operation the shield is placed so that its opening covers a panel point, the curved surface being upstream. A diver descending inside the shield is thus thoroughly protected from the force of the current and can attach the chain to the panel point at his convenience. So far as the work had gone at the time of our representative's visit, no accidents had occurred with this shield, and it was doing successfully what it was designed to do. The contractors for the wrecking operations are the Collins Bay Rafting & Towing Co.

A 60-IN. HYDRAULIC VALVE.

In our issue of Aug. 20, 1896, we described a 42-in. valve operated by hydraulic power, a number of which had at that time just been installed on a 42-in. pipe line of the Detroit, Mich., water-works. These valves were designed and built by the Michigan Brass & Iron Works, of Detroit, Mich., and the same firm has recently completed a 60-in. valve of similar design for a water power electric plant at Ft. Ann, N. Y., which we illustrate in the accompanying drawings. These drawings show the nature, arrangement and dimensions of the different parts in detail, and will for that reason be of interest to engineers.

The valve was designed for the flume which conveys the water from the dam to the water wheels in the Ft. Ann, N. Y., electric plant. Here it will be used to shut off the water in case of accident or any other emergency in which prompt shutting off of the water becomes necessary. The pressure employed in testing the valve before shipping it was 75 lbs. per sq. in. Some idea of its size is obtained from the statements that its height is 42 ft., and its total weight is 27,400 lbs. Over 1,500 lbs. of bronze were used in its construction. The several features of construction and operation of the valve are clearly shown by the drawings, and need not be explained further here. For the information from which this description has been prepared we are indebted to Mr. Frank B. Ward, Secretary and General Manager, Michigan Brass & Iron Works, Detroit, Mich.

STREAM GAGINGS AND OTHER STUDIES RELATING TO IRRIGATION IN WYOMING.*

By Elwood Mead, M. Am. Soc. C. E.†

During the past two years, C. T. Johnston, Assistant Engineer, has given the greater part of his time during each irrigation season to the gaging of streams and looking after the records of their discharges. This work was done for the hydrographic branch of the U. S. Geological Survey, which paid all the expenses, but gave this office copies of the results. In September of this year, Mr. Johnston was employed by the Department of Agriculture in the study of some interstate water right questions in which Wyoming is conecrned. The facts gained in this investigation have also increased our knowledge of the irrigation problems which must in time receive attention from Congress or the courts.

In addition to these measurements, the office made some special investigations into the water supply of several streams, the results of which seem worthy of a place in this report.

Discussions of stream discharges and laws for acquiring rights therein seem to assume that the volume to be divided can be readily ascertained and that all those in charge of the streams have to do is to measure the flow and then apportion it out among users in accordance with their priorities of right. Those who have charge of this division find this conception does not always agree with the facts. Of all the adjudicated streams in Wyoming, I cannot think of one where gagings at one point, no matter what place is selected, will give the volume which can be utilized by irrigators. On many streams irrigators divert the entire flow. Where this is done we are able to locate the sources of that supply and observe its fluctuations to much better advantage than before such diversions were made. In these studies we have found that subterranean waters are of much more importance than was formerly supposed. On some streams springs furnish the main supply; on others, crevices in the rocks are the cause of large losses. Among the adjudicated streams of this state, very few are like canals—simply a channel to transport what is turned in at the head. On the contrary, they gain and lose in every mile of their channel. The inclination of the underlying strata often has more influence on a creek's flow than the area of its mountain watershed. Some streams have a large volume where their channels cuts across a rock ledge, while in sandy basins above and below the visible supply will wholly or in large part disappear. Because of these fluctuations the location of a right is often of more importance than the number of its priority. In order to conserve the water supply and secure the most effective division of a creek or river, these changes in the available volume have to be taken into account. They cannot be obtained from a gaging record secured at a single station. What is needed is a careful study of physical conditions along the entire stream.

The experience of our water commissioners would furnish as many illustrations of the truth of these statements as there are rivers to divide. Only a few can be given. We will begin with Salt River, which waters about as many acres of land as any stream in the state, and where the enforcing of rights is about as perplexing as can be imagined. Where this river leaves the mountains it has a perennial flow; so it has at the narrows, 25 miles below; midway between these two points it goes dry every summer. The closing down of every ditch on the main stream and all its tributaries above this dry section would not furnish water to appropriators along it. When I crossed it near Fairview several years ago its channel was as dry as the streets of Cheyenne, while 11 mines below the river was larger than North Platte on the same date.

The North Platte is another, but less striking example. For many years a gaging station has been maintained at Orin Junction. It is an excellent location, and the record is of value in view of possible interstate complications, as the station is below all ditches of any size in Wyoming, and the flow measured gives a close approximation of the surplus which remains for irrigators below. The volume taken out in Wyoming below the station is less than is received from Laramie River, so that when there is a 1,000 sec.-ft. in the river, at the station there should be as much or more for Nebraska's irrigators at the state line. The facts are otherwise. Last july, when 900 sec.-ft. was flowing past the gage rod at Orin, a hot and thirsty representative of Nebraska's irrigators protested against the stream being dried up by Wyoming ditches. He was correct about the river being dry. I crossed it on the Burlington Railroad, near Grand Island, and nothing but a succession of pools was left of the torrent which at that minute raged through the canyon 50 miles west of the Wyoming state line. The water was gone, but it did not depart in ditches. It disappeared in the sand through which the stream winds its devious way. In September the discharge at the gaging station was about 500 sec.-ft. Not 100 sec.-ft. of this was taken out between that point and the eastern border of the state, and the volume diverted was offset by what the Laramie supplied, yet, before the border of Nebraska was reached the water had all disappeared. The channel was nearly dry at the state line. In less than 100 miles over 400 sec.-ft. had gone into the air by evaporation or sunk into the sand by percolation. If, instead of one station on the river, there had been three, one at the Colorado-Wyoming boundary where the river enters the state, another at the Nebraska-Wyoming border where it leaves, and the one at Orin where its present diversion now practically ends, the three records would have little resemblance to each other, while their differences would have no relation to the use of water by irrigators. The loss of over 400 sec.-ft. between Orin and the state line really occurs in half that distance. Gagings made at Fairbanks, 50 miles nearer Nebraska, show a greater discharge than at Orin. The causes of the fluctuations are not at all obscure. Less than a mile below Orin the river cuts across a rock ledge which brings the underflow to the surface. This permits nearly, but not all to be measured. At Fairbanks, a vertical marble dike cuts across the valley. Every particle of water which gets past this has to flow through the narrow notch which the river has eroded. Whatever underflow escapes at Orin is in evidence here. At the state line the river has a broad, shallow bed winding in and out among islands and sand bars, where every condition favors its rapid absorption both above and below.

The report of Mr. Gilcrest shows that the streams, on which he surveyed the ditches in 1897, are divided into sections which are, in a large measure, independent of each other, so far as the enforcement of prior rights or the use of available supply is concerned.

---

*Extracted by permission from the forthcoming annual report of the author, as State Engineer of Wyoming.

†State Engineer, Cheyenne, Wyo.

The gaging station at the mouth of the La Prele, maintained by this office in 1897, showed how much water escaped, but it gave no indication of how or where it could have been used to the best advantage.

Horse Shoe, Cottonwood, Chugwater, Lodge Pole, Crow and Lone Tree creeks are examples, in Laramie county, of streams which each year become dry, or almost so, in places, and have a perennial flow in other sections. There is little use in trying to enforce priority of right across some of these dry stretches. The water required to saturate these basins of sand will, if used where it rises, save many acres of crops. The loss of over 400 sec.-ft. in 50 miles of the North Platte is evidence of this. The truth is that each stream is in a measure a law to itself, and conditions along one are no guide as to what they will be on another.

The rise of water in some sections of a stream and its disappearance in others creates some perplexing questions. Many of the earlier ditches were located before these facts were known, and before the extent of the water supply was much thought of. As a result, headgates were placed on sand bars where 10 sec.-ft. has to sink beneath the channel in order to keep one in sight. The loss in putting water into such ditches is, therefore, heavy and other appropriators object to the waste, as they term it, which the enforcement of these rights involves. The members of the Board of Control hold different views regarding our duty in such cases. Some are of the opinion that where the protection of a priority involves an excessive loss, the right should be ignored and the water be given to later appropriators, who can use it to better advantage.

I do not believe we have such discretionary authority. The law gives the first user the better right. It left him free to locate his ditch where he pleased, without regard to the abuses which this absence of direction or control might create. The right cannot, therefore, be disregarded without setting aside the whole theory of prior rights and violating the law creating them. I believe that so long as the law is in force these priorities should be recognized, unless it can be shown that there is not water enough in the stream to supply both the waste and the use combined. If doing this involves a loss to others of such proportions as to make the existence of this right a public injury, the law should be changed. Permanent relief will not come from disregarding statutes, but through their modifications. Let a law be passed to condemn such wasteful rights, other appropriators to pay the costs incurred in proportion to the benefits received.

Influence of Subterranean Waters on the Flow of Streams

In the adjudication of water rights, and in most court decisions affecting those rights, the stream disposed of is treated as though it all had come and was to come from one snow bank, or in other words, as if all the rights established were to be supplied from a single and common source.

Because of this premise it has been held that so long as the supply comes from the same source the place of diversion and use is immaterial, and that the holders of water rights should be permitted to shift their appropriations from one ditch to another and move their priorities up stream or down, as interest or inclination may dictate. Those who uphold this doctrine appear to take it for granted that no matter where the original right was acquired the appropriator took from a supply which included all the water in the stream. The soundness of this doctrine depends, in a large measure, on whether it agrees with the facts. If all the water a stream carries enters above an appropriator's ditch, the claim that the place of diversion is not material has much better foundation than it has where the greater part comes into it below. It has never been held that the beneficial use of water from a particular source gives a right to water from a different one. The first appropriator from Crow Creek cannot transfer his priority to Lodge Pole, and take the water away from the second priority there. Using water from the North Platte gives no right to Green River. So far as streams are concerned, rights are restricted to the source from which originally acquired.

I can think of no reason why such limitation should not apply to rights from a single stream. If it does, then the man who builds a ditch at the head of a creek has no license to move his priority down stream in order to get control of an additional supply which his original ditch could not divert. An irrigator on the Laramie Plains, taking water from the Laramie River, has, in my opinion, no right whatever to Sybille Creek, even if it is a tributary, because it rises on the other side of a range of mountains and joins the river 2,000 ft. below his ditch. To permit the shifting of his priority so that he could take the volume designated in the right out of the river below the mouth of Sybille Creek, would be to recognize control over a stream as foreign to the original appropriation as to transfer the priority to an entirely different watershed.

The experience gained in the division of Wyoming streams has shown that the number in which the rights are based on the entire supply is exceedingly limited. On the contrary, most streams are fed from a multitude of sources, some of which are below many early rights, and hence furnish a supply which was never used by the holders of these rights.

The limit of this report prevents the publication of all the investigations which have led to these conclusions. Like the maps of surveys, we can only present one or two typical examples. The results of the Horse Creek measurements, which follow, could be duplicated by as marked gains or losses on scores of other streams where similar measurements have been made.

The Water Supply of Horse Creek.

Horse Creek rises in the Black Hills, on the western border of Laramie county, and empties into the North Platte near the Wyoming-Nebraska boundary. It is over 100 miles long, but with one exception, all of the ditches now in use are found between the base of the foot-hills and Hawk Springs, a distance of 70 miles. The adjudicated rights are largely in excess of the stream's discharge, as they aggregate over 1,200 sec.-ft., yet they are derived from a creek whose greatest measured discharge is 32 sec-ft. Practically all the surface supply comes from the mountains at the head. Only two small creeks join it below, and one of these formerly ran dry during the greater part of the irrigation season. The other is over-appropriated and nothing but seepage water comes from it. The first ten priorities aggregate 35 sec.-ft. Hence, if the stream was not reinforced except by surface tributaries, these priorities would absorb the largest flow ever measured, and leave irrigators with later rights, amounting to over 1,100 sec. ft., with a lot of paper priorities of little or no value. This is not the existing situation. Certain irrigators, whose priorities are far down the list, have always an ample water supply. Others with early rights have an intermittent and scanty supply. This is not due to the improper division, but to the fact that the ditches are so located that earlier rights just above drain the creek, while farther down, seepage and spring waters reinforce it. Measurements, extending over a period of ten years, have proven that the greater part of the water supply in this stream does not come from the foot-hills, but from the seams in the rock ledges it cuts across. Some of these springs are large—one has a flow of 3 sec.-ft.—but the greater number are so small that they have not been located. In order to show more definitely the extent of this increase, two series of measurements were made this year, the first in May and the last in August. The method pursued was to follow down the stream and wherever a ditch was diverting water the volume taken out was measured, as was the discharge of the stream immediately below the headgate. Adding the two gave the volume above the headgate. These gagings began just outside the foot-hills where the three branches of the creek unite. They ended where Hawk Springs enters the stream over 70 miles below.

The rainfall in May was above the average, and its influence on the first measurements was apparent. While there were no surface streams, the ground was wet and the flow of springs much larger than usual. The August measurement was made during one of the dryest periods of which we have any record. In May the discharge above all ditches was 18.3 sec.-ft.; to this was added the surface flow of Sprager Creek, Little Horse Creek and Hawk Springs, amounting in all to 8.62 sec.-ft. Hence, if none were lost by evaporation in the 70 miles, the total surface supply would be 26.9 sec.-ft. There was taken out over 85 sec.-ft., and the last measurement showed 17 sec.-ft. still in the stream, an apparent loss of less than 10 sec.-ft. for evaporation in the creek channel, and in the use of 85.6 sec.-ft. in irrigation.

When the August measurements were made the irrigation of grain and pastures had ended and some of the ditches in use in May were dry. The first four ditches measured in May were in this condition. While there was a decided shrinkage in the amounts of all measurements, except the seepage from Sprager and Little Horse creeks, the relative importance of the subterranean supplies added to the stream was not diminished.

The amount of water above all ditches was less than 6 sec.-ft. That was the limit of the common supply. Whatever was added below could not be diverted or used by the upper ditches; 17.47 sec.-ft. of seepage and spring water was so added and 4.44 sec.-ft. entered from the two tributary creeks. In both measurements about four times as much water was taken out as there was in the stream at the start, and in both cases approximately as much remained at the end as there was at the beginning.

The subterranean increase comes from two sources. The winter snow and spring rains fill the cavities of the rocks and this finds its way slowly into the creek channel where it cuts through these ledges. The increase between the 10 and 40-mile points is largely from this source. For 15 miles of this distance the creek flows through a canyon with no ditches and no seepage from irrigation. That water from irrigated fields formed a considerable part of the August increase was shown by the fact that the volume of seepage water flowing out of the two tributary creeks showed no material diminution. There is also reason to believe that there has been a progressive increase in the amount of irrigation water which returns, as a comparison with similar measurements described in the report for 1889 shows a considerably larger percentage of increase.

This progressive increase in the water which returns from irrigated fields has been clearly shown on Horse Shoe Creek. For ten years after ditch building began no land was irrigated for two or three miles above the mouth of the stream, although the land was fertile and ditch building easy. Ditches above drained the channel; newcomers were afraid to settle below them. They went higher up stream to get nearer the original supply in an effort to make position offset priority. But when the upper part of the creek had become unquestionably over-appropriated springs began to appear near its mouth. While the upper ditches were being closed down to protect early rights water was going to waste at the mouth of the creek. One ditch was built to use it. Later a second ditch was built and the farms under them although last in priority have all the water needed.

On some streams the volume of return or seepage water is small and does not seem to increase. This appears to be due to the underlying strata being inclined away from the channel instead of toward it. Spring Creek, a tributary of the Platte, is an instance.

This office is frequently requested to approve changes in the place of diversion and use of appropriations. The holders of early rights, which experience has shown to have little value, desire to move them to some other point on the stream where, from the influence of seepage or other causes, the supply is more abundant. In some cases the request comes from a speculator who sees in these early paper rights a chance to blackmail later appropriators whose ditches are located where the supply is more abundant. I have refused every such request and have notified every one that until either the legislature or courts make the right to move a priority absolute I shall do all in my power to prevent such transfers and to avoid our repeating the blunder made by some of the other arid states. In my opinion this office can do the irrigators of the state no greater service than to prevent the abuses which in all countries have followed the recognition of such right.

I can seen no more reason for permitting an early appropriator near the head of Horse Creek to move his priority down the stream to get the benefit of the springs which he never used than there would be to sanction the transfer of his priority to the Laramie. In both cases it would enhance the value of the migratory right, but it would rob some other appropriator and unsettle and demoralize our whole irrigation system.

TEST OF AN ALLIS PUMPING ENGINE AT ST. PAUL, MINN.

A new triple-expansion, high-duty pumping engine of 10,000,000 gallons daily capacity, built for the Water Commissioners of St. Paul, Minn., and erected at the McCarron Lake pumping station in that city, has recently been given a 72-hour test, with very satisfactory results.

The test was started at 7 p. m., on Nov. 13, and concluded at 7 p. m., Nov. 16. All the steam used by the engine was condensed and weighed, and the condensation from the jackets was collected and weighed separately. The water delivered was measured by a weir situated at the reservoir, and readings of this weir were taken at frequent intervals. The water pressure was read by means of a mercury gage.

The engine was built by the E. P. Allis Co., of Milwaukee, Wis., and was completed some months before the foundations were ready for its erection. Under the contract, the builders were to receive a bonus of $600 for every million ft.-lbs. of duty secured above 130,000,000 ft.-lbs., up to $6,000, and the tests show that they are entitled to the maximum amount of the bonus. The test was made by Robert W. Hunt & Co., of Chicago, to which firm we are indebted for a copy of the preliminary report, and for the following statement of the dimensions of the engine and the result of the test:

Diameter of h.-p. cylinder	21½ ins.
" i.-p. "	38 "
" l.-p. "	56 "
Diameter of plungers	24¾ "
Stroke of pistons and plungers	42 "
Plunger displacement, per revolution	262.42 U.S. galls.
Average: Steam pressure by gage (corrected)	127.9 lbs.
First receiver pressure by gage	31.8 "
Second receiver pressure by gage	.28 "
Vacuum by gage	12.83 "
Discharge head on pumps	146.638 ft.
Suction	.052 "
Total head on pumps	146.586 "
Total revolutions of engine	116,649
Average revolutions per minute	27
Actual total water pumped during test, weir measurement	254,308,222.97 lbs.
Actual water pumped for 24 hours	10,159,000 galls.
Loss by slip and leakage	0.44%
Total condensed steam	219,601.5 lbs.
" jacket steam	38,443.5 "
" dry steam supplied to engine	258,045 "
Duty per 1,000 lbs. steam	141,463,000 ft.-lbs.

The engine is of the vertical, triple-expansion, crank and fly-wheel type, the arrangement being somewhat similar to the ordinary type of marine engine. There are three steam cylinders (high, intermediate and low pressure), 21½, 38 and 56 ins. diameter, and 42 ins. stroke. Each steam piston rod connects to a steel cross-head, from which four steel-tie rods extend to the head of the pump plungers, making a direct and rigid connection between the steam pistons and water plungers. The main shaft has three cranks set at angles of 120°, giving a steady turning effect, and as the pump plungers move in unison with the cranks, a very steady flow of water is obtained, and the shock on the pumps and pipes is reduced to a minimum.

The steam cylinders are steam-jacketed, thoroughly covered with a non-conducting material, and lagged with sheet steel. The valve gear is of the Reynolds-Corliss type, the high pressure gear being under the control of an adjustable speed regulator, while the intermediate and low pressure cylinders are adjusted by hand. The steam and exhaust valves are located in the cylinder heads, reducing the clearance to a minimum (2% in the high-pressure cylinder, 1.6% in the intermediate, and 1.37% in the low pressure).

The pumps are located below the engine bed plates, and are of the single-acting, outside-packed, plunger type, provided with large valve area, the valves being of rubber and arranged in groups mounted on "cages." The valve chambers support one end of the engine bed plates, this arrangement reducing the amount of foundation required, while at the same time it renders the pumps more accessible. The opposite end of the bed plates is carried on a masonry pier.

A surface condenser is located in the suction pipe. The air and feed pumps are driven direct from the main engine by means of an arm on the low pressure plunger. The throttle valve, injection valve for condenser, cut-off levers, etc., are all so placed that the engine can be stopped, started and controlled from one position on the engine-room floor. The total weight of the engine is 200 tons.

The engine has a capacity of 10,000,000 gallons in 24 hours, when operated at a plunger speed of 189 ft. per minute (27 revolutions). The pump HP. during the test was 262.47; with 279.56 I. HP., the friction being 6.11%. The steam consumption was 12.82 lbs. per I. HP., the steam pressure being 127.9 lbs.

During the test steam was applied by two horizontal tubular boilers, each 5½ ft. diameter and 18 ft. long, but as the duty test was on steam, no effort was made to obtain high boiler efficiency. In fact, the builders state that the conditions were poor for high boiler efficiency, the actual evaporation being only about 7.57 lbs., while under ordinary conditions the boilers readily evaporate 8.5 lbs.

TESTS OF A DIESEL MOTOR.

We have received from the Diesel Motor Co., of America, 11 Broadway, New York city, a pamphlet containing a report by Prof. James E. Denton, of the Stevens Institute of Technology, of the principal results of a series of economy tests of a Diesel motor, rated at 20 brake HP., using various kinds of oil as fuel. The motor is one of the first made for the market in Germany, and is the first that has been brought to this country. It was erected at the Electrical Exhibition held last spring in New York city, where it drove an electric light plant for five weeks. It was then erected for the purpose of the tests at No. 24 West St., New York city. The results confirm those obtained from similar engines in Germany, and are worthy of record as marking a long step forward in the economy of oil engines. We give a condensation of Prof. Denton's report below:

Description of Motor.

The motor has one main cylinder 10.23 ins. diameter and 16.16-in. stroke. The piston, which is exposed to the atmosphere on its under side drives the main crank by direct connection, and an air-compressing pump, about 3.5 ins. diameter and 8.05-in. stroke, through a lever. Two poppet valves in the main cylinder head control the introduction of air from the atmosphere to the main cylinder and the exit of the contents of the main cylinder during exhaust. A smaller poppet valve introduces fuel, which is fed from an oil tank by a small pump. A fourth poppet valve controls the introduction of air from the air receiver for the purpose of starting the motor. The operation is as follows:

The receiver is charged with air at the desired maximum pressure (about 600 lbs. per sq. in.). To start the engine the piston is placed at the top of its stroke. A hand-starting lever is set so that all the cams upon the valve shaft are inoperative except the one connected to the starting valve, which then holds the latter open. The oil pump is operated a few strokes by hand, whereby the space around the stem of the starting valve is supplied with oil. On opening a cock by hand, the pressure from the receiver acts upon the piston and starts the latter downward. At the end of the down-stroke the rotation of the cam shaft has automatically closed the starting valve, and put the three operating valves into regular action. The momentum acquired in the down-stroke carries the piston through an up-stroke, and compresses the contents of the main cylinder to about 520 lbs. per sq. in., whereby they are heated to a temperature of upwards of 1,000°F. As the piston starts to make another down-stroke by momentum, the fuel valve opens, and the 600 lbs. of air pressure in the receiver acting upon the fuel forces it into the heated contents of the cylinder, thereby causing combustion to occur, and power to be developed throughout the second down-stroke, the fuel valve closing at about one-tenth of the stroke of the piston, so that the heat developed is applied with a high degree of expansion. On the next up-stroke the exhaust valve is opened, permitting the cylinder to exhaust itself against the atmosphere. During the next down-stroke of the piston the inlet valve connecting with the atmosphere, supplies the cylinder with pure air. This is compressed on the return stroke, and oil again introduced, and thence the operation of the engine proceeds regularly.

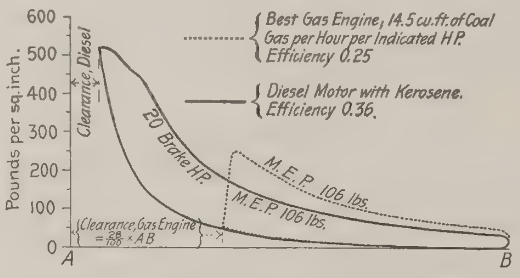
The pistons of the main and air cylinders are lubricated automatically from a reservoir.

The revolutions of the engine are governed by a fly-ball governor, which controls the effective length of the stroke of the oil-feeding pump.

The engine was provided with a fly-wheel, 6½ ft. diameter, weighing about 2,800 lbs. Its total weight, including fly-wheel, was about 600 lbs. per rated brake HP., which is about 70 lbs. greater than that of a Priestman oil engine, of 7 brake HP., running 208 revolutions per minute.

The distinctive thermodynamic features of the engine compared with existing explosive gas and oil engines are:

1. That the cylinder contents during compression consist of air only, so that the compression may cause a pressure at the end of the in-stroke far above that which would cause premature explosion in a gas engine, or explosive oil engine.



Comparison of Indicator Diagrams from a Diesel Motor and from the Best Gas Engine.

2. The greater degree of compression confines the contents of the cylinder when combustion occurs to about 0.07 of the cylinder volume, whereas in explosive gas or oil engines they occupy about 0.28 of that volume. (See cut.) Consequently in the Diesel motor the available rate of expansion of the heated contents of the cylinder is several times as great as that of the gas and oil motors, and, therefore, the theoretical proportion of the heat of combustion utilized in work upon the piston is about 20, 25 and 36%, respectively, for the best explosive oil engine, gas engine, and Diesel motor.

3. The fuel in the Diesel motor burns gradually in the cylinder, during the first one-tenth of the stroke (as does oil which is burned under a steam boiler), without augmenting the pressure above that due to the compression of the contents of the main cylinder by its piston. Consequently the particular proportion of air to fuel necessary to secure explosion is unnecessary. The proportion of air to fuel may be anything, provided there is air in excess of that required for combustion. The proportions of this engine permit the excess to be about 25% at full load, and the presence of this excess of air ensures the steady maintenance of perfect combustion, which, together with the relatively small clearance space as compared to that of explosive engines (see cut), protects the engine against unreliable acting from fouling of the cylinder under continued action.

Results of Experiments.

Tests were made with ordinary domestic kerosene, and with the various grades of petroleum used as fuel under steam boilers, which covered the operation of the engine for upward of 250 hours, to observe the behavior of the oil, and the conditions of the interior of the engine after using each oil. During this time economy tests were made of from 1 to 10 hours' duration, as per the data in Table I. The principal commercial results abstracted from this table are as follows:

1. With ordinary colorless domestic kerosene, of 120°F. flash, 150°F. fire test, and 0.784 gravity, at about 187 revolutions per minute, an average of 20.8 brake HP. was developed, with an oil consumption of 0.534 lbs., or 0.082

U. S. gallon per hour per B. HP.; 13.05 B. HP. with an oil consumption of 0.586 lbs., or 0.0896 U. S. gallon per hour per B. HP., and 8.78 B. HP. with an oil consumption of 0.72 lbs., or 0.110 U. S. gallon per hour per B. HP. This shows an efficiency on B. HP. of 25.8, 23.5 and 19.0% respectively. The corresponding indicated horse-power efficiencies were 37.7, 41.8 and 41.2% respectively. These results practically confirm the tests made on an engine rated at 19 B. HP., at Augsburg, Germany, by Professor Schroeter and other experimenters, which for 17.33 English HP. showed an oil consumption of 0.54-lb., or 0.0819 U. S. gallon of American kerosene per hour per B. HP., and for 9.315 English HP. an oil consumption of 0.63 lb., or 0.0956 U. S. gallon per hour per B. HP., the efficiencies being as follows.

	Per cent. on 17.33 HP.	Per cent. on 9.315 HP.
Thermal efficiency on indicated HP...	34.15	38.18
Thermal efficiency on brake HP.......	25.81	22.12

The same increase in indicated efficiency with reduction of load to one-half, shown by the German tests, is found in the New York tests, The mechanical efficiency, or the per cent. of the indicated power utilized at the brake, of the New York motor was not as great as that of the motor tested in Germany—a result which is possibly attributable to the insufficiency of the foundation of the New York motor, which by permitting excessive vibration, may have caused a waste of power between the cylinder and the brake. The New York motor showed the greater indicated efficiency, however, which is probably due partly to the slight difference of maximum pressure, and partly to the higher temperature of cooling water reducing the jacket waste.

The heat balance for the two cases is as follows:

Heat Balance.

	Brake HP.			
	21.51	8.78	17.33	9.315
	New York.		Augsburg	
Heat*	37.2%	41.2%	34.7%	38.9%
Removed by jacket	35.4%	37.4%	40.3%	45.1%
Remainder	27.4%	21.4%	25.0%	16.0%
Total heat of combustion.	100.0%	100.0%	100.0%	100.0%

Examination of the interior of the engine during the use of the kerosene showed that there was no deposit on the surfaces, other than an infinitesimally thin film of lampblack on the cylinder and piston head, which did not increase with time. The bore of the cylinder was clean and polished.

2. With Pratt's fuel oil, which is a dark, straw-colored, clear petroleum, of 200°F. flash, 268°F. fire test, and 0.852 gravity, considerably used as a steam-boiler fuel, at practically the same revolutions, 20.07 B.HP. were developed with an oil consumption of 0.613-lb., or 0.0862 U. S. gallon per hour per B. HP.; and 12.56 B. HP. with an oil consumption of 0.681-lb., or 0.0958 U. S. gallon, per hour per B. HP. The operation with this oil was attended with the same insignificant lampblack deposit.

3. With a black, clear, Pennsylvania petroleum, known as "Eagle" fuel oil, of 249°F. flash, 296°F. fire test, and 0.849 gravity, at practically the same speed, 20.75 B. HP. were developed with an oil consumption of 0.56-lb., or 0.0784 U. S. gallon, per hour per B. HP. This oil left absolutely no deposit in the cylinder.

4. With Lima fuel oil, a black, clear petroleum of 0.856 gravity, at about the same speed, 20.73 B. HP. were developed with an oil consumption of 0.59-lb., or 0.0826 U. S. gallon, per hour per B. HP.; and 10.77 B. HP. with an oil consumption of 0.672-lb., or 0.0941 U. S. gallon, per hour per B. HP. The operation with this oil was attended with no deposit in the cylinder whatever.

5. With California crude oil, a black, clear petroleum of 0.846 gravity, with practically the same revolutions, 20.07 B. HP. were developed with an oil consumption of 0.626-lb., or 0.0887 U. S. gallon, per hour per B. HP., and 11.44 B. HP. with an oil consumption of 0.699-lb., or 0.099 U. S. gallon, per hour per B. HP. This oil left absolutely no deposit in the cylinder.

With all these oils the engines started instantaneously and operated very steadily. The action of the valve gear is very smooth, and practically noiseless. The combustion occurred with perfect regularity, and was accompanied with no noise other than that due to the pulsation of the floor under the engine. There was also no noise from the exhaust of the engine audible a few feet distant from the chimney into which the exhaust pipe led.

The exhaust gases with all of the oils carried no soot, a piece of white paper being unsoiled by the impingement of the gases against its surface.

No deposit was found in a drum, forming part of the exhaust pipe, after the entire 250 hours of operation of the motor.

The cooling water is shown in Table I. to be 60 lbs. per B. HP., with an outflow temperature of 127°F. The engine operates safely, however, with water leaving the jacket at 140°F., which would reduce the water to about 50 lbs., or 6 gallons per hour per B. HP. The quantity of water used does not, however, constitute an expense item in the use of the motor, as it can be stored in an inexpensive reservoir, or cooling tower, which once charged, will last indefinitely.

The cost of operation will then be practically confined to the cost of oil, and as the motor shows itself to be able to use oil obtainable at about 2 cts. per gallon, the cost of a B. HP. may be 0.2-ct. per hour, which is slightly less than the cost of the same power from the average triple-expansion steam engine, with coal at $3 per gross ton.

◆

THE CONTRACT FOR THE COOLGARDIE STEEL PIPE LINE, WESTERN AUSTRALIA.

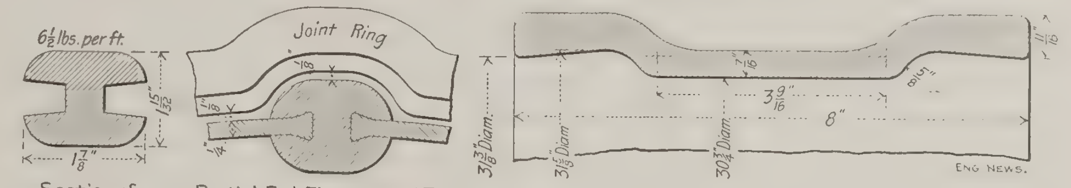
During the current year we have given considerable space to accounts of the immense steel pipe line, 30 ins. in diameter and 328 miles long, to be built by the government of Western Australia to supply water to the Coolgardie mining district.*

Through the courtesy of Mr. C. Y. O'Connor, M. Inst. C. E., of Perth, W. A., Engineer-in-Chief of the Department of Public Works of Western Australia, we are enabled to give further particulars regarding the contract and the pipe to be used in its fulfillment.

As stated in previous issues, the works as a whole include, besides the pipe line, a large storage reservoir, nine pumping stations, and a small intake reservoir at each station. The works are designed to deliver 5,000,000 (British?) gallons a day, with an aggregate lift of 1,313 ft. at the nine stations, the lifts generally being through short sections of the line, with long sections of falling grade between them.

As coal costs some $7 to $8 a ton and the total lift is so great, it is of course desirable to reduce friction to a minimum, even at a large increase in the capital outlay for the pipe line. Mr O'Connor originally planned to use 30-in. spiral riveted pipe for the whole line, but the English engineers recommended 26, 27½ and 29-in. pipe, according to the head, and that pipe of plates ¼-in. or more in thickness be made with two gas-welded longitudinal joints; and that the pipe made of 3-16-in. plates, comprising about 246 of the 330 miles, be riveted longitudinally and transversely, with sections alternately in and out. The contract as finally awarded is for pipe of a diameter of 30 ins. throughout, in 28-ft. sections, with two longitudinal locking bar joints. For the transverse joint, steel rings, or sleeves, calked with lead, will probably be used, to be furnished by the contractors at the option of the government.

Bids for furnishing the pipe f. o. b. in Western Australia, including all duties, insurance and freight, were invited at London, and also at Perth, W. A. The lowest bids received in London were, for the riveted pipe, $3,810,000, from Buchner Blagen, of Portland, Ore.;** for the welded pipe, $2,300,000, from Piggot & Co.; total, $6,100,000. The lowest bids at Perth were, for the riveted pipe, $3,325,000, from G. & C. Hoskins, of Sydney; for locking bar pipe, in lieu of welded, $1,165,000, from Mephan Fergusson, of Perth; total, $4,490,000. The engineer's estimate for 330 miles of 30-in. spiral riveted steel pipe was $5,340,000, so the lowest home bid was not only lower than the foreign bid, but lower than the estimate by $850,000. If, however, the lowest bid for welded pipe, which type was specified, had been accepted, the aggregate of the lowest bids would have been $5,625,000, or $285,000 above the estimate, the smaller size of the welded pipe not making up for its increased cost.



Section of Locking Bar from Mill.

DETAILS OF LOCKING BAR AND RING JOINTS FOR THE COOLGARDIE STEEL PIPE LINE.

After negotiations with the lowest home bidders, Messrs. Hoskins and Fergusson, it was finally arranged, and a contract executed accordingly, that the contract should be divided equally between them, the size of all the pipe to be increased to a diameter of 30 ins., and the thickness of the 3-16-in. plates, making up a large part of the contract, to be increased to ¼-in. Of the 61,856 lengths of 28-ft. pipe, 1,000 will be made from 5-16-in. plates, and the balance from ¼-in. The contractors, of course, revised their unit prices, and as the quantities were increased the aggregate of the new bids was brought up to $4,990,000, which is still $350,000 below the engineer's estimate. The contract also includes as many steel jointing rings, up to 61,856, as the government may desire, at about $5.50 each. This item was made conditional, owing to doubts as to whether these rings can be used for all joints. The original intention was to lay the pipe on the surface of the ground, but this has been abandoned, rendering unnecessary the expansion joints illustrated in our issue of Oct. 13.

The weight of the steel involved in this pipe contract, without the rings, is 74,442 long tons. The coating will add 3,867 long tons. The contract price for the coated pipe is about $65.30 per long ton, or a little under 3 cts. per lb., f. o. b. at Falkirk, W. A. The contract is dated Oct. 18, 1898. The specifications for the pipe are as follows, being identical for each of the two contracts:

(1) Quantities and Dimensions—
30,428 lengths of 28 ft. each ¼-in. thick and 30 ins. internal diameter.
500 lengths of 28 ft. each, 5-16-in. thick and 30 ins. internal diameter.
Total, 30,928 lengths of 28 ft. each.

(1) General Description of Pipes.—The pipes shall be of the type known as Mephan Ferguson's Patent Rivetless or Locking-bar Pipes, and each 28 ft. length of pipe shall be composed of not more than two plates and two longitudinal locking-bars, as shown in the drawings. Each locking-bar of the ¼-in. pipes shall weigh not less than 6½ lbs. per lin. ft., and each locking-bar of the 5-16-in. pipes shall weigh not less than 7¾ lbs. per. lin. ft., unless it shall have been conclusively proved to the satisfaction of the engineer that such weights can be reduced without any risk of impairing the efficiency of the locking-bar joint, which must in all cases be of the full strength of the plates. If, on the other hand, it be found that the weights specified are too light, or that the sections shown in the drawings are capable of improvement, then the bars shall be increased in weight or be otherwise modified as the engineer may direct.

(3) Joint Rings.—The contractor shall also supply so many welded steel joint rings of the type shown in the drawings as may be ordered, up to a total of 30,928 of such rings at the rate of £1 2s. 6d., delivered at Falkirk.

(4) Anchor Plates.—Three feet from one end of every fourth 28-ft. length, three 12-in. pieces of angle iron, 6 × 4 × ⅜-in., shall be double riveted to the pipe to prevent creep, wherever the engineer may consider that such precaution is desirable.

(5) Special Pipes.—Where required, the contractor shall provide, at the same price per foot as ordinary lengths, special lengths to connect pipes of different thicknesses of metal, so that a good joint may be made without fitting or arranging in laying the pipes, and also such tapered tubes as may be required for purposes of fitting valves of all kinds. The contractor shall also supply without extra cost such tubes as may be required for curves, with ends either not parallel to each other or not rectangular to the pipe, as the engineer may direct.

(6) Coolgardie to Kalgoorlie Pipe Main.—The contractor shall also provide, if required, half the quantity of pipes necessary for a water main from Coolgardie to Kalgoorlie at the same rate per ton as his contract price per ton for the pipes of 30 ins. diameter and ¼-in. thick, herein provided for. The diameter of such main has not yet been determined upon.

(7) Quality of Steel.—The plates and bars shall be made of open hearth acid steel and the plates shall be capable of withstanding a tensile strain of not less than 25 tons [N. B.: All tons are long tons here.—Ed.] nor more than 2 tons per sq. in., with elongation in 10 ins. of not less than 20%, and contraction of area of not less than 45%. The steel must also resist the following drifting test, that is to say: A hole ⅝-in. diameter to be punched within 1¼ in. of any edge of a plate and to be drifted out

---

*Heat of combustion accounted for by indicated power.

*See Eng. News, Feb. 10, 1898, for a description of the scheme, and a profile of the pipe line; Feb. 17 and Oct. 13, 1898, for editorial discussions of the pipe line, including the recommendation of the English engineers, who reported on it; and Nov. 17, 1898, for a brief note on the award of the contract.

**But the bid was for basic, instead of acid, steel, and for punched, instead of drilled rivet holes.

cold to a diameter of 1⅛ in. without showing signs of fracture. It must also resist such hot and cold bending tests as the engineer may consider necessary to assure him that the steel is of the best quality and perfectly suitable for the work. The manufacturers of all steel employed on the work must be previously approved in writing by the engineer.

(8) Testing of Steel.—Each plate on leaving the rolls shall be stamped with its cast number or with consecutive numbers which will identify the cast. A mill sheet giving cast numbers and size of each plate shall be supplied every morning to the authorized representative of the engineer, who will then select pieces for tests of tensile strength. Not less than two tensile tests will be made from each cast, and bending and drifting tests will be made from each plate, and the pieces must bend cold round a bar of a diameter of three times the thickness of the plate, without signs of fracture. Pieces must be sheared for the purpose of testing and duly marked with the plate number. Should the test pieces fail to withstand any of the specified tests, the whole cast represented will be liable to rejection.

(9) Testing of Locking-Bar.—Sections of locking-bar and adjacent plates, shall be cut from any such pipes as the engineer may direct and such sections shall be submitted to tensile strain for testing the efficiency of the locking-bar joint, which must be capable of withstanding without injury a strain equivalent to 29 tons per sq. in. of plate, unless the plate itself fail within the limits of 25 and 29 tons per sq. in. specified for such plates, but the joint must be always fully as strong as the plate and shall safely resist all strains within the limits above mentioned.

(10) Method of Manufacture.—The pipes shall be made strictly to the drawings and shall be as nearly circular as possible. The thickness of plates specified are those of the thinnest parts of the plates. Every plate will be measured, and all will be rejected in which the thickness of any part falls in the least degree below that specified. The workmanship throughout shall be the best possible.

(11) Calking.—No calking of the locking-bar joint will be permitted.

(12) Protection of Plates and Bars.—All plates and bars which may be imported into the Colony by the contractor shall be carefully protected against oxidisation, and all plates and bars which have become unduly rusted will be rejected, and shall be forthwith removed from the works.

(13) Dipping of Bars and Edges of Plates.—Before the locking-bar joints are made the locking-bars and the outer portions of the plates shall be completely freed from black oxide, by being dipped in a bath of dilute sulphuric acid and then in a bath of limewater, followed by scrubbing if necessary. This must be done under cover, and the plates and bars must not be exposed to the weather after dipping, but must be at once formed into pipes.

(14) Pressure Test.—The pipes shall then be submitted to hydraulic pressure of 400 lbs. to the sq. in., and also to smart tapping with a hammer while under pressure. All pipes which leak, or show other defects, shall be rejected, or the defects remedied in such manner as may be approved by the engineer.

(15) Dipping of Pipes.—After having been tested and approved by the engineer, the pipes shall be dipped in a bath of dilute sulphuric acid and then in a bath of limewater, and shall, when thoroughly clean, be forthwith coated.

(16) Coating.—The pipes shall be coated with a composition, consisting of Trinidad asphaltum and creosote as soon as they have been freed from black oxide, and otherwise thoroughly cleansed, as specified in Clause 15 above. They must be heated uniformly before being immersed to about 300°F., and the bath of composition must be kept fluid at an uniform temperature. They must be left in the asphaltum bath long enough to acquire the same temperature as the bath, and then suspended until the excess of coating has drained off. Very special care must be taken in coating the pipes, and the whole of the arrangements, as well as the composition of the asphaltum mixture, must be to the entire satisfaction of the engineer.

(17) Place of Delivery.—The pipes, special pipes and joint rings, etc., shall be delivered on land belonging to the Government, at Falkirk, Western Australia, and shall, after having been finally passed by the engineer, be stacked on a piece of land belonging to the Government, and reserved for the purpose, so that they may be kept apart from those which have not yet been passed.

(18) Special Pipes Testing and Treatment.—All special pipes provided for in this specification shall be tested and treated in a similar manner to the 28-ft. lengths of pipes.

(19) Joint Rings Testing and Treatment.—The materials of which the joint rings are to be constructed shall, as far as practicable, be subject to similar tests, and shall be treated in a similar manner to the materials of which the pipes are to be constructed.

The designs for the locking-bar for the longitudinal joints and the steel rings for the transverse joints are shown in the accompanying illustration. The only work on which this locking-bar has been used heretofore, so far as we can learn, was for 8¾ miles of 15 and 26-in. pipe connected with the water supply of Adelaide, S. A., as described in our issue of June 9, 1898. Editorial comment on the contract is made elsewhere in this issue.

WEATHER TABLE FOR NOVEMBER, 1898. (Furnished to Engineering News by the Department of Agriculture.)

BOOK REVIEWS.

U. S. GEOLOGICAL SURVEY.—Bulletin No. 88: The Cretaceous Foraminifera of New Jersey. By Rufus Mather Bagg, Jr.; pp. 71. No. 89: Some Lava Flows of the Western Slope of the Sierra Nevada, California. By F. Leslie Ransome; pp. 74. No. 149: Bibliography and Index of North American Geology, Paleontology, Petrology and Mineralogy for the Year 1896. By Fred. Boughton Weeks; pp. 152. Washington, D. C. Paper; 9 × 6 ins.; the first two illustrated.

REPORT RESPECTING THE YUKON DISTRICT.—By Major G. M. Walsh, Commissioner, Department of the Interior, Ottawa, Canada. Ottawa. Paper; 9¾ × 6½ ins.; pp. 28.

This report covers the food question, royalty to the government, mail service, liquor dealing, law and order, river navigation, mining regulations, output of gold, general prospects, etc., in the gold producing region of Canadian Alaska. Maj. Walsh figures the output of gold for 1898 at about $10,000,000, and thinks that the Klondike will be a rich mining camp for the next 25 years. In the summer of 1898 from 3,000 to 5,000 people went up the Stewart River; but very little intelligent work seems to have been done. The trade of the camp is worth about $8,000,000, and in ten years it should be worth $30,000,000, and he calls the attention of Canadians to this fact.

NOTES ON THE NICARAGUA CANAL.—By Henry I. Sheldon. New and enlarged edition. Chicago: A. C. McClurg & Co. Cloth; 8½ × 5½ ins.; pp. 242; illustrated. $1.25.

As the author explains in his preface, this is a popular, and not a technical or professional discussion of the Nicaragua Canal project, and his avowed purpose is to stimulate popular interest in the enterprise. He believes that the tardy development and depressed agricultural interests of California, Oregon and Washington, are due to their long distance from markets and that a ship-canal through the Isthmus can alone benefit them. His visit to Nicaragua was made in 1895, and the lack of facilities made it impossible for him to visit the actual line of the canal between Greytown and Ochoa; though he did ride over the line between the Lake and the Pacific. All engineering data he obtained from the records of the Maritime Canal Co., in which he evinces entire faith, and from the report of the Ludlow Commission. The real interest of the work therefore lies in Mr. Sheldon's observations upon the people and resources of Nicaragua; the climatic conditions he found; the expenses of traveling and living, etc. These parts are useful to the intending traveler and are interesting to the general reader. Mr. Sheldon considers the conditions in Nicaragua very favorable to canal building. Notes upon other great ship-canals follow, based mostly upon personal inspection in 1897, and he gives an interesting general history of the Suez, Manchester, Chicago Drainage, Panama and North Sea-Baltic ship-canals. The discussion as to probable revenue and cost, method of construction and operation, etc., is very brief, and while the author evidently aims to be judicial, his enthusiasm rather carries him off his feet. For example, he thinks one great reason for building the canal is the trade of the Philippines, although the difference in the distance from New York to Manila by Suez and by Nicaragua, will be only 600 miles in favor of the latter, and the possibility of more frequent coaling on the Suez route would probably overbalance the difference in distance. Again, he says that the Nicaragua Canal will make New York and Liverpool "almost equally distant from Hong Kong," whereas as a matter of fact it will be no shorter voyage from New York to Hong Kong by Nicaragua than the present route via Suez. The book is written, however, in an entertaining style, and will doubtless find many readers.

ELEMENTS OF SANITARY ENGINEERING.—By Mansfield Merriman. Professor of Civil Engineering in Lehigh University. New York: John Wiley & Sons. London: Chapman & Hall, Cloth; 6 × 9 ins.; pp. 216; illustrations. Price, $2.00.

After an introductory chapter on "Sanitary Science," the author takes up in succession "Water and Its Purification;" "Water Supply Systems;" "Sewerage Systems;" and "Disposal of Garbage and Sewage." As an elementary work on sanitary engineering, adapted more especially for college use, the book is an excellent one. It outlines in a satisfactory manner the several branches of sanitary engineering named in the chapter headings, and so emphasizes the most important principles that they are pretty sure to be impressed upon the minds of the reader or student.

An excellent feature of the volume is a list of topics for further investigation at the end of each chapter. These not only point the way to specific sources of information, but, if followed out, cannot fail to broaden the minds of the investigators, by showing the connection between this and other branches of science, and by bringing the reader in contact with some of the best things in general literature. To illustrate the latter point, there is a reference to Charles Reade's "Put Yourself in His Place," for a description of the failure of the Dale dyke reservoir, near Sheffield, England, in 1861, and to Goethe's "Faust," for the reflections of the latter on his work in sanitary engineering.

It may cause surprise to some to know that the heating and ventilation of buildings is not given a chapter. The reason for not doing this, the author states, is that while these subjects are in the domain of sanitary science they do not pertain to the work of the sanitary engineer, which relates to matters affecting the public rather than the individual; also, that the architect, and not the engineer, is responsible for heating and ventilation. We believe there are many who will not agree with this line of reasoning, or who will at least feel that the ventilation of buildings is quite as much a public matter as the plumbing they contain, which receives attention in the book. The statement that the subject of ventilation has been adequately presented in other books, is hardly a reason for not taking it up here, as there is little on any subject in the volume before us that has not been treated much more fully elsewhere. In the section on "Water Supply," the author goes into hydraulics and hydromechanics to a rather surprising extent in a book on sanitary engineering. The subject of garbage disposal, on the other hand, might well have been discussed with greater fullness. The book has no index, a surprising omission to be made by an author with such a large experience, both as a teacher and a writer, and one which should be remedied in the future editions. Despite these minor defects, the book, as we have said above, is calculated to fill a real need as an elementary general textbook in this field.

PERSONAL.

Capt. F. P. Brevier has been appointed Superintendent of the water-works of Mobile, Ala.

Mr. Gavin Nelson Houston, Jun. Am. Soc. C. E., formerly Assistant Engineer, has been appointed Superintendent of Water-Works of Nyack, N. Y., to take effect July 1.

Mr. William D. Cornish, of St. Paul, Minn., has been elected First Vice-President of the Union Pacific R. R., with headquarters in New York city, to succeed Mr. Oliver W. Mink, resigned.

Mr. A. A. Wirth has been appointed Assistant Engineer of Maintenance of Way of the Pennsylvania Lines West of Pittsburg, with headquarters at Louisville, Ky., to succeed Mr. William B. Blake, promoted.

Mr. Thomas B. Minister has been appointed Superintendent of Buildings of the Borough of Brooklyn, New York city, to succeed Mr. John Guilfoyle, whose appointment as Commissioner of Buildings was noted in our issue of June 9.

Mr. Bushrod W. Taylor, Engineer of Maintenance of Way of the Pennsylvania Lines West of Pittsburg, has been appointed Superintendent of the Louisville Division, with headquarters at Louisville, Ky., to succeed Mr. P. A. Bonebrake, transferred.

Mr. William B. Blake, Assistant Engineer of Maintenance of Way of the Pennsylvania Lines West of Pittsburg, has been appointed Engineer of Maintenance of Way, with headquarters at Louisville, Ky., to succeed Mr. Bushrod W. Taylor, promoted.

Mr. Charles S. Butts, civil engineer, is making a resurvey with a complete set of maps of the Lake Superior & Ishpeming Ry., with headquarters at Marquette, Mich. He was recently engaged on similar work on the Lake Erie & Western R. R., with offices at Indianapolis, Ind.

Mr. P. A. Bonebrake, Superintendent of the Louisville Division of the Pennsylvania Lines West of Pittsburg, with offices at Louisville, Ky., has been appointed Superintendent of the Indianapolis Division, with headquarters at Columbus, O., to succeed Mr. Frank G. Darlington, M. Am. Soc. C. E., resigned.

Mr. Dorsey Ash, who has been employed by the Metropolitan Water Board of Massachusetts on the construction of the Washusett Aqueduct, has resigned to take charge of the construction of a fortification and gun emplacements at Grover's Cliff, Winthrop, Mass., under Lieut.-Col. Mansfield, Engineer Corps, U. S. A.

Mr. Emil Swensson, M. Am. Soc. C. E., Chief Engineer and Superintendent of the Keystone Bridge Works, Carnegie Steel Co., Ltd., Pittsburg, Pa., was tendered a dinner, June 30, by the heads of the company's departments just prior to his sailing for Sweden, of which he is a native, after 18 years spent in the United States.

Mr. Nelson D. Miller has been appointed Chief Engineer of the Great Northern Ry., with headquarters at St. Paul, Minn., to succeed Mr. John F. Stevens, M. Am. Soc. C. E., whose resignation was noted in our last issue. Mr. Miller resigned the above position Jan. 7, 1895, to take charge of the engineering work on the Kaslo & Slocum Ry., then under construction.

Prof. William Dennis Marks, M. Am. Inst. E. E., President of the American Electric Meter Co., Philadelphia, Pa., has been elected President of the General Electric Automobile Co. of the same city. He was Professor of Dynamical Engineering in the University of Pennsylvania for a number of years. In 1887 he became engineer of the Edison Electric Light Co., of Philadelphia, and in 1889 was made Chief Engineer, and later President, of the Edison General Electric Lighting Co.

OBITUARY.

Mr. J. R. Kerr, Resident Engineer of the new waterworks at Augusta, Ga., died June 29.

Mr. Palmer J. Pillans, for many years City Engineer of Mobile, Ala., died June 22, aged 83.

Mr. Edward Gustine, contractor for water and gas works, of Keene, N. H., died July 4, aged 78.

ENGINEERING SOCIETIES.

COMING TECHNICAL MEETINGS.

INTERNATIONAL MINING CONGRESS.
July 6-9. At Salt Lake City. Secy., W. D. Johnson, Salt Lake City, Utah.
MONTANA SOCIETY OF ENGINEERS.
July 9. Secy., A. S. Hovey, National Bank Bldg., Helena, Mont.
CIVIL ENGINEERS' CLUB OF CLEVELAND.
July 12. Secy., Wm. H. Searles, Case Library Bldg., Cleveland, O.
AMERICAN SOCIETY OF R. R. SUPERINTENDENTS.
July 13-14. Annual meeting, Alexandria Bay, N.Y. Secy., C. A. Hammond, Asbury Park, N. J.
AMERICAN HEATING AND VENTILATING SOCIETY.
July 15. Atlantic City, N. J. Secy., S. A. Jellett, 704 Arch St., Philadelphia, Pa.
ENGINEERS' CLUB OF MINNEAPOLIS.
July 18. Secy., H. E. Smith, 1620 S. E. 4th St., Minneapolis, Minn.
ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.
July 19. Secy., R. A. Fessenden, 410 Penn Ave., Pittsburg, Pa.
WESTERN FOUNDRYMEN'S ASSOCIATION.
July 20. Secy., B. M. Gardner, 1522 Monadnock Block, Chicago, Ill.
AMERICAN SOCIETY OF CIVIL ENGINEERS.
July 26 to 29. Annual convention at Detroit. Secy., C. W. Hunt, 220 W. 57th St., New York, N. Y.
WESTERN SOCIETY OF ENGINEERS.
Aug. 3. "Establishment of Street Grades," Chas. P. Chase. Secy., N. L. Litten, Monadnock Block, Chicago, Ill.
SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.
Aug. 18 to 20. Annual meeting at Massachusetts Institute of Technology, Boston, Mass. Secy., Albert Kingsbury, Durham, N. H.

PACIFIC COAST ELECTRICAL TRANSMISSION ASSOCIATION.—At the annual meeting of the Association held June 21 the following officers were elected for the ensuing year: President, W. Frank Pierce; Vice-President, Carrol M. Beal; Secretary, Geo. P. Low, and Treasurer, William Angus.

MONTANA SOCIETY OF ENGINEERS.—At the regular monthly meeting held June 11 Mr. Walter Harvey Weed, U. S. Geologist, delivered a lecture upon the geology of Butte, Mont. The lecture was illustrated by maps showing the various geological formations in and about this important mining center.

ENGINEERING ASSOCIATION OF NEW SOUTH WALES.—At the regular meeting of the Association, held at Sydney, May 12, Mr. F. Ernest Stowe read a paper entitled "Instrumental Calculations as Applied to Modern Engineering." The paper dealt with the application of the slide rule in various forms to the calculation of the horse power of engines and the various other quantities and forces used in engineering work.

INTERNATIONAL MINING CONGRESS.—The annual meeting of this organization is to be held at Salt Lake City, Utah,on July 6 to 9 inclusive. The programme as announced includes besides the routine business and a long list of entertainments and excursions two special committee reports, one regarding the establishment of a national department of mines, and the other regarding the revision and codification of the Federal mining laws,and the following special papers: "Coal and Coke," "Advances in Methods of Concentration.," "Relation of the Geological Survey to the Mining Industry," "Relative Merits of Cyaniding and Chlorination," "Mine Inspection," "History of Reduction of Smelting Costs," "Long Distance Transmission of Electric Power," "Fuel Cost in Pumping," "Recent Advances in Smelting," "A New Treatment of Low Grade Ore," "Copper," "Relations of Investors and Miners."

IRON AND STEEL INSTITUTE OF GREAT BRITAIN.—The following special transportation arrangements have been made for the members leaving England to attend the autumn meeting of the Institute to be held at Stockholm on Aug. 26 and 27:

A special steamer of over 3,000 tons will be sent by Dr. H. S. Lunn and Mr. Woolrich Perowne on an itinerary to suit the exact requirements of the members. This vessel will leave Newcastle-on-Tyne on Aug. 17, and will proceed by way of the Baltic Canal, Kiel and Wisby to Stockholm, where she will lie, and serve as a floating hotel, from Aug. 25 to Aug. 28. The return journey will be by way of Copenhagen, Gothenburg and Christiania. The cruise will occupy 19 days, and the fare will be nineteen guineas for berth in four-berth cabins. Dr. Lunn and Mr. Perowne have also arranged for the steamship "St. Sunniva," a 1,000-ton boat, to leave Leith on Saturday, Aug. 20, proceeding by way of Christiania to Stockholm, where she will lie Aug. 26, 27 and 28, proceeding from Stockholm to St. Petersburg, and returning by way of Copenhagen and the Baltic Canal. This cruise will take 24 days, and the fare will be 20 guineas each passenger in four-berth cabins; 25 guineas each passenger in two-berth cabins; and 35 guineas for the exclusive use of a two-berth cabin by one passenger. The Orient Steam Navigation Co., Ltd., have also rearranged the itinerary of their pleasure cruise No. 3 to the Baltic, so as to bring their steamship "Lusitania" (3,912 tons) to Stockholm on Aug. 25, and to keep her there until Aug. 28. The itinerary includes visits to Copenhagen, Wisby, Stockholm, Kronstadt, St. Petersburg, Kiel, and the Baltic Canal, and occupies 28 days, from Aug. 17 to Sept. 14, the fares being from 35 guineas exclusive of shore excursions, or from 55 guineas inclusive of shore excursions. Particulars of this cruise can be obtained from Messrs. Anderson, Anderson & Co., No. 5, Fenchurch Ave., London, E. C. Particulars of the other cruises can be obtained from Dr. H. S. Lunn, No. 5 Endsleigh Gardens, London, N. W.

NEW PUBLICATIONS.

PROCEDURES RECOMMENDED FOR THE STUDY OF BACTERIA, with Especial Reference to Greater Uniformity in the Description and Differentiation of Species. Being the Report of a Committee of American Bacteriologists to the Committee on the Pollution of Water Supplies of the American Public Health Association. Submitted at the Meeting of the Association in Philadelphia, Pa., September, 1897. Paper; 6 × 9 ins.; pp. 47; illustrations and folding sheets giving forms for reports. Address any member of committee as follows: J. Geo. Adami, Chairman, McGill University, Montreal, Que.; A. C. Abbott, University of Pennsylvania, Philadelphia; T. M. Cheesman, College Physicians and Surgeons, New York city; Geo. W. Fuller, Bacteriologist to Commissioners of Water-Works, Cincinnati, O.; W. T. Sedgwick, Massachusetts Institute of Technology, Boston; Chas. Smart, U. S. Army, Washington, D. C.; Theobald Smith, Harvard University, Cambridge, Mass.; W. H. Welch, Johns Hopkins University, Baltimore, Md.

The general scope of this report is fully given in the title. While we do not pretend to pass judgment upon matters relating almost wholly to bacteriological methods we have no hesitation in saying that the names of the men composing this committee are in themselves a guarantee of the value of the report and that just this sort of co-operative work was needed and gives every promise of being highly beneficial. Recent progress in checking the spread of disease through water and sewage purification, disinfection and other means of prevention is largely indebteded to bacteriology and will so continue. Engineers stand ready to do whatever biologists point out as necessary in the line of public sanitation. Bacteriology is so new an art and so many workers of all classes of ability have taken it up that there is great need of co-operative work to place the methods followed and the results obtained on a truly scientific basis.

The over-zealous, to use the most charitable term available, must be repressed, especially in naming new species and announcing the isolation of typhoid germs from drinking water, and the careless and unmethodical must be urged to do better work.

THE TECHNOGRAPH, 1897-98.—Published annually by the Association of Engineering Societies of the University of Illinois; Champaign, Ill. Paper; 8vo.; pp. 146; illustrated; 50 cts.

The first paper in this number of "The Technograph," while addressed principally to architects, should be of interest to many engineers. It is entitled "Notes on Sketching," and shows the value of the ability to make a sketch, not necessarily artistic, but one which will be of use as an aid to memory if for nothing else. The introduction of amateur photography has tended to kill the art of sketching, but there are many matters of detail, which no photograph can show satisfactorily. Many of the private note books of the older engineers are full of valuable sketches giving information which could be given in no other way.

The other papers include "Standard Methods of Testing Paving Brick," and "The Shearing Strength of Rivet Steel," both by Prof. A. N. Talbot; "The Effects of Temperature on Insulating Materials" and "Electric Car Heaters," both by Prof. W. Esty; "The Buildings of the Electrical and Mechanical Engineering Laboratory," Prof. S. J. Temple; "The Design of Elevating and Conveying Machinery," J. V. E. Schaefer; "The Effect of Freezing Cement Mortar,"A. C. Hobart; "The Central Heating, Lighting and Power Plant of the University of Illinois," Prof. L. P. Breckenridge; "Strength of Concrete of Various Proportions," R. B. Ketchum and F. W. Honens; "Specification Writing," Prof. J. M. White; "The Corrosion of Iron," Prof. S. W. Parr and A. E. Paul; "Survey of a Deep Coal Mine in Illinois,' W. H. Tarrant; "Repairing Plaster of Paris Casts," C. R. Clark; "Repairs of Masonry Arch; Illinois Central R. R.," A. E. Harvey; "A Problem in Metallurgy," W. H. Kavanagh; "Simple Standard for the Precision of Level Circuits," Prof. Wm. D. Pence; "Impact Tests of Beams," D. C. Wray; "A Governor Indicator," A. H. Neurother; and "A Short Method for Railway Crossing Computations," L. K. Vial and R. B. Ketchum.

TRADE PUBLICATIONS.

(The standard sizes for pamphlets and trade catalogues recommended by all the principal engineering societies of the United States are: 3 1-2 x 6 ins.; 6 x 9 ins., and 9 x 12 ins.)

SOME LIGHTING PLANTS.—Walker Co., Cleveland, O. Pamph.; 10¼ × 7½ ins.; illustrated.

This pamphlet gives nine full-page half-tone illustrations of isolated plants using Walker apparatus. A brief description accompanies each picture.

VOLTMETERS, AMMETERS AND WATTMETERS.—Whitney Electrical Instrument Co., Penacook, N. H. Pamph.; 6 × 3¾ ins.; pp. 80; illustrated.

This small pamphlet tells about the electrical instruments manufactured by the Whitney Electrical Instrument Co.

STEAM AND OIL SEPARATORS.—The Cochrane Separator, Harrison Safety Boiler Works, Philadelphia, Pa. Pamph.; 5¾ × 7½ ins.; pp. 48.

The well-known Cochrane separator is now made in a great number of sizes and of different shapes. One recently built was 13 ft. high and 5 ft. in diameter. The pamphlet illustrates all the styles.

STREET IMPROVEMENTS AND GENERAL CONTRACTING.—City Street Improvement Co., Mills Building, San Francisco. Paper; 9 × 7 ins.; not paged; illustrated.

Most of this pamphlet is given up to a description of bituminous sand-rock paving materials and the bituminous rock mines of this company located in San Luis Obispo, Monterey and Santa Cruz Cos., Cal. Most of the balance is devoted to a detailed list of the paving, sewer and other contracts executed by the company. An illustrated description of the Humboldt Bay Jetty System at Eureka, Cal., occupies two pages. This work was begun April 15, 1893, and it is expected that it will be completed next year. The above-named company has the contract. The government appropriation for the work was about $1,740,000.

SIGNAL AND INTERLOCKING PLANT. — National Switch & Signal Co., Easton, Pa. Paper; 7 × 10 ins.; pp. 35.

This beautifully printed pamphlet is a compilation of descriptions of certain devices and plants which have been published in the technical papers. It includes the interlocking plant of the State Line crossing, the use of the train-staff system for block working at single-track tunnels on a double-track road, and the electric block and mechanical release, as described in our issues of Jan. 20, Feb. 24 and May 12, respectively. There is also an article showing that under the electric train-staff system back flagging is not required.

WHITE-LEAD, PAINTS AND CHEMICALS.—Harrison Bros. & Co., Philadelphia, New York and Chicago. Boards; 9 × 6 ins.; pp. 96.

The historical review in this catalogue is a very interesting sketch of the growth of a great manufacturing establishment founded in 1793 by Mr. John Harrison, of Philadelphia. Mr. Harrison was the first maker of sulphuric acid in the United States, the first to concentrate the acid in platinum instead of glass retorts, and the first but one to make white-lead in this country. The works of this company have grown from the small establishment of 1793 to one covering 35 acres of ground at Gray's Ferry, in Philadelphia. The catalogue itself describes and prices the products of the present company. These include white-lead for various purposes, zinc white, the "Harrison" oil colors, paste oil colors, coach paints, distemper or fresco colors, stains, varnishes, dry paints, etc. Included with this pamphlet is another on the "Chemistry of Paints," which gives a very good idea of the methods of making paints and chemicals and concludes with a very practical treatise on the application of paints.

RAILWAYS.

ARKANSAS, LOUISIANA & SOUTHERN.—F. H. Drake, Pres., Minden, La., informs us that track is now being laid on this proposed line and that it is expected to run a through train soon on the road. The route is from Sibley, La., on the Vicksburg, Shreveport & Pacific R. R., to Stamps, Ark., a distance of 65 miles. M. M. Hunt has part of the contract work. L. N. Polk, Ch. Engr., Minden.

BRIDGEPORT & HELENA.—This company has been incorporated in Oregon, with a capital stock of $5,000,000, to construct a railway from Bridgeport, Ore., to Helena, Mont.

BRITISH COLUMBIA.—Press reports state that Mackenzie & Mann, Toronto, Ont., have accepted the subsidy of $4,000 a mile from the province of British Columbia, and have signed a contract by which they agree to commence work at once on the proposed line of railway from Glenora to Lake Teslin. It is said that the country is quite level, and that no engineering difficulties of any magnitude will be found.

CENTRAL R. R. OF WEST VIRGINIA.—This company was incorporated in West Virginia June 29, with headquarters at Morgantown, W. Va., with a capital stock of $100,000, to construct a steam railway to connect Morgantown and Charleston, W. Va., a distance of about 130 miles. The incorporators are Thos. E. Davis and Geo. M. Whitescarver, of Grafton, W. Va.; R. T. Devries, Wheeling, W. Va.; Geo. C. Sturgis, Morgantown, W. Va.; J. W. Mason, Fairmont, W. Va.

CHICAGO GREAT WESTERN.—This company is reported to have awarded the following contracts: For changing four miles of grade at Kenyon, Minn., to William Stoddard, of St. Paul, Minn., at $20,000; for improving station grounds at Hayfield, Minn., and for 1½ miles of siding, to cost $12,000; for filling in three miles of wooden bridges, to cost $300,000; for seven stone culverts, to cost $25,000, to John Nevin & Son, St. Paul. H. Fernstrom, Ch. Engr., St. Paul.

CHICAGO, INDIANA & EASTERN.—The sections of this proposed railway from Swayzee to Converse, Ind., seven miles, and from Matthews to Muncie, Ind., 15 miles, are said to be under construction. H. U. Drew, Gen. Mgr., Fairmount, Ind.

CHICAGO, ROCK ISLAND & PACIFIC.—B. B. Brayton, Davenport, Ia., informs us that the Flick & Johnson Construction Co., of Davenport, has completed about one-half of the construction work on that portion of the line between Davenport and West Liberty. The work includes about 35 miles of grading for double track; the erection of iron girders and pipe culverts; masonry work and concrete piers and abutments, etc. The bridges include two double-track lattice bridges, 126 ft. long; four pairs of 44-ft. deck-plate girders; and three pairs of 33-ft. girders. It is expected to complete the work by September 15. W. G. Purdy, Chicago, Ill., Pres.; W. K. McFarlin, Supt. Maintenance and Construction, Davenport.

CHICAGO, ROCK ISLAND & TEXAS.—H. A. Parker, Vice-Pres. Chicago, Rock Island & Pacific Ry. Co., Chicago, Ill., informs us that nine miles of track were laid on June 28 on this proposed line of railway from Bridgeport to Jacksboro, Tex. It is expected to reach Jacksboro, 29 miles from Bridgeport (on the main line), by August 1. Pres., M. A. Law, Topeka, Kan.; Ch. Engr., W. B. Worrell, Bridgeport, Tex.

COLUMBUS, FULTON & NORTHERN. — Newman Cayce, Pres., Columbus, Miss., informs us that the larger part of this line has been surveyed and much of the right of way been obtained, but that no contracts have yet been offered. The proposed route is from Columbus, Miss., to Lexington, Tenn., via Aberdeen, Amory, Fulton, Burnsville and Savannah, a distance of 175 miles.

DETROIT & LIMA NORTHERN.—Reports state that track has been laid on this new road between St. John's and Bellefontaine, O., about 20 miles. This is a portion of the proposed extension of the Columbus & Northwestern from St. Mary's to Peoria, via St. John's and Bellefontaine, 50 miles. D. J. Casey, Ch. Engr., Bay City, Mich.

DULUTH & NORTHERN MINNESOTA.—Grading is said to have begun on the first six miles of this new logging railway from a point on Lake Superior north to open up the lumber district of St. Louis and Lake counties, controlled by Alger, Smith & Co., lumbermen, of Detroit, Mich. Preliminary surveys have been made for about 30 miles, and it is intended that the work of laying 60-lb. rails, with a standard gage, be done by the company direct. Pres., M. S. Smith, Detroit, Mich.; Gen. Mgr., John Millen, Black River, Mich.

INTEROCEANIC OF MEXICO.—Press reports from Mexico state that E. V. Sedgwick, Supt. of Motive Power, is in the market for ten locomotives and 1,000 freight cars. It is expected that the contracts for all this equipment will be placed some time this month from Mr. Sedgwick's office at the City of Mexico.

KANSAS CITY, ELDORADO & SOUTHERN.—Reports state that this company has executed a first mortgage to the Lincoln Trust Co., of St. Louis, for $450,000, to be used in completing the line. We have been advised that all the grading has been done and that the rails, ties, steel for bridges, etc., necessary to complete the line are upon the road. The contract is held by the Middle States Construction Co., Rialto Bldg., St. Louis, Mo., of which B. A. Aldrich is secretary.

KANSAS, OKLAHOMA CENTRAL & SOUTHWESTERN.—Press reports state that the directors of this company have awarded a contract to Coons & Co. for building the road from Bartlesville to Vernon, Tex. It is proposed to construct a railway from Cherryvale, Kan., to Vernon, Tex., through the central part of Oklahoma, a distance of about 350 miles. The Toledo Construction Co., of Toledo, O., has contracted to build a portion of the line. J. H. Bartles, Pres., Bartlesville, Ind. Ter.; F. B. Dallon, Ch. Engr., Independence, Kan.

LITTLE COAL RIVER.—The Little Coal River R. R. & Mining Co. was incorporated in West Virginia June 29, with a capital stock of $1,400,000, to construct a steam railway from St. Albans to Madison, W. Va., about 25 miles. The incorporators are H. J. Tondy, Huntington, W. Va.; J. P. Laflin, J. O. Lee, H. M. Green and A. R. Sheffer, all of New York.

MANISTIQUE & NORTHWESTERN.—C. E. Kelso, Secy., Manistique, Mich., informs us that rails have been purchased for an extension of this line from Scott's Camp to the Duluth, South Shore & Atlantic Ry.

MANSFIELD SHORT LINE.—Chas. W. French, Pres., Mansfield, O., informs us that the Crouch Construction Co., First National Bank Bldg., Chicago, Ill., which is building this line, has completed about five miles of grading, and that it expects to begin track-laying in August. The proposed route is from Shelby to Lucas, via Mansfield, O., 20 miles. Surveys have been made and the right of way is being secured. R. E. Harwood, Ch. Engr., Mansfield, O.

MISSISSIPPI, HAMBURG & WESTERN.—L. A. Cole, Pres., 100 William St., New York, informs us that ten miles of work have been completed on this new railway between Hamburg and Leland, Ark., on the Mississippi River, a distance of 40 miles. All the right of way has been obtained and the necessary capital secured. C. M. Gibson, Ch. Engr., Portland, Ark.

MONTEREY & MEXICAN GULF.—A. Monnom, Gen. Mgr., Monterey, Mexico, writes us that this company is in the market for six freight engines, three cabooses and 100 box cars of 60,000 lbs. capacity.

NORTHERN PACIFIC.—The contract for grading, bridging and ironwork on the Northern Pacific Ry. extension from Belmont to Hartney is said to have been awarded to J. D. McArthur, of Winnipeg, Man.

PACIFIC & ARCTIC.—John Hislop, Asst. Ch. Engr., Skaguay, Alaska, writes us that the Pacific & Arctic Ry. & Navigation Co. is now building a narrow gage (3 ft.) railway from Skaguay to navigable water on the Yukon. About 6,000 ft. of track is laid and four miles of grading completed and ready for track-laying. The location of the line will soon be completed to the summit of White Pass, and it is expected that trains will be running to Summit Lake or beyond in September. The work is being done by the Pacific Contracting Co., Dexter, Horton & Co., Bank Bldg., Seattle, Wash., and of which E. C. Hawkins is chief engineer and superintendent. The railway company was incorporated in West Virginia, March 27, with a capital stock of $1,000,000, by D. N. Rowan and G. W. Rowan, of Irvington, N. Y.; Webster Gillette, of New York, and others.

PONTOTOC & STARKVILLE.—This company has been incorporated at Mississippi to construct a railway from Pontotoc south to Starkville, 60 miles. It will practically be a continuation of the Gulf & Chicago line running from Middleton, Tenn., to Pontotoc, a distance of 62 miles. The building of this railway will give Memphis a shorter route to West Point, Columbus and other Mississippi towns via the Southern & Kansas City, Memphis & Birmingham lines, the Gulf & Chicago, and the proposed Pontotoc & Starkville Ry., and will open up a rich country in northeastern Mississippi.

ST. LOUIS, SILOAM & SOUTHERN.—It is announced that Hector D. Mackay, of St. Louis, Mo., who is the chief promoter of this proposed railway, has made all financial arrangements to construct the line at once from St. Louis to Fort Smith, Ark., a distance of about 300 miles, with a branch from Little Rock, Ark., to Pomona, Mo. The route has been surveyed and the line located. The International Construction & Improvement Co., of Fort Smith, Ark., which has the contract for building the road, was incorporated in Arkansas, June 24, with a capital stock of $1,000,000, by Jesse French, John L. French, H. D. Mackay, John Dooley and J. S. Drake.

SPRINGFIELD, LITTLE ROCK & GULF.—Reports state that Governor Jones, of Arkansas, has issued a proclamation annulling the Smith railway act passed June 26, 1896, which granted to this road 1,000 acres of state land, a mile for each mile of the main line and its branches that might hereafter be constructed, provided that the railway shall be completed to Fourche, La., Favre River, within twelve months from date of passage of the act. P. L. Dougherty, Ch. Engr., Springfield, Mo.

TALLAHASSE & SOUTHEASTERN.—The Florida Construction Co. is said to have 280 men at work constructing this proposed railway from Tallahassee to Gainesville, Fla. Grading is completed from Tallahassee to about Perry, and it was expected to begin track-laying on July 1, and to push the work as much as possible. R. L. Bennett, Vice-Pres., Tallahassee, Fla.

TEMPLE & SALADO.—Preliminary surveys are about completed for a line of railway between Temple and Salado, Tex., and it is said that a firm of railway contractors have made a bid to construct the 16 miles of road and to equip it with one full passenger train for $70,000.

TIONESTA VALLEY.—Crage & Tench, 61 Terrance, Buffalo, N. Y., have been awarded the contract for constructing the proposed Millstone extension of this line, which is in operation from Sheffield, Pa., south through a large timber territory. Work will begin at once. Pres., J. H. Horton, Sheffield.

MARSHALL, TIMPSON & SABINE PASS.—We are informed that the survey has been completed and all of the right of way obtained, except five miles, for an extension of this railway between Timpson and Carthage, Tex. Most of the necessary capital has been secured, and the contract for construction has been awarded to Garrison, Avery & Co., of Timpson. Seven miles of the line are now in operation, seven miles graded for ties and bridges and the remaining six miles are to be graded within 60 days. John Burkett, Ch. Engr., Kokomo, Ind.

TOLUCA & TENANGO.—E. W. Knapp, Master Mechanic, Box 59, Toluca, Mexico, informs us that the engineers are now in the field locating another extension of 15 kilometers (9.31 miles), from Tenango to Tejaloya, Mexico. The company will do its own work.

UNION, COVE & VALLEY.—This company was incorporated in Oregon June 24, with a capital stock of $25,000, to construct a standard gage railway from the station of the Union, Cornucopia & Eastern Ry. in Union to Cove, Ore., a distance of about 12 miles. It is the intention of the company to begin surveying the route at once. The grading, tieing and ironing of the road will be under the direction of Joseph Johnson, Supt. of Construction. It is expected to have the work completed by October 15. The directors of the new company are, E. P. McDaniel, M. B. Rees, J. F. Phy, J. M. Carroll, P. J. Taylor, L. B. Rinehart and Joseph Johnson.

WISCONSIN.—J. S. Cowan, Almond, Wis., informs us that contracts will probably be let for the construction of this line in the latter part of July. The proposed route is from Plover, on the Green Bay & Western Ry., to Almond, via Keene and Lone Pine, Wis., a distance of 16 miles. No surveys have yet been made, nor has the right of way been obtained nor the capital secured. W. F. Hopkins, Ch. Engr., Green Bay, Wis.

WYOMING & MISSOURI RIVER.—This company has been organized, according to reports, to construct a line to the Hay Creek coal fields at once. W. S. Heckert and Geo. S. Harris, Belle Fourche, S. D., are said to have received the contract for grading and ironing the road.

STREET AND ELECTRIC RAILWAYS.

WHITMAN, MASS.—The selectmen, June 28, granted a franchise to the Whitman & Plymouth Electric Ry. Co. to build a line from this place to the East Bridgewater town line.

BATH-ON-HUDSON, N. Y.—It is reported that the Albany Ry. Co. will extend its tracks into this place.

ONEIDA, N. Y.—Geo. W. Chadwick, of Chadwicks, N.Y., is reported to be interested in the construction of an electric railway from this city to Sylvan Beach, through Durhamville. Irving, Wicks & Co., New York, are attempting to obtain the franchise for this work now owned by J. W. Warner, Oneida.

SIDNEY, N. Y.—Robt. Cartwright, of this place, has bought the Sidney & Franklin Electric R. R., at receiver's sale, for $225, being subject to a judgment for $202 and a $3,000 mortgage, according to reports.

SOLVAY, N. Y.—The Syracuse, Skaneateles & Moravian R. R. Co. has petitioned the village trustees for a franchise for an electric railway through this place.

WALLOOMSAC, N. Y.—The Bennington & Hoosick Valley Electric Ry. was opened July 4, from North Bennington, Vt., to this place.

WHITEHALL, N. Y.—Chas. I. Baker, Troy, is said to be interested in an electric railway from this place to Granville.

DOYLESTOWN, PA.—Surveys for the Doylestown Ry. have been made and a franchise has been requested. The company also proposes to make extensions later to Morrisville, Centreville and Yardley. Pres., Frank N. Booz.

EASTON, PA.—The Easton, Palmer & Bethlehem Electric Ry. Co. has awarded the contract for the construction of its line to the Worcester Construction Co., Worcester, Mass., and work has already begun. The power house and car barns will be erected at Butztown, according to report.

ERIE, PA.—The Erie Electric Motor Co. is planning to build an extension to its electric railway in this city to a point near the end of the public dock at the foot of State St.

FOREST CITY, PA.—The Carbondale Traction Co. has been granted a franchise to build its line in this place. The company is required to accept the franchise in 20 days and to have the road extended to South St. within six months.

NAZARETH, PA.—It is proposed to build an electric railway from Bethlehem to this place, at a cost of about $50,000.

SCHUYLKILL HAVEN, PA.—The town council has granted a franchise to the Schuylkill Haven & Orwigsburg St. Ry. Co. to construct an electric railway in this borough, to connect with the tracks of the Pottsville & Reading Electric Ry.

WEST CHESTER, PA.—A meeting of the stockholders of the Philadelphia & West Chester Traction Co. will be held Aug. 23 to authorize a mortgage indebtedness of $340,000, with which to construct an extension to this place along the West Chester Turnpike, 10 miles.

BALTIMORE, MD.—Baldwin & Pennington are the architects for the new car barn of the Consolidated Ry. Co. This company has purchased the uncompleted electric railway between Baltimore and Ellicott City from the Columbia & Maryland Electric Ry. Co. and after completing it will operate it in connection with its Edmondson Ave. line through to Ellicott City.

WASHINGTON, D. C.—Congress has passed a bill requiring the Brightwood Ry. Co. to remove its overhead wires on Kenyon St., from 7th to 14th, and authorizing it to equip the road with the underground electric system at an estimated cost of $150,000.——Contracts for the construction of the Washington, Westminster & Gettysburg Ry. are reported to have been awarded.

NEWPORT NEWS, VA.—It is reported that before the Newport News & Old Point Ry. & Electric Co. can operate its electric line in this city, it will be necessary for the city to build two bridges across the tracks of the Chesapeake & Ohio Ry. W. J. Payne, Richmond, is one of the chief promoters of the project.

WHEELING, W. VA.—Elias McConnaughy, Bridgeport, has been given the contract, according to reports, for the grading of the extension of the Wheeling St. Ry. to the fair grounds.

FERNANDINA, FLA.—J. E. Starke, of Jacksonville, and others, have applied to the city council, according to report, for a franchise to build a street railway in this city.

BOWLING GREEN, KY.—The Bowling Green St. Ry. Co. has been reorganized by the Fidelity Trust Co. which had a lien of $23,000 upon it when it went into the hands of a receiver several months ago. The property of the railway company is to be sold. T. H. Whayne, Pres., may be addressed.

BIRMINGHAM, ALA.—The Birmingham Ry. & Electric Co. and the Birmingham Traction Co. are said to have reached an agreement by which cars will soon be running on First Ave., which will be relaid with heavier rails.

VICKSBURG, MISS.—The contract for the construction and equipment of the Vicksburg R. R., Power, Light & Mfg. Co. is reported to have been let. The line will probably be in partial operation early in September. Secy., M. J. Mulvihill, of Vicksburg.

BATON ROUGE, LA.—Fire destroyed car barn and six cars of the Baton Rouge St. Car Co. July 24, resulting in a loss of $20,000; almost covered by the insurance. Traffic will be suspended for several months.

XENIA, O.—J. M. Wilson, the promoter of the Dayton, Spring Valley & Wilmington Traction Co., is endeavoring to obtain a franchise to operate a line on Detroit St.

EAST ST. LOUIS, ILL.—The St. Louis & Belleville Electric Ry., of this city, has increased its capital from $50,000 to $500,000, according to report. John Day, Pres.

MILWAUKEE, WIS.—The Murray Hill Land Co. has secured an injunction restraining the Milwaukee Light, Heat & Traction Co. from changing the grade on Wells St.——The Waukesha extension of the Milwaukee Ry. & Light Co. was opened June 25. John I. Beggs, Mgr.

OSHKOSH, WIS.—A. B. Ideson, Vice-Pres., writes us that the Oshkosh, Omro & Berlin Electrical Ry. Construction Co. has been organized to build an electric railway from this city to Berlin, 26 miles, passing through three or four villages. The company will endeavor to secure a private right of way, 15 ft. wide, adjoining the highway and will be ready to finance within 90 days. The officers are: S. W. Hollister, Pres.; A. B. Ideson, Vice-Pres.; W. J. Wagstaff, Secy.; J. Howard Jenkins, Treas., and J. K. Tillottson, Mgr.

MINNEAPOLIS, MINN.—F. W. Cappelen, City Engr., writes us that the Twin City Rapid Transit Co. is pushing work on its line and expects to have it completed and in operation in a short time from this city to St. Paul, by way of Como Park.

KANSAS CITY, MO.—The Metropolitan St. Ry. Co. has decided to operate its Ninth St. cable line from Grand Ave. to the western terminus by electricity, according to report. The company is welding the joints in the rails on East 12th St. and on 15th St., from Highland Ave.; much welding still remains to be done.——The Brooklyn Ave. St. Ry. Co. contemplates building a line on Grand Ave., from 13th St. to 3d St., according to report.——The Kansas City Electrical St. Ry. Co. has been organized to build a line from 11th St. and Grand Ave. to a point near Westport.

WICHITA, KAN.—It is reported that the Commercial Club, of this city, has appointed a committee to confer with the city council in regard to constructing a street railway, the franchise for which has been asked for by an eastern promoter. C. G. Cohn, J. O. Davidson, C. Aylesburg, C. H. Brooks, E. Vail and J. H. Black are the committee.——The franchise granted to W. Q. Church and associates to build a street railway has been annulled by the city council, according to report, owing to the time condition having elapsed.

DEVIL'S LAKE, N. DAK.—Allan Tompkins is reported to be interested in building an electric road to Chautauqua, S. Dak.

PINE BLUFF, ARK.—A site, 180 × 200 ft., has been secured for the power house of the projected electric railway in this city, and work has been commenced.

DENVER, COLO.—The board of aldermen has voted to give a franchise to the Denver City Ry. Co. allowing it to change its motive power from cable to electricity and to extend its line on certain streets. The supervisors have not yet confirmed the vote.——The residents of Montclair, a suburb of this city, have petitioned the city council to grant a 20-year franchise to the Colfax Electric Ry. Co. to permit it to extend its line to their locality.

AUSTIN, TEX.—E. A. Ellis and others are reported to be interested in building a street railway in this city.

OAKLAND, CAL.—The Oakland Transit Co. has applied for a franchise on 12th St. and Oak St., according to report.

PASADENA, CAL.—The council granted a hearing recently to the Terminal Ry. Co. on its application for a franchise to operate an electric railway in this city. T. E. Gibbon, Att'y.

SAN MATEO, CAL.—The San Mateo Electric Ry. is reconstructing its 30th St. branch from Ocean View to Holy Cross Cemetery and is double-tracking its 18th St. line, from Guerrero to Danvers, according to report.

HAMILTON, ONT.—The city is contemplating purchasing and operating the Hamilton St. Ry. and will submit the question to the vote of the rate-payers on July 27.

ELECTRIC LIGHT AND POWER.

HOLYOKE, MASS.—J. J. Kirkpatrick, Cy. Engr., writes us that the committee appointed by the supreme court some time ago to appraise the value of the electric light plant, which it was voted to purchase, has not yet met. The plant has capacity for 250 1,200-c. p. arc lights.

SOMERVILLE, MASS.—Albion A. Perry, Mayor, writes us that at present no action is being taken by this city to secure or establish an electric light plant.

BELFORT, N. Y.—It is stated that Lafayette Wetmore, Martinsburg, N. Y., has purchased the grist mill site and water power at Belfort, 14 miles from Lowville. Mr. Wetmore proposes to build a plant at once to furnish 2,000 HP.

BUFFALO, N. Y.—J. G. White & Co., Baltimore, Md., have been awarded the contract for constructing a subway system in this city for the Buffalo General Electrical Works.

DOLGEVILLE, N. Y.—Jas. D. Feeter, of Little Falls, N. Y., is reported to have been appointed receiver for the Dolgeville Electric Light & Power Co.

ELMIRA, N. Y.—Geo. L. Gray, Alderman, writes us that the council has accepted a bid of the Elmira Illuminating Co. to light the streets for five years with 1,200-c. p. arc lights, at $80 a light a year. By the closing of this contract the question of building a municipal plant has been abandoned.

FULTONVILLE, N. Y.—H. W. Post, of the Cayadutta Generating Co., writes us that the company has about completed negotiations for water wheels, and will probably use the General Electric or Westinghouse generators, and will give the one or other the entire electrical contract for station and line equipment, etc. The plant will have a capacity for 50 2,000-c. p. arc and 1,000 16-c. p. incandescent lights.

HOMER, N. Y.—The Cortland & Homer Traction Co. has been granted a 5-year franchise for lighting this city.

MORRIS PLAINS, N. J.—Bids are asked by the board of managers until July 7 for furnishing and installing a plant, etc., at the New Jersey State Hospital at Morris Plains. Arch., Robt., C. Walsh, Morristown, N. J.

SEA ISLE CITY, N. J.—Bids are asked until July 7 for lighting the streets for 10 years with 80 32-c. p. incandescent lights. In addition to the city lighting there will be considerable commercial lighting. A. H. Sickles, Mayor, Sea Isle City, and 510 Minor St., Philadelphia.

LANCASTER, PA.—The Martic Water & Power Co. has leased the Columbia Dam from E. J. D. Cross for a term of 99 years for $75,000.

DURHAM, N. C.—The question of issuing $225,000 in bonds for the purchase of the plant of the Durham Electric Light Co. and water-works of the Durham Water Co., etc., will be voted upon Aug. 1.

FAYETTEVILLE, N. C.—The council is reported as considering the question of granting a franchise to a company for a plant and water-works.

LAFAYETTE, ALA.—It is stated that the council wants to purchase dynamos for 25 arc and 800 incandescent lights, etc. L. L. Torbert may be addressed.

PADUCAH, KY.—A consolidation of all the street car lines and electric light plants in this city has been made and a new company organized into which all the separate companies have been merged. The new bond issue and financial plan incidental to the reorganization was arranged by R. S. Vivian, Investment Broker, Portland Block, Chicago. The Paducah Ry. & Electric Light Co. was incorporated in June, with a capital stock of $200,000, by Geo. C. Thompson, T. J. Flournoy, Geo. C. Wallace and others.

COLUMBUS, O.—J. W. Jones, Supt. Deaf and Dumb Institute, writes us that an engineer has been appointed to prepare plans and specifications for the proposed plant. It will have a capacity for 12 arc and 1,200 incandescent lights; estimated cost, $7,000. The appropriation is made available after Feb. 15, 1899.

LEBANON, O.—Bids are asked until July 25 for the purchase of $20,000 of 5% electric lighting bonds, according to reports. R. B. Corwin, Village Clk.

PAINESVILLE, O.—Bids are asked until July 9 for furnishing two 60-light 2,000-c. p. arc dynamos, according to reports. E. D. Hartwell, Village Clk.

WELLINGTON, O.—It is stated that the following contracts were let June 24 for furnishing and constructing the plant and water-works, to cost $30,000: Electrical equipment, the Fort Wayne Electrical Corporation, Fort Wayne, Ind.; steam equipment, the Arbuckle-Ryan Co., Toledo, O.; stand pipe construction, the Standard Bridge & Boiler Co., Bellaire, O.; pipe distribution and pumps, T. S. & H. M. Brooks, Jackson, Mich. Bonds at 4% have been sold by the village for this plant and water-works.

TERRE HAUTE, IND.—Andrew J. Crawford, Terre Haute, has purchased the plant of the Terre Haute Electric Light & Power Co. for $40,000.

BELLAIRE, MICH.—This place voted June 20 to build a plant.

DETROIT, MICH.—M. E. Rasemann, 38 Buhl Block, is preparing plans for an addition to the plant of the Edison Illuminating Co.; estimated cost, $28,000.

EATON RAPIDS, MICH.—Bids are asked until July 8 for furnishing the machinery, etc., and installing a plant. The city proposes to contract for 30 or more arc lights for street lighting, the contract to be made for five years. Bids are requested to be made for 1,200 and 2,000 c.-p. arc lights, to be operated every night in the year from dusk to midnight. Bids should also include a schedule for commercial and residence incandescent lighting, to be operated every night during the year and during the whole of each night. H. L. Boice, Recdr.

GRAND RAPIDS, MICH.—Press reports state as follows: Another victory was won by the city June 25 in the struggle for a municipal plant. When the contracts were awarded for the plant recently, one of the bidders obtained an injunction restraining the city from executing the contract, on the ground that his was the lowest bid. Judge Burlingame on June 25 dissolved the injunction as the city charter provides that the board may award the contracts to any responsible bidders and not necessarily to the lowest. This will probably end all the litigation and the plant will now be built.

YALE, MICH.—Bids are asked until July 26 for furnishing and constructing a plant, as stated in our advertising columns. E. F. Fead, Clk.

WEST SUPERIOR, WIS.—The American Steel Barge Co., it is reported, will soon begin the construction of a new stone and brick power house, etc., to cost about $50,000.

ADA, MINN.—It is reported that Dr. Stuart is considering the question of building a plant.

MINNEAPOLIS, MINN.—The Minneapolis General Electric Co. is making an extension to its underground conduit system of about a mile of conduit. It is using the McRoy Vitrified Clay Conduit and laying from 4 to 16 ducts.

RICEVILLE, IA.—The construction of a plant is proposed, according to reports.

WATERTOWN, S. DAK.—L. D. Lyons writes us that nothing has yet been done with regard to the proposed plant. The city is at present moving slowly with the question.

KANSAS CITY, MO.—C. S. Sweetland, of the electric light company, of Kansas City, Kan., and R. J. Ingraham have applied for a franchise to supply this city with cheaper electric lights. The power will be transmitted from the plant at Riverview, which plant it is proposed to enlarge.

MOUNT GROVE, MO.—We are informed that the Star Roller Mills will want a 100-light dynamo for its new plant at once.

BATESVILLE, ARK.—Bids are asked until July 14 for furnishing the machinery and for constructing the plant and water-works; estimated cost, $25,000. Engr., Owen Ford, Security Bldg., St. Louis, Mo.

BUTTE, MONT.—Press reports state that liens have been brought against the Montana Power Co. for $54,955. The company was organized some time ago by St. Paul parties to furnish power, light and water, to the mines, etc. It is probable that the works are not yet completed.

NEW WHATCOM, WASH.—It is reported that the electric plant and the mill of the Bellingham Bay Improvement Co. were destroyed by fire June 28, causing a loss of about $400,000. The electric light plant is said to have had a capacity for 200 arc lights. Mgr., C. L. Anderson.

OAKLAND, CAL.—T. C. Bullock, of the St. and Electric Co., has applied for a 50-year franchise for transmitting electric power from the Blue Lakes, Amador county, to this city.

WALLACE, IDAHO.—The Wallace Mfg., Electric & Water Co., it is reported, has completed plans for a new power station to be 36 × 73 ft. A 150-HP. engine will be put in. The station, it is expected, will be completed by Sept. 1.

SANTIAGO DE CHILI, CHILI.—It is reported that a company has been formed at Berlin, Germany, under the name of the Electric Power Co. of Santiago de Chili, with a capital stock of 24,000,000 marks, of which Wernher, Beit & Co., of Berlin, take as much as 12,000,000 marks, while the balance is taken in equal proportion by the Societe Generale d'Electricite. Part of the capital will be offered for subscription in England. Extensive electrical undertakings in Chili are soon to be started by the company.

NEW COMPANIES.—Standard Electric Vapor Motor Co., New York; $50,000; S. W. Warner, E. L. Warner, W. M. Warner, Yonkers.

Lima-Honoeye Electric Light Co., Honoeye Falls, N. Y.; $125,000; H. H. Sitoll, R. L. Fryer, J. C. Conway, P. P. Miller, H. W. Box, A. L. Williams, A. M Holdin, H. C. Gilbert, Clarence McGregor, Buffalo.

Salem Electric Co., 93 Market St., Salem, N. J.; $50,000, with $15,050 paid in; John M. Carpenter, Wyatt W. Miller, Jr., Robt. Gwynne, Henry Kirk.

Port Chester Electric Lighting Co., Port Chester, N. Y.; $50,000; to operate in the towns of Westchester county; William L. Ward, Addison Johnson, Port Chester; William E. Ward, Rye, N. Y.

United States Light, Water & Power Co., 222 Washington St., Jersey City, N. J.; $125,000; F. W. Kalbfleisch, W. Curry, Brooklyn; George Weldon, Summit Ave., Jersey City. The company will purchase water-works, operate them and build electric light and power plants.

Illinois Power Co., Louisville, Ky.; $50,000; Robert E. Woods, H. S. Brashear, C. C. Boswell, D. E. Coulter, Louisville; R. A. Brashear, Gas City, Ind.

Cayadutta Electric Generating Co., Fultonville, N. Y.; to build a power plant and dam on Cayadutta Creek, near Sammonsville; a plant for furnishing 800 incandescent and 50 arc lights; A. Z. Wemple, Dr. H. W. Post, Fultonville; J. S. Wilson, Fonda, N. Y.

Ephrata Electric Co., Ephrata, Pa.; $15,000; F. E. Bailey, Philadelphia; A. W. Mentzer, Treas.; H. G. Mentzer, Ephrata; S. N. Bailey, Dillsburg, Pa.

North Jersey Light & Power Co., Montclair, N. J.; $15,000, with $1,050 paid in; Wm. T. Francisco, Albert C. Williams, Harry M. Warren, Montclair.

Beacon Light Co., three companies to operate in Ridley Park, Darby and Glenolden, Pa.; $1,000, with $100 paid in; J. Engle Cochran, Jr., Treas., 704 E. 14th St., Chester, Pa.; Geo. C. Hetzel, Ridley Park, Pa.; Ernest H. Davis, Brooklyn, N. Y.

Albion Power Co., Albion, N. Y.; $50,000; Raymond B. Johnson, Buffalo; S. T. Church, Albert Culver, Albion; W. C. Johnson, F. A. Dudley, Niagara Falls, N. Y.

Rocky Mountain Power Co., Denver, Colo.; $500,000; to operate in Arapahoe, Boulder, Jefferson, Clear Creek and Gilpin; Mina S. Page, J. G. O'Bryan, C. E. Rich, R. C. Bogy, A. C. Foster.

BRIDGES.

RUMFORD, ME.—Bids are asked until July 20 for constructing a steel truss bridge, 198 ft. long and 20 ft. wide, over the Androscoggin River, at Rumford Falls, to cost about $16,000. Chas. A. Mixer, Engr., Rumford Falls; J. H. Martin, First Selectman.

NEW CASTLE, N. H.—Plans have been completed by Dudley & Doherty, Engrs., Manchester, for the construction of three bridges, on the proposed Ocean Boulevard, over Rye Harbor and Hampton River.

BUFFALO, N. Y.—The board of public works will soon ask bids for the construction of a bridge over the Buffalo River at Seneca St. Frank W. Goethoefer, Cy. Clk.

HYDE PARK, N. Y.—D. Cuozzo, 150 Nassau St., New York, has commenced work on the new masonry arch bridge of 70-ft. span across Crum Elbow Creek on the New York & Albany Post Road, and retaining walls for the road embankments, for F. W. Vanderbilt and the town of Hyde Park, jointly; estimated cost, about $13,000, of which Mr. Vanderbilt shares three-fourths. Owen Morris, Engr. Hyde Park.

CAMDEN, N. J.—The following bids were received June 29 for constructing a steel bridge over Cooper's Creek at State St., as advertised in Engineering News. J. J. Albertson, County Engr.: Owego Bridge Co., Owego, N. Y., $23,000; Groton Bridge & Mfg. Co., Groton, N. Y., $[illegible] B. F. Sweeten & Son, Camden, N. J. (accepted), $22,776.

TUCKAHOE N. J.—J. C. R. Smith, Clk. Com. Bd. Freeholders, Ocean View, informs us that the following bids were received June 28 for a steel bridge 120 ft. long over the Tuckahoe River, as advertised in Engineering News. F. R. Long, Engr., 320 Broadway, New York:

Wrought Iron Bridge Co., Canton, O.	$4,213
New Jersey Steel & Iron Co., Trenton, N. J.	4,675
New Columbus Bridge Co., Columbus, O.	4,300
King Bridge Co., Cleveland, O.	5,750
Horseheads Bridge Co., Horseheads, N. Y.	4,248
Nelson & Buchanan, Chambersburg, Pa. (accepted).	3,990
Canton Bridge Co., Canton, O.	4,175
Berlin Iron Bridge Co., East Berlin, Conn.	4,590
F. R. Long & Co., New York	5,100
Toledo Bridge Co., Toledo, O.	5,750
Bracket Bridge Co., Cincinnati, O.	3,998
Youngstown Bridge Co., Youngstown, O.	5,350
Groton Bridge & Mfg. Co., Groton, N. Y.	4,430
Champion Bridge Co., Wilmington, O.	4,375
Owego Bridge Co., Owego, N. Y.	5,150

TOWSON, MD.—Bids are asked until July 13 for constructing an iron bridge 116 ft. long and 16 ft. wide, on stone foundation. B. H. Mays, Engr., Philopolis; C. H. Callings, Ch. Clk. County Comrs, Baltimore.

NEWPORT NEWS, VA.—The council has passed an ordinance authorizing the issue of $40,000 in bonds for the construction of three bridges over the Chesapeake & Ohio Ry.

SPRINGFIELD, TENN.—Bids will soon be asked for the construction of an arch bridge across Black Branch. Address Mayor Bell or Alderman McMurray.

CINCINNATI, O.—Bids are asked until July 30 for constructing an iron truss bridge and substructure, in Colerain township. Eugene L. Lewis, County Audr.

DAYTON, O.—Bids are asked until July 12 for constructing a bridge over the Great Miami River, according to reports. A. G. Feight, County Audr.

LISBON, O.—C. H. Smith, Gen. Mgr., Pittsburg, Lisbon & Western Ry. Co., Lisbon, informs us that it is proposed to construct two new bridges, of stone and steel; estimated cost, $4,500.

NEW PHILADELPHIA, O.—New bids will be asked by the county commissioners for the construction of an iron bridge over the river at Blicktown, to cost about $8,000.

YOUNGSTOWN, O.—Bids are asked until July 8 for the purchase of $90,000 of 4½% bridge bonds. C. F. Brenner, County Audr.

DETROIT, MICH.—The Detroit & Lima Northern Ry. Co. will apply to the county supervisors on July 29 for permission to construct a 102-ft. draw-span plate girder bridge over the Ecorse River, to replace the present structure. J. R. Megrue, Vice-Pres. and Gen. Mgr., Detroit.

DETROIT, MICH.—Commissioner Kallman, Bd. Pub. Wks., has written Mayor Maybury to urge the construction of a wider bridge from Owen Park to Belle Isle; $30,000 was left over from last year's appropriation.

MUSKEGON, MICH.—Bids are asked until July 18 for building a bridge over Muskegon Lake and for the substructure of three iron bridges, as described in our advertising columns. J. Bierma, Chn. County Comrs.

IVESDALE, ILL.—Bids are asked until July 7 for constructing an iron bridge 40 × 14 ft. Ira O. Baker, Engr., Champaign, Ill.

SIOUX CITY, IA.—J. M. Lewis, Acting Cy. Engr., informs us that a contract has been awarded to C. E. H. Campbell, Council Bluffs, for constructing a 100-ft. span steel bridge over Floyd River, on Charles St.

FARGO, N. DAK.—Bids are asked until July 8 for constructing eight pile bridges, from 30 to 50 ft. long. O. J. Olson, County Audr.

TOPEKA, KAN.—S. S. McFadden, Cy. Clk., informs us estimates have been submitted for the construction of a pile bridge at Lake St., to cost about $1,251. Bids have not yet been asked.

WICHITA, KAN.—Bids are asked by the county clerk until Aug. 1 for constructing three iron bridges; estimated cost, $650, $850 and $900 each. R. H. Brown, Des. Engr., Wichita.

STOCKTON, MO.—Bids are asked until Aug. 1 for the construction of a steel bridge about 112 ft. long, on stone foundation. Address H. W. Englman, Bear Creek, Mo.

CHEHALIS, WASH.—The county commissioners have decided to construct two bridges across the Chehalis River this summer, one at Claquato, to cost about $3,500, and at Centralia, to cost about $10,000.

WEISER, IDAHO.—Bids are asked until July 9 for repairing the Middle Fork wagon bridge, consisting of 112 ft. of trestle approach. I. F. Smith, County Clk.

BROOKE, ONT.—Bids are asked until July 11 for constructing two bridges, according to reports. Address L. Lindsay.

BUILDINGS

BATH, ME.—A fire in this city July 4 destroyed a number of buildings, causing a reported loss of $100,000.

BARRE, VT.—All bids for erecting a new city hall building have been rejected owing to the high figures. It is likely that the granite part of the present plans will have to be omitted or an extra $10,000 added to the original appropriation.

PITTSFIELD, MASS.—The contract for rebuilding the American House is stated to have been awarded to Dodge & Devanney, of this city, at a cost of about $60,000.

SPRINGFIELD, MASS.—Bids are asked until July 11 for the erection and plumbing of new outbuildings for the Elm St. school. Arch., F. R. Richmond; also until July 13 for the erection of the Brightwood school building. Arch., B. Hammett Seabury, Gill's Block. C. E. Brown, Chn. Cy. Property Com.

NEWPORT, R. I.—The following bids were received June 28 for the erection of a naval hospital for contagious diseases at the U. S. naval station at Newport: Wm. F. Wilber & Frank E. Manchester, $9,834; James M. Gillies, $9,842 (informal). As all bids were in excess of the appropriation no award will be made.

BROOKLYN, N. Y.—George Mertz & Son, of Port Chester, N. Y., are said to have received the general contract for the $30,000 residence, 72 × 98, to be erected at 99th St. and Shore Road for Kate M. Johnson, 268 23d St. Archs., Little & O'Connor, 18 West 34th St., New York. ——Henry J. Brown & Son, 1534 Fulton St., have been awarded the mason, carpenter and iron contract, and James Keenan, Fulton St., near Grand Ave., has the plumbing contract for the alterations to the building at Throop Ave. and Hancock St. for Theodore Kruger. Archs., Dodge & Morrison, 41 Wall St., New York.

LITTLE FALLS, N. Y.—Contractor Dove, of Little Falls, is said to have been awarded the contract for the construction of the new high school building, exclusive of heating, plumbing and ventilating, at $55,589.

NEW YORK, N. Y.—Plans have been filed by Smith & Raffler, 130 East 86th St., for a 5-story brick flat and store building at 107th St. and Manhattan Ave., to cost $140,000. Archs., Neville & Bagge, 217 West 125th St.; by Eaton & Mains, for the Methodist Book Concern, for an 8-story brick business building at 4 West 20th St., to cost $50,000. Archs., E. H. Kendall; by P. J. Herter, 1032 Lexington Ave., for two 5-story brick flat and store buildings at 433 and 435 West 24th St., to cost $50,000. Archs., P. Herter & Son; by Rachel Weinstein, for two 6-story brick flat and store buildings at 50 and 52 Lewis St., to cost $50,000; Archs., Horenburger & Straub, 122 Bowery, by Julius and Gus J. Fleischman, 19 West 124th St., for four 5-story brick flat buildings at 5th Ave. and 118th St., to cost $70,000, and for three 5-story flat buildings on 118th St., near 5th Ave. Arch., Geo. F. Pelham, 503 5th Ave.; by Bernard Havanagh, 469 West 147th St., for six 4-story brick flat buildings on Brook Ave., near 169th St., to cost $60,000. Arch., John P. Walther, 205 East 125th St.

SCHENECTADY, N. Y.—The Van Dorn Iron Works, of Cleveland, O., has received the contract for erecting the new county jail building, and John McEncroe, of Schenectady, will build the mason work. Contracts have not yet been awarded for heating and ventilating.

SONYEA, N. Y.—Bids are asked by the managers of the Craig Colony for Epileptics until July 19 for the construction of 15 dormitory buildings and a superintendent's residence. Archs., Carrere & Hastings, 28 East 41st St., New York.

SYRACUSE, N. Y.—Plans and specifications are asked by the supervisors of Onondaga county until August 1 for improvements and additions to the county penitentiary and jail buildings. Address Ray B. Smith, 618 Kirk Block, Syracuse.

TROY, N. Y.—Bids are asked until July 19 for the erection of a new public school building in this city. E. Ogden Ross, Secy. Contracting Board.——Plans have been prepared for a new 5-story brick addition to the Windsor Hotel, for J. T. Quackenbush, to cost about $18,000. Arch., E. W. Loth, 253 Broadway.——An addition will be erected to the Troy "Times" Building, at 3d St. and Broadway, to cost about $35,000. Arch., M. F. Cummings & Son, Times Bldg.

NEW BRUNSWICK, N. J.—Plans have been accepted for a 2-story brick and stone 12-room school building, 73 × 124 ft., to be erected on French St. We are informed that bids will soon be asked. Otto Stillman, Chn. Bldg. Com.; Geo. K. Parsall, Arch., 86 Church St.

ALLEGHENY, PA.—The Third Ward school board has awarded the contract for erecting new school buildings at North Ave. and James St. to S. H. McCain, of Allegheny, at $109,690. Work will begin about July 1.

BESSEMER, ALA.—The Bessemer Land & Improvement Co. is reported as making surveys for increasing the water supply of the town.

CROWLEY, LA.—J. E. Barry, Mayor, writes us that the Consolidated Engineering Co., Ltd., New Orleans, La., has been awarded the contract for building the works and light plant for this place.

CINCINNATI, O.—Bids are asked until July 29 for constructing seven sluice gates for the intake for the Eastern pumping station, as described in our advertising columns. Chas. G. Roth, Clk. Bd. Water Comrs.

ELYRIA, O.—W. H. Park writes us that this place voted June 27 to purchase the works of the Elyria Gas & Water Co. for $45,000. The city was to take possession of the property July 1. Supt., G. E. Crisp.

GLOUSTER, O.—This place voted June 23 to build works, according to reports.

NORWALK, O.—The following contracts are reported to have been let June 29 for furnishing and constructing the stand-pipe, pumping station, etc., as advertised in Engineering News: B. P. Foster, Norwalk, stand-pipe, $2,300; Standard Boiler & Bridge Co., Alliance, metal work for stand-pipe, $6,588: the Snyder-Hughes Co., Cleveland, pumping engine, $7,830: S. Tolliat, Alliance, O., pumping station, building and chimney, $6,471; Erie City Iron Works, Erie, Pa., boiler, $1,085.

DELPHI, IND.—Bids are asked until July 19 for furnishing the materials and for constructing a 250,000-gallon masonry lined reservoir for the water-works. Wm. C. Smith, Cy. Attorney.

WHITING, IND.—Bids are asked until July 18 for furnishing and laying 6 to 10-in. cast-iron water pipe, hydrants, valves, etc. J. G. Erdlitz, Town Clk.

CASS CITY, MICH.—Bids are asked until July 20 for the purchase of $18,000 of 4% water and light bonds. H. W. Seed, Clk.

YALE, MICH.—Bids are asked until July 19 for furnishing and constructing works, as described in our advertising columns. E. F. Fead, Clk.

DUQUOIN, ILL.—Bids were asked until July 5 for furnishing the material and for building a dam, gate house, pumping station, pumps, etc., for completing the works, the contracts for a part of which were let last year. Job Cook, Cy. Clk.; D. W. Dunn, Mayor.

BLAIR, WIS.—E. L. Immell, Village Pres., writes us that the proposed works will have a reservoir on a hill 200 ft. high, three-quarters of a mile of 8-in. mains, etc.; estimated cost, $4,000; population, 500. E. O. Gellfellan is on the committee.

MENASHA, WIS.—Henry M. Northrup, Menasha, is reported to have applied for a franchise, the supply to be secured from wells. Population, 8,000. W. W. Reed, Cy. Engr.

ALDEN, IA.—M. Pritchard, Mayor, writes us that the city is ready to receive bids for furnishing and constructing works to cost $5,000. The works will have a 50-ft. steel tower, a 20 × 20-ft. wooden tank, 4 and 6-in. pipe, etc. The pump will not be determined upon until the well is completed. Engrs., Jackson & Moss, Des Moines, Ia.

MINDEN, IA.—Jno. W. Crow, Mayor, writes us that the following bids were received June 30 for furnishing the material, etc., and for building works:

	Per specifications.	Amended bids.
Casselbery & Schriner, Des Moines	$5,800	....
U. S. Supply Co., Omaha, Neb.	4,668	$4,293
Connelly & Shaw, Omaha, Neb.	4,750	4,002

The contract was awarded to Connelly & Shaw at $4,002. The council after considering the bids asked the bidders to put in a bid for steel tower and Roots spiral pipe, which resulted as follows: Connelly & Shaw, deduct $623 from original bid on tower and $125 on Roots pipe; U. S. Supply Co., deduct $150 and $225, respectively.

SPARTA, MINN.—Bids are asked until July 22 for furnishing and constructing works to cost $6,000; bond, $4,000. Engrs, Patton & Frank, Duluth, Minn.; Recdr., Clyde Bender.

BATESVILLE, ARK.—Bids are asked until July 14 for furnishing the material and for constructing the proposed works and light plant; estimated cost, $25,000. Engr., Owen Ford, 710 Security Bldg., St. Louis, Mo.; Chn. Com., C. R. Handford.

SAN JOSE, CAL.—Bids are asked by the supervisors until July 18 for furnishing and constructing a steel water tower and tank, etc., for the infirmary.

TRENTON, ONT.—Bids were asked until June 30 for furnishing the machinery and for constructing works. J. D. Evans, Engr. Trenton Water Co.; A. W. Hawley, Pres.

IRRIGATION.

NEW COMPANIES.—Sun River Operative Ditch Co., Helena, Mont.; $10,000; to construct a ditch in Cascade county; G. M. Bourquin, A. S. Douglas, Benj. Borgstede.

Pleasant Valley Canal Co., Helena, Mont.; $5,500; to construct an irrigation ditch or canal, taking the water from Rock Creek; Jeff Dinsdale, William Tennet, E. E. Esselty, L. D. Miller, D. W. Long, Martin Johnson, John McCune, W. P. Meyer, J. C. Simpson, William McIntyre.

Beaumont Irrigating Co., Beaumont, Tex.; $75,000; W. S. Davidson, J. B. Goodhue, J. E. Broussard, A. L. Goodhue and I. K. Bordages.

SEWERAGE.

BRENTWOOD, N. H.—The sewage disposal plant and filter beds at the Rockingham county farm, Brentwood, N. H., are to be enlarged and improved in accordance with plans submitted by Dudley & Doherty, 936 Elm St., Manchester, N. H.

BOSTON, MASS.—Bids are asked until Sept. 3 for furnishing and constructing a sewage pumping station, as described in our advertising columns. Wm. M. Brown, Jr., Ch. Engr. and Supt. Metropolitan Sewerage Comrs., 1 Mount Vernon St.

HOLYOKE, MASS.—Chas. P. Ferry, of the Bd. Pub. Wks., writes us that it is probable that an appropriation for sewering the Highlands will be made soon. A local paper states that the whole system for the Highlands will cost about $75,000.

SPENCER, MASS.—This place has voted to extend the Cherry St. sewer. N. E. Craig, Supt. Sewers.

DERBY, CONN.—E. S. Gordy writes us that the whole question of a system rests in abeyance. It is hoped to accomplish something during the next 12 months.

AMSTERDAM, N. Y.—Bids are asked until July 21 for constructing sewers in four streets. Geo. McClumpha, Secy. Sewerage Comm.

TONAWANDA, N. Y.—The boards of public works of this city and North Tonawanda are reported as again considering the question of improving the systems of these places.

JERSEY CITY, N. J.—The street and sewer board has asked the finance committee for $60,000 to reconstruct certain sewers.

CAMBRIDGE SPRINGS, PA.—Ross & Robinson have been awarded the contract for constructing sewers in Main St. and Beach Ave.

ESPLEN, PA.—Bids are asked until July 7 for constructing a 24-in. pipe sewer with laterals in Third St. Engr., G. A. Gilfillan, 8 Fidelity Bldg., Pittsburg; Clk., A. W. Gibson, Esplen, P. O. McKee's Rocks, Pa.

PHILADELPHIA, PA.—Councils have appropriated $500,000 for building certain main sewers.

PHILADELPHIA, PA.—Bids will soon be asked by the director of the department of public works for constructing sewers in about 40 streets. Chas. F. Warwick, Mayor.

TAMAQUA, PA.—Samuel Beard, Town Clk., informs us that Ward & Stucker, Harrisburg, have been awarded the contract for building pipe sewers, as advertised in Engineering News. The bids were as follows:

Samuel W. Frescoln, Reading, Pa.	$4,949
E. H. Post, Wilkesbarre, Pa.	6.218
Phil. J. Boyle & Co., Hazleton, Pa.	6,099
Ward & Stucker, Harrisburg, Pa.	4,559
P. J. Cleary, Shenandoah, Pa.	6,8[illegible]0
W. J. Coons, Kingston, Pa.	5,140
Humphreys & Rowe, Ashland, Pa.	8,158
J. B. Urie, Tamaqua, Pa.	6,944
Hadesty & Kitchen	7,048

WARREN, PA.—Bids are asked until July 9 for building 2,900 ft. of pipe sewer in the 5th and 6th Wards. R. G. Mead, Chn. Com.

WASHINGTON, D. C.—Bids are asked by the district commissioners until July 16 for constructing sewers.——Congress has appropriated $25,000 for the purchase of land and for preparing plans for the proposed sewage pumping station, under the approved project for sewage disposal in the District of Columbia.

GOLDSBORO, N. C.—Bids are asked until July 21 for furnishing and constructing about 12 miles of 20 to 6-in. pipe sewers, as stated in our advertising columns. Engr., J. L. Ludlow, Winston, N. C.; Cy. Clk., D. J. Broadhurst.

SPARTANBURG, S. C.—J. M. Elford, Clk. and Treas., writes us that the contract for surveys, plans and specifications for a system has been let to J. L. Ludlow, Winston, N. C. Arrangements have also been made for awarding the contracts.

WAYCROSS, GA.—Press reports state as follows: The proposition of C. G. McCranie to build the system for Waycross for about $36,000 includes seven miles of additional sewers than was designated in Mayor Knight's estimate. It is presumed that Mr. McCranie's offer is bona fide, and in case the $50,000 bonds shall be voted he will stand a good chance of getting the contract. There is some little opposition to the bonds, but the only objection raised so far by the opposition is that $100,000 is preferable to $50,000, and that the time is not opportune.

MEMPHIS, TENN.—A. T. Bell, Cy. Engr., writes us that 17½ miles of sewers have been built this year. Nothing more will be done before the spring of 1899.

LEXINGTON, KY.—Local papers state that arrangements are being made for constructing a larger sewer at the Main St. railway crossing.

DETROIT, MICH.—Bids are asked until July 8 for furnishing such sewer pipe as may be required during the year ending June 30, 1899. D. W. H. Moreland, Pres. Bd. Pub. Wks.

MARSHALL, MICH.—Riggs & Sherman, 613 The Nasby, Toledo, O., have been engaged to prepare plans and specifications for the proposed system and certain paving.

TRENTON, MICH.—The council will probably soon issue $1,500 in bonds for building 2,500 ft. of 18-in. pipe sewer.

ST. PAUL, MINN.—Anderson & Johnson have been awarded the contract for constructing a sewer in Gauitier St. at $4,923.

HUDSON, WIS.—J. W. Bashford, Mayor, writes us that no sewers will be built this year.

DENVER, COLO.—Plans are reported as about completed for the proposed system of storm sewers for East Denver. L. N. Wood, Pres. Bd. Pub. Wks.

SAN LOUIS OBISPO, CAL.—The city engineer has submitted estimates for extending the system, at a cost of about $35,000.

CHARLOTTETOWN, P. E. I.—Bids are asked until July 8 for furnishing sewer pipe, etc., for the proposed system. Engr., F. C. Coffin, 53 State St., Boston, Mass.; Chn. Com., David Laird.

GUADALAJARA, JALISCO, MEX.—It is reported that the W. S. Dickey Clay Mfg. Co., Kansas City, Mo., has secured the contract to furnish this city with 300 carloads of sewer pipe for the proposed system for this city. The system will cost complete about $500,000.

GARBAGE DISPOSAL—STREET CLEANING

MANCHESTER, N. H.—It is reported by the local papers that the council will probably soon ask for bids for removing the garbage and refuse of the city. A citizen has applied for a franchise for the work, the city to pay him $18,000 a year.

CRANSTON, R. I.—Bids were asked until July 5 for collecting and removing the garbage from the villages of Auburn, Arlington, Cranston, Edgewood, Knightsville, Meshanticut and Pawtuxet during the ensuing year. Daniel D. Waterman, Council Clk.

ATLANTIC CITY, N. J.—The council has voted to issue $40,000 in bonds for building a crematory; the lot will cost, $6,000 and the plant $32,000. Councilmen Kelly and Lee may be addressed.

JERSEY CITY, N. J.—The street and water board has asked the council to appropriate $75,000 in addition to the usual appropriation for cleaning the streets.

MILWAUKEE, WIS.—Judge Ludwig has dissolved the temporary injunction restraining the city from selling $160,000 in bonds for the proposed garbage disposal plant, according to reports.

ST. LOUIS, MO.—Bids are asked by the board of health until July 8 for collecting and disposing of the garbage and refuse of the city for 10 years. The present contract with Edward Butler expires July 14.

STREETS AND ROADS.

DEERING, ME.—D. F. Griffin & Bros. submitted the lowest bids June 28 for laying 8,000 sq. yds. of granite paving, at $13,440.

NEW CASTLE, N. H.—The survey of the Ocean Boulevard has been completed and plans and estimates will be submitted at the next meeting of the council. Dudley & Doherty, Engrs., Manchester.

BURLINGTON, VT.—Bids are asked until July 10 for the purchase of $20,000 of 4% street improvement bonds. L. C. Grant, Cy. Treas.

REVERE, MASS.—Miric & Wentworth, Malden, have been awarded a contract at $9,600 for street work.

NEWPORT, R. I.—Bids are asked until July 15 for 6,630 sq. yds. of asphalt paving. William Hamilton, St. Comr.

BRIDGEPORT, CONN.—Main St. will be paved with asphalt at a cost of about $8,060. Thos. P. Taylor, Mayor.

HARTFORD, CONN.—Bids are asked until July 13 for constructing about 2,000 sq. yds. of Trinidad sheet asphalt and furnishing and laying concrete foundation. Chas. H. Northam, Pres.

NEW HAVEN, CONN.—Bids are asked until July 8 for paving Wall St. with concrete, from York St. to State St., and for furnishing crushed stone for the year. C. W. Kelly, Cy. Engr.

WATERTOWN, CONN.—Bids are asked until July 13 for improving a road from Watertown to Waterbury. Geo. A. Harper, First Selectman.

BINGHAMTON, N. Y.—Bids are asked until July 15 for brick paving in Court St., from Exchange to Carroll St. B. W. Mosher, Cy. Clk.

EAST AURORA, N. Y.—Bids are asked until July 11 for paving in Main St. C. H. Addington, Clk.

KINGSTON, N. Y.—J. T. Cummings, Cy Clk., has been ordered to advertise for bids for grading and curbing several streets.

NEW YORK, N. Y.—Bids are asked by the department of highways, 150 Nassau St., until July 14, for furnishing broken stone and screenings and 100,000 gallons of No. 6 paving cement; also for repairing asphalt pavement in certain streets in the Borough of Brooklyn. Jay A. Keating, Comr.

NORWICH, N. Y.—The board of trustees will vote on a resolution July 11 to pave East Main St., West Main St. and Broad St. with brick, to cost about $35,000. John W. Bingham, Clk. Bd.

POUGHKEEPSIE, N. Y.—The board of public works has awarded a contract to Cornelius Daley, at $14,602, for paving in Main St.

ROCHESTER, N. Y.—The following are the lowest bids received by the board of public works June 27 for paving: Warren-Scharf Asphalt Paving Co., asphalt, Columbia Ave., $41,431; asphalt, Tremont Place, $1,457; Chambers & Casey, macadam, Post St., $4,949.

TROY, N. Y.—Bids are asked until July 12 for paving Franklin St. with brick, from Congress St. to Ferry St. E. Ogden Ross, Secy. Contracting Bd.——Contracts were awarded June 28 to M. J. Jackson & Son, at $21,217, and Frank Besch, at $27,389, for brick paving in two streets.

FREEHOLD, N. J.—Bids are asked until July 13 for constructing 7,871 lin. ft. of gravel road, in Millstone township. J. D. Honce, Clk. Bd. Freeholders.

MORRISTOWN, N. J.—The board of freeholders have awarded a contract to Augustus Munson & Co., at $19,167, for grading and macadamizing the Basking Ridge Road.

NEWARK, N. J.—Bids are asked until July 7 for furnishing the materials and paving six streets with asphalt or granite. M. F. McLaughlin, Supt. Bd. St. Comrs.

CARBONDALE, PA.—Bids are asked until July 23 for about 7,460 sq. yds. of paving, as stated in our advertising columns. F. B. Clifford, Cy. Clk.

ERIE, PA.—Proposals will soon be asked for curbing several streets. T. Hanlon, Cy. Clk.

READING, PA.—Bids will soon be asked by the board of public works for brick paving in portions of nine streets, to cost about $100,000.

SUNBURY, PA.—Bids were received July 5 for about 5,350 sq. yds. of brick paving, 2,700 lin. ft. of curb, etc. P. H. Moore, Ch. Burgess.

TARENTUM, PA.—Bids are asked until July 20 for constructing 5,950 sq. yds. of pavement, according to reports. John Duster, Chn. Com.

DURHAM, N. C.—An election will be held on Aug. 1 to vote on the question of issuing $225,000 in bonds for street improvements, an electric light plant and water-works.

ASHLAND, O.—Bids are asked until July 30 for 1¼ miles of brick paving, as stated in our advertising columns. E. B. Westover, Clk.

COLUMBUS, O.—Bids are asked until July 12 for furnishing the material and constructing seven roads. W. H. Halliday, County Audr.

SOUTH BEND, IND.—Bids are asked until July 25 for constructing 26,000 sq. yds. of sheet asphalt pavement in West Washington St., from Michigan St. to South Walnut St. Wm. H. Rosencrans, Cy. Engr.

DETROIT, MICH.—The board of public works has awarded a contract to the Michigan Stone & Supply Co., at $16,993, to macadamize La Salle Ave.

DETROIT, MICH.—Bids are asked until July 11 for furnishing the material and constructing about 32,000 sq. yds. of cedar block paving on concrete. D. W. H. Moreland, Pres. Bd. Pub. Wks.

GRAND RAPIDS, MICH.—The Warren-Scharf Asphalt Paving Co. has been awarded a contract at $21,074 to pave Crescent Ave.

MARSHALL, MICH.—Riggs & Sherman, Engrs., 613 The Nasby, Toledo, O., are preparing plans and specifications for paving.

CHARLESTON, ILL.—Bids will be asked about July 27 for paving, according to reports. T. V. Miles, Cy. Clk.

CHAMPAIGN, ILL.—Bids are asked until July 14 for brick paving, as stated in our advertising columns. J. R. Scott, Pres. Bd. Local Improvements; R. P. Brower, Cy. Engr.

DECATUR, ILL.—It is proposed to pave portions of Jasper and Sangamon Sts. with asphalt; estimated cost, $19,899.

WAUKEGAN, ILL.—The board of local improvements has decided to pave and construct sidewalks in Water St., to cost about $6,900.

PORTAGE, WIS.—Bids are asked until July 8 for brick paving, according to reports. J. E. Jones, Mayor.

CEDAR FALLS, IA.—F. O. Jackson, Cy. Clk., informs us that bids will be asked after July 11 for brick paving in six blocks. D. M. Rosser, Engr., Cedar Falls.

DES MOINES, IA.—The council will vote July 11 on a resolution to pave two alleys with brick. John MacVicar, Mayor.

IOWA CITY, IA.—Bids are asked until July 15 for furnishing the material and constructing 3,090 sq. yds. of brick pavement, 1,727 lin. ft. of curb and 1,292 cu. yds. of grading. W. J. Bowen, Cy. Clk.; Arthur J. Cox, Cy. Engr.

SIOUX CITY, IA.—Bids are asked until July 12 for the following pavement: 6,258 sq. yds. of sheet asphalt, 24,572 sq. yds. of brick on concrete base and 12,313 sq. yds. of brick on sand foundation. J. M. Lewis, Acting Cy. Engr.

ANACONDA, MONT.—Bids are asked until Aug. 2 for laying out the Lincoln & Hehnville Road for a distance of 12 miles. H. B. Davis, County Surveyor; M. Martin, Clk.

HOUSTON, TEX.—An ordinance authorizing the city to borrow $100,000 for paving and sewer purposes has been referred to the ordinance committee.

SEATTLE, WASH.—Reports state that the question of constructing a road and bicycle path from Seattle to Tacoma is being considered. F. M. Little, Supt. Sts., may be addressed.

SPOKANE, WASH.—Bids are asked until July 14 for paving in Riverside Ave. with sheet asphalt on concrete foundation; also for maintaining the same for 10 yrs. B. H. Fowle, Secy. Bd. Pub. Wks.

ST. JOHN, N. B.—The board of public works has received estimates for the improvement of about 20 streets. Director Smith of Superintendent Martin may be addressed.

MANUFACTURING PLANTS.

BRIDGEPORT, CONN.—The factory of the Coach Lace Co., on John St., has been damaged by fire. The building is a 4-story brick structure, 150 × 50 ft., and the loss is estimated at $75,000.

BUFFALO, N. Y.—We are informed that Henry S. Schaefer's Sons, Oak and Virginia Sts., Buffalo, have received the contract for the erection of a new 8-story fireproof building, 182 × 150 ft., for the Larkin Soap Co.; estimated cost, $200,000. Arch., Robt. J. Reidpath, Real Estate Exchange, Buffalo.

BRONXVILLE, N. Y.—The factory of the Ward-Leonard Electric Co., in this village, was burned, July 2, causing a reported loss of $45,000.

ORANGE, N. J.—The hat factory of Austin Drew & Co., on Nassau St., was destroyed by fire July 4, causing a loss of about $80,000.

CONNELLSVILLE, PA.—It is reported that the Slaymaker-Barry Co. has decided to rebuild at once the lock works at South Connellsville, at a cost of about $40,000. Pres., S. R. Slaymaker.

YORK, PA.—The York Mfg. Co. will erect a 2-story machine shop at this place, according to reports. Electrical equipment will be required.

LOUISVILLE, KY.—Press reports state that the iron foundry of Snead & Co., which was destroyed by fire on June 23, will be rebuilt at once. Estimated loss, $150,000; insurance, $136,800. Vice-Pres., Udolpho Snead.

SIOUX CITY, IA.—Bids are still being received, according to reports, on the equipment for the new brewing plant which will be built in this city for the Sioux City Brewing Co., at an estimated cost of $250,000 for the buildings and $100,000 for the equipment. We are informed that there will be installed therein several Corliss engines, tubular boilers, an electric light plant capable of supplying 150 lights, etc. Arch., Wilhelm Greisser Engineering Co., 909 Schiller Bldg., Chicago, Ill.

KANSAS CITY, MO.—M. G. Orendorff, Secy. and Treas., Parlin & Orendorff Co., of Canton, Ill., informs us that the company will erect a 6-story building, 192 × 127 ft., in this city, for use as an agricultural implement and jobbing warehouse. Plans have not yet been decided upon, and no contracts have been awarded. Plans will probably be received on architect's specifications some time this month. Electric lights will be used; no engines other than electric dynamos for operating elevators will be required. Estimated cost of full equipment, $75,000.

MOUNT GROVE, MO.—The Star Roller Mills, of Mount Grove, informs us that the capacity of the flour mills will be increased to 200 barrels. No engines or boilers are required, but a dynamo to supply 100 electric lights will be bought. No contracts have been let.

FAIRHAVEN, WASH.—Reports state that H. L. & J. W. Roan will erect an ice and cold storage plant at this place at a cost of about $25,000.

GAS PLANTS.

FRANKLIN, N. Y.—A. J. Richardson will lay gas mains to supply the city with natural gas.

CAMDEN, N. J.—Bids are asked until July 20 for supplying this city with gas light during the ensuing year. Chas C. Southard, Chn. Lighting Com.

DELAWARE, O.—J. C. Childs, owner of the natural gas fields at Mount Vernon, is reported to have been granted a franchise to supply this city with gas.

NEW COMPANIES.—Henry G. Thompson Co., New Haven, Conn.; $50,000; to manufacture gas meters and other machinery; Henry G. Thompson, Samuel G. Mower, H. Grant Thompson, New Haven.

Uniontown Cotton Oil Co., Uniontown, Ala.; $40,000; J. H. White, W. H. Taylor, G. B. Johnstone, W. J. White.

American Illuminating Gas & Fuel Co., Boston, Mass.; $1,000,000, with $125 paid in; E. D. Luxton, New York; H. W. Bates, J. D. Huhn, Boston.

MISCELLANEOUS CONTRACTS.

FIRE ENGINES.—Lincoln, Neb.—The council has decided to purchase a fire engine.

FIRE APPARATUS.—Montgomery, Ala.—The mayor has been authorized to purchase new fire apparatus.

TELEPHONE LINE.—Hanover, Pa.—The Hanover Telephone Co. has decided to extend its line to Glenville.

TELEPHONE SYSTEM.—Windsor, Mich.—The council has granted a 20-year franchise to the People's Telephone Co.

FIRE ALARM SYSTEM.—Peoria, Ill.—The fire and water committee is investigating the cost of installing a fire alarm system.

FIRE ENGINE.—Cleveland, O.—Bids are asked until July 14 for furnishing one first size steam fire engine. G. L. Hechler, Dir. Fire Service.

BONDS.—Holly Springs, Miss.—Bids are asked until Aug. 2 for the purchase of $43,000 of 6% bonds. John Calhoon, Mayor; G. C. Cannon, Clk.

RETORTS.—Hamilton, O.—Bids are asked until July 15 for constructing three benches of retorts with new iron work for the same. M. O. Burns, Cy. Clk.

RECREATION PIER.—Brooklyn, N. Y.—The dock department will soon call for bids for completing the Brooklyn recreation pier; estimated cost, $8.000.

DREDGING.—Waukegan, Ill.—Bids are asked until July 9 for dredging the channel of the harbor of this city, making the same 18½ ft. below datum. H. Thacker, Cy. Clk.

DIKE.—York River, Va.—Bids are asked until Aug 6 for constructing a dike at York River, as stated in our advertising columns. Lt.-Col. Chas. J. Allen, U. S. Engr., Washington, D. C.

WHARF AND FREIGHT SHED.—Halifax, N. S.—Bids are asked by the Intercolonial Railway Co. until July 15 for constructing a wharf and freight shed at this place, according to reports. D. Pottinger, Gen. Mgr., Moncton, N. B.

DREDGING, ETC.—Virginia.—Bids are asked until Aug. 6 for dredging and rock excavation in Rappahannock River and Urbanna Creek, Va., as stated in our advertising columns. Lt.-Col. Chas. J. Allen, U. S. Engr., Washington, D. C.

CHANGING CHANNEL.—Dayton, O.—The contract for changing the channel of the Miami River from the north corporation line to the Dayton & Michigan R. R., was awarded, June 30, to John Williams & Co., at $38,079, according to reports.

PIER AND DREDGING.—Cleveland, O.—L. P. & J. A. Smith Co., Cleveland, has submitted the lowest bid, at $451,264, for constructing and removing a part of the west pier, dredging and completing the east breakwater. Col. J. A. Smith, U. S. Engr.

UNDERGROUND CROSSING.—Kingston, N. Y.—Bids are asked until July 16 for furnishing the material and for constructing an underground crossing for the Colonial City Traction Co., as stated in our advertising columns. (Postponement from July 9.) C. Gordon Reel, Supt. and Engr.

MONITORS AND TORPEDO-BOATS.—Washington, D. C.—Bids are asked by the navy department until Aug. 9 for furnishing and constructing torpedo-boats and destroyers and until Oct. 1 for four monitors about 225 ft. long and 50 ft. wide, to cost about $1,200,000 each, exclusive of armament.

DRAIN.—Coldwater, Mich.—Bids are asked until July 15 for the construction of Kinderhook No. 1 drain, including a catchbasin. Work will be let in five contracts, as follows: Furnishing tile drain, constructing tile drain, constructing open drain, cleaning old drain and constructing catch basin. Danl. E. Weage, County Drain Comr., Coldwater.

DREDGING, QUAY WALL, ETC.—Brooklyn, N. Y.—Bids are asked by the Bureau of Yards and Docks, Navy Department, Washington, D. C., until July 16, for dredging Whitney Basin and Wallabout Bay, for constructing quay wall between Dry Dock No. 1 and Main St., and for constructing quay wall, coal dock, all at the U. S. Navy Yard, Brooklyn, New York (three bids). Mordecai T. Endicott, Chf. of Bureau, Washington, D. C.

DREDGING.—Boston, Mass.—The following bids were received June 28 by the harbor and land commissioners for dredging in South Bay, as advertised in Engineering News, and either depositing the material within the harbor lines or at sea:

	First alternative.	Second alternative.
Pan-American Dredging Co., Boston..	$29,987	$33,500
Eastern Dredging Co., Boston.........	43,650	43,894
International Contracting Co.........	43,500	38,000
Albert Hussey, New York............	36,118	36,148

CONTRACT PRICES.

SEWERAGE SYSTEM.—Mercer, Pa.—G. B. Zahniser, Engr., Clendenin Block, New Castle, Pa., informs us that the following bids were received June 27, 1898, for a sewerage system for the east side, as advertised in Engineering News; minimum grade, 50%; maximum grade, 22%; Cy. Clk., J. M. Campbell:

	Pipe, a ft.						
	Sewer, laid.			Iron.			
Bidder.	6-in., 10,700 ft.	8-in., 1,300 ft.	10-in., 565 ft.	36 ft.	Flushtanks, 3, each.	Manholes, 3, each.	Lampholes, 19 each.

*Awarded contract for Park brick.

ASPHALT PAVING.—Newark, N. J.—The Newark Asphalt Paving & Construction Co. has been awarded the contract for 20,000 sq. yds. of asphalt paving, at $1.41.

CEMENT SIDEWALK.—Milwaukee, Wis.—D. W. Cutter has been awarded the contract for 5,350 sq. ft. of cement sidewalk, at 10⅞ cts. a ft., and for 550 ft. of combination cement curb and gutter, at 36 cts. a ft.

DREDGING.—Philadelphia, Pa.—It is stated that the International Contracting Co., Syracuse, N. Y., has been awarded the contract for removing a ledge and for dredging in the Schuylkill River between Yankee Point and 58th St., at $5 and 33¾ cts. a cu. yd., respectively. In both cases the material is to be placed above high water mark within the city limits; and for ledge rock deposited where directed by the department, $5.50 a yd; total, $33,000.

ASPHALT PAVING.—Newark, N. J.—The board of public works awarded to the Newark Paving & Construction Co., the contracts for asphalt paving in two streets, at $1.41 a sq. yd., and in two other streets, at $1.45 a yd.; last year similar work was contracted at $2.35 a yd.

MAIN SEWER.—Allegheny, Pa.—A. V. Purnell has been awarded the following contract for constructing a main sewer in East St.: 1,030 ft. of 24-in. pipe sewer, $2.05 a ft.; 1,050 ft. of 20-in. pipe sewer, $1.55 a ft.; 1,120 ft. of 18-in. pipe sewer, $1.05 a ft.; 5,550 ft. of 9-in. connections, 30 cts. a ft.; 14 No. 1 inlets, $25 each; 16 manhole shafts, $18 each. Total, $7,218. Chas. Geyer, Mayor; Robt. Dilworth, Cy. Clk.

ASPHALT PAVING.—Allegheny, Pa.—The following contract for asphalt paving in Page St. was let to the Sicilian Asphalt Paving Co. June 20, 1898; 1,000 cu.yds. excavation, 50 cts. a yd.; 1,700 sq. yds. sheet asphalt paving, $1.80 a yd.; 1,100 sq. yds. brick sidewalk, 55 cts. a yd.; 1,000 lin. ft. curbing, 45 cts. a ft.; 50 lin. ft. crossing, reset, 15 cts. a ft.; 50 cu. yds. masonry, $4.75 a yd. Total, $4,860.

ARTESIAN WELL.—Casselton, N. Dak.—E. G. Guthrie, Audr., writes us that the following bids were received June 6 for sinking an artesian well: F. M. Wheeler, Casselton, $1.00 a ft. for 550 ft. of galvanized pipe; C. May, 95 cts. for 350 ft.

BLOCK PAVING.—Allegheny, Pa.—The following contract has been let by the council to the Kreps Coal & Sand Co. for Ligonier block paving in Overlook St.: 1,500 cu. yds. excavation, 37 cts. a cu. yd.; 1,450 sq. yds. Ligonier block paving, $1.52 a yd.; 830 sq. yds. vitrified brick sidewalk, 45 cts. a sq. yd.; 1,000 lin. ft. curbing, 45 cts. a ft.; 300 lin. ft. crossing stone, 65 cts. a ft.; 150 cu. yds. masonry, $3.95 a yd.; 20 lin. ft. iron fence, $1.00 a ft. Total, $4,390.

ASPHALT PAVING.—Rochester, N.Y.—The following bids were received by the executive board June 14, 1898, for asphalt paving in Linden and Yale Sts., estimated cost, $20,850; contract awarded Warren-Scharf Asphalt Paving Co.:

Quantities.		Warren-Scharf Asp. Pav. Co., $18,524.	Whitmore, Rauber & Vicinus, $18,821.	Rock Asp. Pavement Co., $18,864.	Rochester Vulcanite Pavmt Co., $18,866.

GRADING, ETC.—Cohoes, N. Y.—The following bids were received last week for grading in several streets: Eveline & Denallo, Waterford, N. Y., hard rock, $1 a cu. yd.; loose rock, 50 cts.; earth, 29 cts. John W. Flynn Waterford, solid rock, $1.15; loose rock, 95 cts.; earth, 34 cts. Houlihan & Larkin, solid rock, 90 cts.; loose rock, 64 cts.; earth, 30 cts. A. H. Hildreth, solid rock, 62 cts.; loose rock, 30 cts.; earth, 15 cts. Warner & Madigan, Mechanicsville, N. Y., solid rock, 94 cts.; loose rock, 57 cts.; earth, 33 cts.

BRICK PAVING.—Troy, N. Y.—M. J. Jackson & Son have been awarded the contract for paving 9th St. with Mack brick, at $1.94 a sq. yd.; total cost, $21,400.

ENGINEERING MATERIAL PRICES.

TRACK MATERIALS—

New York—Angle bars, 1.05 cts. to 1.10 cts.; spikes, 1.40 cts. to 1.50 cts.; track bolts, hexagonal, 1.80 cts. to 1.85 cts.; square, 1.60 cts. to 1.75 cts.

Chicago—Angle bars, 1.15 cts. to 1.25 cts.; spikes, 1.50 cts. to 1.60 cts.; track bolts, hexagonal, 1.90 cts. to 2.00 cts.; square, 1.80 to 1.90 cts.

RAILS, STEEL—

New York, new, $18.00 to $19.00; old iron, $11.00 to $11.50; old steel $9.00.
Chicago, new, $20.00 to $22.50; old iron, $12.25 to $12.50, steel, $10.50 to $11.00.
Pittsburg, new, $18.00; old iron, $13.50; steel, $10.50.

STRUCTURAL STEEL—

New York—Beams, 1.30 cts. to 1.35 cts.; channels, 1.30 cts. to 1.35 cts.; tees, 1.35 cts. to 1.40 cts.; angles, 1.15 cts. to 1.20 cts.; plates, 1.20 cts. to 1.30 cts.; rivets, iron, 2.25 cts. to 2.50 cts.; steel, 1.75 cts. to 1.85 cts.; universal mill plates, 1.15 cts. to 1.20 cts.; tank, 1.25 cts. to 1.30 cts.; shell, 1.25 cts. to 1.30 cts.; flange, 1.60 cts. to 1.75 cts.; firebox, 2.25 cts. to 2.50 cts.

Chicago—Beams, 1.30 cts. to 1.35 cts.; channels, 1.30 cts. to 1.45 cts.; tees, 1.35 cts. to 1.40 cts.; angles, 1.20 cts. to 1.25 cts.; universal mill plates, 1.25 cts. to 1.30 cts.; tank, $1.10 cts. to 1.20 cts.; shell, 1.45 cts. to 1.55 cts.; flange, 1.20 cts. to 1.40 cts.; firebox, 1.85 cts. to 5.00 cts.

Pittsburg—Beams, 1.15 cts. to 1.25 cts.; channels, 1.15 cts. to 1.25 cts.; tees, 1.20 cts. to 1.20 cts.; angles, 1.05 cts. to 1.15 cts.; universal mill plates, 1.00 cts. to 1.10 cts.; tank, 1.10 to 1.15 cts.; shell, 1.15 cts.; flange, 1.10 cts. to 1.20 cts.; firebox, 2 cts. upward.

MERCHANT STEEL—

Machinery, per lb., 1.60 cts. to 1.70 cts.
Cast, best in small lots, per lb., 7 cts.
Sheet, per lb., 8.5 cts.

IRON—

Pig Iron:

New York, No. 1, $11.00 to $11.50; No. 2, $10.75 to $11.00.
Chicago, No. 1, $11.50 to $12.00; No. 2, $11.00 to $11.50.
Pittsburg, No. 1, $10.40 to $10.50; No. 2, $10.00 to $10.25.

Bar Iron:

New York, common, 1.08 cts. to 1.15 cts.; refined, 1.15 cts. to 1.20 cts.
Chicago, common, 1.05 cts. to 1.10 cts.; refined, 1.10 cts. to 1.20 cts.

Sheets:

American, per lb., 4 cts. to 4½ cts.
Russia, per lb., 10¼ cts. to 10½ cts.

LUMBER—

New York:

Hemlock timber, 20 ft. and under, per M, $12.00 to $12.50.
Piling, Eastern spruce, 35 to 40 ft., 30 to 40% 12-in. butts, 4¼ cts. to 4½ cts.
Spruce, special cargoes, per M, $15.00 to $17.50.
Yellow pine, random cargoes, $14.50 to $17.00.
North Carolina pine, $2.25 to $2.40 advance over Norfolk rates.

San Francisco:

Oregon pine, per M, $15.50 to $17.50.
Redwood, per M, $17.00 to $19.00.
Redwood tank stock, up to 10 ft., $21.00 to $24.00.

GENERAL MATERIALS—

Lead, New York, 3.75 cts. to 3.80 cts.
Nails, Pittsburg, 1.40 cts.
Solder, per lb., 9 cts. to 11½ cts.
Spelter, per lb., 4.00 cts. to 4.50 cts.
Copper, ingots, 11.50 cts. to 12.00 cts.
Granite, rough, New York, cu. ft., 40 cts. to 50 cts.
Limestone, New York, cu. ft., 70 cts. to 80 cts.
Ohio freestone, New York, cu. ft., 85 cts. to 90 cts.
Slate, Penn. block, per square, $4.00 to $5.00.
White lead, American, per lb., 5½ cts. to 6 cts.
Lime, common state, per bbl., 70 cts.

* * *

INDUSTRIAL NOTES.

THE AMERICAN PIPE & FOUNDRY CO., Chattanooga, Tenn., has appointed Mr. Lester E. Wood, 100 Broadway, New York, Eastern Sales Agent.

CRAGE & TENCH, 61 Terrace, Buffalo, N. Y., have the contract for the Millstone extension of the Tionesta Valley Ry., running south from Sheffield, Pa.

THE TURNER ENGINEERING CO., Marion, O., has received an order for two 100-HP. Turner water tube boilers for a college building in Philadelphia.

THE W. S. DICKEY CLAY MFG. CO., Kansas City, Mo., has a contract for 300 carloads of sewer pipe for use in Guadalajara, Mex., at a cost of $80,000, according to report.

THE NILES TOOL WORKS, Hamilton, O., is reported to have purchased a large interest in the Pond Machine Tool Co., Plainfield, N. J. The companies will not be consolidated, but it is said that there will be a co-operation by which the shipping and other like expenses will be reduced. It is also reported that the new tool works in Berlin, Germany, to be known as the Deutsche Niles Werkzeng Machinen Fabrik, will be owned by these two companies.

THE WESTINGHOUSE ELECTRIC & MFG. CO., Pittsburg, is reported to have a contract from the Anniston Consolidated St. Ry., Anniston, Ala., for electrical machinery for the operation of the road, amounting to about $350,000. The contract includes over 200 Westinghouse street railway motors and two large dynamos. A contract has also been received, it is stated, from the Consolidated St. Ry., Baltimore, Md., for 60 Westinghouse street railway motors, at a cost of $50,000.

THE D. A. TOMPKINS CO., Charlotte, N. C., has closed a contract, through Guthrie & Rockwood, Buffalo, N. Y., engineers, for a sewage disposal plant on Waring's system of forced bacterial oxidation, to be installed at the Western Refuge for Women, Albion, N. Y. The plant will have a capacity of 25,000 gallons a day, but, it is claimed, purifies the sewage to the standard of drinking water, the effluent being discharged into a small brook which otherwise is dry in summer. Mr. W. L. Church, 282 Manhattan Ave., is the Resident Engineer of the company in New York.

THE JOSEPH DIXON CRUCIBLE CO., Jersey City, N. J., has placed on the market a solid belt dressing in round bars, about 8 ins. long and 2 ins. in diameter, making a package convenient to the hand and easy to apply even to fast running belts. It is not claimed that this solid dressing is as good a preservative of the life and elasticity of the belt as the Dixon paste, as the object has been to meet the demand for a more convenient form of belt dressing and one which may be quickly applied.

THE BERLIN IRON BRIDGE CO., East Berlin, Conn., has designed and is erecting for the Syracuse Construction Co., Syracuse, N. Y., new buildings in connection with its electric railway plant, consisting of a fireproof boiler house, 60 × 90 ft., having steel framework covered with corrugated iron on the sides and roof; an engine room 65 × 80 ft., with a steel frame and brick sides, and a car-barn and repair shop, 65 × 170 ft., of steel framework construction, with corrugated iron sides.

THE GENERAL ELECTRIC CO., Schenectady, N. Y., at a directors' meeting last week, voted to recommend to the stockholders a reduction in the share capital of the company, both common and preferred, of 40%, so that each holder of one hundred shares of present stock will get 60 shares of the new. On the basis of the new capitalization $1,275,000 will be required annually to pay 7% upon the preferred stock and 6% upon the common stock. A stockholders' meeting will be held Aug. 10, at noon, in Schenectady.

THE VULCAN IRON WORKS CO., Toledo, O., has recently secured several large orders and is about to ship five steam shovels to Ogdensburg, N. Y., for use in constructing a large water trench, 40 ft. deep, 150 ft. wide and 4 miles long, with a fall of 60 ft., which taps the St. Lawrence River and is then turned into Grass Creek. This work is being done by an English syndicate, at a cost of $2,000,000. Among other orders are two steam shovels for use in phosphate beds near Charleston, S. C., where several have been previously shipped; also a shovel to the Northwest and one to Pittsburg.

THE BOSTON & LOCKPORT BLOCK CO., 142 Commercial St., Boston, through its President, Mr. Albert D. Bosson, together with the Treasurer, Mr. Myron H. Tarbox, constituting a majority of the Executive Committee, has purchased from the assignees of the Bagnall-Loud Block Co., a Maine corporation, organized in 1894, of which Mr. Robert M. Barnard was President, and Mr. Herbert Loud, Treasurer, all the latter's stock, manufactured and in process, and the machinery, patterns, etc. The finished stock will be at once removed to the store and the balance to the factory at East Boston.

ANDREW J. MORSE & SON, 138 and 140 Congress St., Boston, Mass., report that their diving apparatus, complete for two divers under one pump, has been made the official standard by the Navy Department and sample sets are kept at all naval stations. Since the "Maine" disaster they have supplied what are claimed to be the largest requisitions ever issued by the government for diving apparatus and have delivered and have under construction about 75 sets of the new standard style. They have also supplied their "U. S. Navy" outfits to the new Japanese cruisers "Chitose" and "Kasagi," and for the past three months have been forced to work night and day, including Sundays, to meet the demands of the Navy Department.

THE S. FLORY MFG. CO., Bangor, Pa., has been running its works day and night since last November to keep up with orders for its hoisting engines and suspension cableways. Recently several carloads of engines have been shipped, including one for export to Kobe, Japan, and two carloads of dredging machinery and one of portable hoisting engines to Boston, Mass. The demand for hoisting and conveying machinery has made necessary an increase in the working capacity of the plant. Within the past few months the company has erected four cableways, among them being one for the Empire State Granite Co., Pochuck, N. Y. The quarry is on a hill, about 400 ft. above the yard and railway, and the cableway has a clear span of 900 ft. between the towers, with an individual load capacity of 15 tons. The plant is operated by a 75-HP. Flory special cableway hoist, fitted with two friction drums, and reversible link motion and an 80-HP. boiler of the locomotive type. Formerly the stone was handled by swinging it from derrick to derrick until the yard was reached, which was laborious, slow and expensive. With the cableway the stones are conveyed at a speed of 700 ft. a minute, if desired.

THE AMERICAN WHEELOCK ENGINE CO., Worcester, Mass., and Postal Telegraph Bldg., New York, reports the following recent installations of the Greene-Wheelock engine: Six 1,500-HP., with rope dirves, Chicago City Ry.; one 600-HP. single-cylinder condensing, Worcester (Mass.) wire mill; one 200-HP., Hammond-Reed Co., Worcester, Mass.; one 1,000-HP., B. B. & R. Knight, Providence, R. I.; one 550-HP. single-cylinder and one 550-HP. cross-compound, with rope drives, Syracuse Construction Co., Syracuse, N. Y.; one 400-HP., Willamette Pulp & Paper Co., Oregon City, Ore.; one 300-HP. and one 350-HP., Pejepscot Paper Co., Brunswick, Me.; one 750-HP. direct-connected, New York Heat, Light & Power Co., New York; three 350-HP. direct-connected, J. G. White & Co., New York; two 500-HP. cross-compound, direct-connected, Potomac Electric Power Co., being the second order; the previous order being for two 750-HP. direct-connected engines. The company has installed at the Grosvenordale electric light plant, Grosvenordale, Conn., the high-pressure side of a cross-compound engine, putting its cylinder and valve gear onto a Corliss bed and replacing Corliss cylinders. This is the second Corliss engine in that plant that has been replaced with the Greene-Wheelock cylinder and valve gear. The company is now building for the Bibb Mfg. Co., Macon, Ga., the high-pressure side of a 750-HP. cross-compound, the low-pressure side to be a Greene-Wheelock, low-pressure cylinder with valve gear, replacing the present Corliss cylinder and valve gear.

NEW COMPANIES.—Belvedere Brewing Co., Harpers Ferry, W. Va.; $80,000, commencing with $40; August Kruger, Jacob Schafer, Henry Schafer and Eva Schafer, Harpers Ferry; Elias Hiney, Charlestown, W. Va.

Independent Telephone Co., Lititz, Pa.; $25,000; to operate lines in Lancaster, Berks and Lebanon counties; Israel G. Erb, H. R. Landis, A. M. Amer, P. B. Bucher and A. B. Long, Lititz; E. B. Brubaker, Lexington, Pa.; S. B. Erb, Millway, Pa.; E. L. Garber, Stevens, Pa.; S. W. Buch, Kissel Hill, Pa.; M. L. Weidman, Ephrata, Pa.; Jacob Mace, Reamstown, Pa.; Philip F. Ruhl, Brickerville, Pa.; A. E. Lane, Brunnerville, Pa.

Citizens' Telephone Co., Cambridge City, Ind.; $10,000; James A. Boyd, John W. Marson, John R. Mauk, Horace B. Boyd, Conrad B. Keller, Cornelius T. Wright, George Bridenbucker, Albert W. Bradbury and Wm. B. Barefoot.

Atlantic Coast Telephone Co., Atlantic City, N. J.; $100,000; Edwin L. Reinhold, of Marietta, Pa., and Lewis Kuehnie and James B. Reiley, of Atlantic City.

Pittsburg & Allegheny Telephone Co., of Pittsburg, Pa.; to build a telegraph line in Allegheny county for police and fire alarms and messenger business; L. H. Matthews, John F. Freeman, Pittsburg; John Phelps, Baltimore, Md.

Rural Telephone Co.; $3,000; to maintain a telephone line connecting various towns in Westchester county; Pres., R. S. Haviland; Samuel Thompson, and Treas., C. W. Page, of Chappaqua, N. Y.; W. H. Moore, H. E. Washburn; Secy., G. G. Norton and T. B. Pierce, of Pleasantville, N.Y.

Hicksville Telephone Co.; $10,000; to operate a telephone system at Hicksville, O.; Ed. L. Barber, Frank B. Ufer, W. A. Barber, C. E. Brigham and J. C. King.

Star Mfg. & Chemical Co., Syracuse, N. Y.; $1,000,000, commencing with $50; to conduct a general commercial business; G. O. Chilton, Chas. W. Shith, D. M. Black, C. H. Carwithin and H. H. White, all of Charleston, W. Va.

Henry W. Belcher Co., Jersey City, N. J.; $100,000. commencing with $1,000; to manufacture iron, steel, brass, etc.; James W. Newton, John J. O'Brien and Henry W. Belcher, all of 243 Washington St., Jersey City.

Pridham Sewerage Utility Co., Newark, N. J.; $100,000, commencing with $5,000; to treat and deodorize all kinds of sewerage; Samuel S. Pridham, Paul Buchanan and Ludwig F. Mergott, of Newark; John Whitehead, Morristown, N. J.

General Electric Automobile Co., Philadelphia, Pa.; $2,500,000, commencing with $2,500; to acquire electrical appliances and to do a general manufacturing business; A. B. Pearson, Clarence E. Lent, J. E. Lewis, T. R. Heller and C. W. Cox, all of Philadelphia.

Asphalt and Rubber Supply Mfg. Co., New York; $600, commencing with $50; to manufacture insulating materials, etc.; W. C. Snell, N. J. Hatcher, A. F. Vickers, D. M. Black and A. C. Gunther, all of Charleston, W. Va.

U. S. Steel Cement Co., New York; $1,000,000, commencing with $2,500; to manufacture and sell cement; Geo. F. Averill and Everett Clapp, New York; H. F. Cook, Sag Harbor, New York; Wm. B. Hill and Alexander Cameron, Brooklyn, N. Y.

Mohawk Mfg. Co., Cincinnati, O.; $1,000,000, commencing with $5,000; to conduct a general manufacturing business; G. F. Klotter, Wm. C. Tieman, Geo. H. Stout, E. L. Dillinger and W. M. Berry, all of Cincinnati.

Automatic Incubator Co., Philadelphia, Pa.; $1,000,000, commencing with $1,000; A. A. Freeman, J. K. Freeman, D. L. Busby, Geo. R. Morehouse and Ogden Armstrong, all of Philadelphia.

Frictionless Bearing Co., New York; $1,000,000, commencing with $1,000; to manufacture and deal in bearings; Geo. P. Smith and Chas. L. Turey, New York; James Sawyer, Jr., Stamford, Conn.; Alexander Cameron and Wm. B. Hill, Brooklyn, N. Y.

McManus Contracting Co., Bordenton, N. J.; $25,000, commencing with $5,000; to construct bridges, buildings, etc.; Michael McManus, 1416 Tioga St., and Louis P. Riedenauer, 2336 Jefferson St., of Philadelphia, Pa.; John H. Ayres, Bordenton.

United States Battery & Electrical Mfg. Co., Jersey City, N. J.; $100,000, commencing with $1,000; to manufacture storage batteries, motors, etc.; Conrad N. Jordan and Louis Lieber, New York; W. M. McDougall, East Orange, N. J.

Empire State Rubber Shoe Co., New York; $300,000, commencing with $50; R. W. Fowler, Wm. A. Towner, Frederick Ferris, J. E. Fryer and Darwin Rudd, all of New York.

United States Ball Bearing Co., Elkins, W. Va.; $1,000,000, commencing with $2,500; to manufacture all kinds of anti-friction devices; J. J. Humphill and C. M. Fulton, Washington, D. C.; B. F. Taylor, Elkins; J. D. Richerson, Murfreesboro, Tenn.; W. A. Jones, Warsaw, Va.

Writing Machine Co., New York; $500,000, commencing with $50; to manufacture and deal in typewriting machines and parts thereof; J. T. Williams and N. H. Lucken, Brooklyn, N. Y.; H. F. Frevert, J. M. Creary and Ida C. White, New York.

Compressed Steel Co., 22 Clinton St., Newark, N. J.; $400,000, commencing with $1,000; to manufacture steel, etc.; Henry Dickson and Peter Hassinger, Newark; A. H. Ryan, Chas. F. Spaulding, Frank R. Wickes, A. A. Richmond and Edward E. Bruen, East Orange, N. J.

James P. McDonald Contract Co., 83 Montgomery St., Jersey City, N. J.; $10,000, commencing with $1,000; to build and repair railways, etc.; Frederick Dwight, 10 Wall St.; Frank E. Randall, 80 Broadway, both of New York; John J. Treacy, 446 Third St., Jersey City.

Acme Portland Cement Co., 419 Market St., Camden, N. J.; $1,000,000, commencing with $1,000; to manufacture cements of all kinds; T. H. Wheeler, Orange, N. J.; Wm. M. McKeloy, John Marshall Lockhart, and Chas. E. Pope, of Pittsburg, Pa.

Boston & Costa Rica Land & Investment Co., Jersey City, N. J.; $100,000, commencing with $21,000; H. F. Hatch, William Fillingham and E. G. Maturin, 60 Grand St., Jersey City.

Philadelphia Big Four State Syndicate, Camden, N. J.; $50,000, commencing with $3,000; to quarry slate, stone, etc.; Peter M. Mathieu, J. Wm. Mathieu, Henry A. Mathieu and Geo. H. B. Martin, 419 Market St., Camden, N. J.

Harry C. Nichols Co., Camden, N. J.; $25,000, commencing with $1,000; deal in real estate, and to build houses, water-works, etc.; Wm. S. Darnell, Camden; Joseph L. Dailey and Harry C. Nichols, Philadelphia, Pa.

Cory Tidewater & Improvement Co., Jersey City, N. J.; $100,000, commencing with $50,000; to build docks, wharves, etc.; Herbert D. Cory, David U. Cory and Stuart Lyman, all of Englewood, N. J.

Cleveland Electric Co., Cleveland, O.; $75,000, commencing with $450; to manufacture and deal in all kinds of electrical devices; Wm. P. Bowman, F. C. McMillin, J. E. Mathews, F. W. Root and N. C. Stevens, all of Cleveland.

Rapid Transit Construction Co., New York; $5,000,000, commencing with $1,000,000; to build a rapid transit railway in the Borough of Manhattan; J. W. Reno, I. P. Smith, J. D. Adams, J. B. Bissell and C. A. L. Massie, all of New York

Wilson Mfg. Co., New York; $35,000, commencing with $60; to manufacture and sell scales, tug links, etc.; E. K. Barber, Keesville, N. Y.; R. P. Wilson, East Orange, N. J.; R. E. Oatman, John Leighton and W. W. Tucker, New York.

Miller Car Refrigerating Co., Charleston, W. Va.; $250,000, commencing with $5,000; to build and equip refrigerator cars; G. D. James, Thomas Watson, E. W. Small and E. D. Poor, New York; C. S. Miller, Tiffin, O.

Fairmont Glass Works, Fairmont, W. Va.; $50,000, commencing with $5,500; to manufacture glass, etc.; Z. G. Morgan, J. M. Hartley, J. M. Crane, O. S. McKinney, and M. L. Hutchinson, all of Fairmont.

Linomatrix Co., Washington, D. C.; $5,000,000, commencing with $50; to deal and own letters patent pertaining to matrix-making, lino-typing, stereotyping, etc.; Stilson Hutchins, E. V. Murphy and O. T. Moore, Washington; J. O. Clephane and Andrew Devine, New York.

New York Finance & Construction Co., Jersey City, N. J.; $100,000, commencing with $25,000; to conduct a general construction business; Lee W. Woolston, 141 Broadway, New York; Geo. F. Woolston, Arlington, N. J.; Geo. F. Woolstron, Jr., Pittsburg, Pa.

INDUSTRIAL NOTES. 16

PERSONAL.

Mr. C. L. Brinser, of Harrisburg, Pa., has been appointed Superintendent of the Greensburg, Jeanette & Pittsburg Electric St. Ry.

Mr. Frederick J. Mills, C. E., State Engineer of Idaho, has been commissioned First Lieutenant in the Second Regiment of United States Volunteer Engineers.

Mr. H. R. Sanford, Civil Engineer, U. S. Navy, has been detached from the Bureau of Yards and Docks, Washington, D. C., and ordered to the navy yard, Boston, Mass.

Mr. E. Sherman Gould, M. Am. Soc. C. E., has returned to Yonkers, N. Y., from Tampa and Jacksonville, Fla., where he has been for the last two months at Army Headquarters.

Mr. James R. Lawrence has been appointed City Engineer of Greenville, S. C., to succeed Mr. A. W. Edens, resigned. Mr. Lawrence has already held the office several times.

Prof. Harris J. Ryan, M. Am. Soc. M. E., Professor of Electrical Engineering in Sibley College, Cornell University, Ithaca, N. Y., sailed for Europe June 27, accompanied by his wife.

Mr. W. J. Mallor has been appointed Assistant Superintendent of Bridges and Buildings of the Southern Pacific Ry., with headquarters at Algiers, La., to succeed Mr. C. C. Mallard, promoted.

Mr. John Hays Hammond, mining engineer, formerly of South Africa, has been appointed Consulting Engineer to the Russian Government, which is about to develop rich government mines in the Ural Mountains.

Prof. George F. Becker, of the United States Geological Survey, is reported to have been sent by the government to the Philippines to make a general examination of the islands, including their mineral resources.

Mr. George A. Kimball, M. Am. Soc. C. E., member of the Metropolitan Sewerage Commission, Boston, Mass., has been appointed by the city council of Barre, Vt., as a member of the commission to fix the price of the water-works which the city proposes to purchase.

Mr. E. B. Sturges has been elected President of the New York, Wyoming & Western R. R. The other officers are: Mr. L. A. Watres, Vice-President and General Manager; Mr. T. H. Watkins, Treasurer; Mr. Thos. E. Jones, Secretary, and Mr. Edward L. Jenks, Chief Engineer.

Mr. R. P. Bower, City Engineer, of Champaign, Ill., has been appointed Second Lieutenant in the United States Army, his name, it is stated, being one of the three highest on the army register for proficiency in the study of military science at the University of Illinois.

Mr. John Alexander McDonald, M. Inst. C. E., M. Inst. M. E., M. Am. Soc. C. E., Assistant Engineer in Chief of the Public Works Department of Western Australia, in charge of the Fremantle Harbor Works, still continues to hold that office, newspaper reports to the contrary notwithstanding.

Mr. E. D. Dorchester, Secretary and Assistant General Manager of the Velasco Terminal Ry., with headquarters at Velasco, Tex., has been appointed General Manager, to succeed Mr. L. L. Foster, who has resigned to accept the office of President of the Agricultural and Mechanical College of Texas, College Station, Tex.

Mr. Richard P. Rothwell, M. Am. Inst. M. E., M. Am. Soc. C. E., Editor of the "Engineering and Mining Journal" and of "The Mineral Industry," has been awarded a gold medal by the Societe d'Encouragement pour l'Industrie Nationale of France in consideration of the services rendered to industry by the publication of the latter work.

Mr. A. B. Dunning, civil engineer, has been made the Manager of the Dunning Engineering & Construction Co., Scranton, Pa. Mr. O. D. Shepard, civil engineer, of Scranton, and Col. George E. Waring, Jr., M. Inst. C. E., formerly Street Commissioner of New York city, have been appointed consulting engineers to the company. The latter will act as its New York representative.

Mr. N. C. Grover has been appointed Professor of Civil Engineering in the University of Maine, Orono, Me., to succeed Prof. Geo. H. Hamlin, whose resignation is noted in this issue. Mr. C. P. Weston has been appointed Instructor in Civil Engineering, Mr. Ralph Hamlin, Assistant in Civil Engineering, and Mr. R. H. Mansen, Assistant in Electrical Engineering. Lieut. Herbert N. Royden, U. S. Army, Military Professor, has been ordered to duty as aide-de-camp on the staff of Brig.-Gen. Charles P. Mattocks, U. S. Volunteers.

Mr. J. Francis Le Baron, M. Am. Soc. C. E., of Jacksonville, Fla., has been appointed Chief Engineer of the American Honduras Co., and expected to leave for Honduras July 14 to make physical surveys and examination, with plans and estimates, for building jetties at the mouth of the Patuca River, improving it for navigation, building wharves, warehouses and a railway from the head of navigation to the capital. It is expected that construction will commence immediately after the plans and reports are finished. The company has a valuable concession from the Honduras government.

Mr. Robert C. Barnard, Assistant Engineer of the Chicago Division of the Pennsylvania Lines West of Pittsburg, with headquarters at Logansport, Ind., has been appointed Engineer of Maintenance of Way of the Richmond Division, with headquarters at Richmond, Ind., to succeed Mr. Robert K. Brown, Jr., Assoc. M. Am. Soc. C. E., resigned. Mr. Robert Ferriday, of the engineering department of the Erie & Ashtabula Division, with headquarters at Lawrence Junction, Pa., has been appointed to succeed Mr. Barnard at Logansport. Mr. D. B. Johnston, Assistant Engineer, with headquarters at Lawrence Junction, has been appointed Engineer of Maintenance of Way of the Cincinnati & Muskingum Valley Division, an office for some time vacant. Mr. Paul Jones has been appointed Engineer of Maintenance of Way of the Indianapolis & Vincennes Division.

Prof. George Herbert Hamlin, M. Am. Soc. C. E., Professor of Civil Engineering in the University of Maine, Orono, Me., has resigned, to devote himself to his private business. He was born in Sidney, Me., and graduated from the Maine State College, now the University of Maine, in 1873, being appointed Tutor in Civil Engineering. He held various positions in the university until 1880, when he was made Professor of Civil Engineering, and has held it continuously ever since. For a time he was also City Engineer of Bangor, and he has been consulting engineer for various manufacturing companies. Besides being a member of the American Society of Civil Engineers, to which he was elected July 3, 1895, he is also a member of the American Society for the Promotion of Engineering Education and of the Boston Society of Civil Engineers. On June 27 a supper was tendered to him by Dr. A. W. Harris, President of the university, all the faculty participating.

OBITUARY.

Mr. James Devlin, contractor, of Elizabeth, N. J., died July 4, aged 72.

Mr. Henry D. Fisher, contractor, of Reading, Pa., died July 6, aged 66.

Mr. Charles O. Richardson, Treasurer of the Worcester Construction Co., Worcester, Mass., died July 7, aged 65.

Mr. John De Noyelles Christie, civil engineer, Road Engineer of Rockland County, New York, died at his home, Haverstraw, N. Y., July 2, aged 68.

Mr. Louis R. Townsend, architect, of San Francisco, Cal., died July 6, aged 67. He was the senior member of the firm of Townsend & Wyneken.

Mr. Archalous Wyckoff, the inventor of the Wyckoff paving block, extensively used in this country and Canada, died at Elmira, N. Y., July 6, aged 82.

Mr. B. H. Nelson, Water Commissioner of Granville, N. Y., was killed by the caving-in of a trench in that place, July 10, while engaged in inspecting a water main. He was 50 years of age.

Mr. Andrew Brown, bridge contractor, of Baltimore, Md., died July 5, aged 71. At the time of his death he was the President of the Broadway & Locust Point Steam Ferry Co., of Baltimore.

Mr. D. J. Thayer, Vice-President and Secretary of the Fulton County Narrow Gage Ry., with headquarters at Chariton, Ia., died at Mercy Hospital, Burlington, Ia., June 21. Mr. J. D. Temple, formerly Auditor of the same road, died at Des Moines, Ia., June 24.

Mr. Joseph Curtis Platt, M. Am. Soc. C. E., died at Waterford, N. Y., July 7. He was born in Fair Haven, Conn., Jan. 9, 1845, and was graduated as a civil engineer from the Rensselaer Polytechnic Institute, Troy, N. Y., in 1866. He was a consulting engineer, chiefly engaged in water-works design and construction, and was also a Member of the American Institute of Mining Engineers, the American Society of Mechanical Engineers and of the University and Engineers' Clubs of New York.

Capt. Edward Shanley, of the firm of Shanley & Ryan, contractors, died in New York on July 9. Mr. Shanley was born at Hunter, Greene Co., N. Y., about 64 years ago, and served during the Civil War in the 9th New York Volunteers and attained the rank of Captain. As a contractor he was engaged in bridge work for the West Shore, Erie and Canadian Pacific railways; he also built Sections 22, 23 of the New Croton Aqueduct, and did work for the West Indian Improvement Co. in Jamaica. At the time of his death his firm was building the New York anchorage of the new East River bridge.

Mr. Francisco Javier Cisneros, M. Am. Soc. C. E., Managing Director of the Barranquilla Ry. & Pier Co., with headquarters in London, England, died July 7 of Bright's disease at the Windsor Hotel, New York city. He was born in Santiago de Cuba in 1836, and graduated from the School of Engineering, in Havana, finishing his technical education in the Rensselaer Polytechnic Institute, Troy, N. Y. He was then engaged by an English syndicate to build railways in Cuba, and was one of the promoters of the revolution of 1868, placing his fortune at the disposal of the cause of Cuban freedom. In 1874, having thus impoverished himself, he went to Colombia, where he superintended some important engineering works and again amassed a large fortune. At the outbreak of the present Cuban revolution he again offered his money and services to the Junta, and was in this country at the time of his death on an important secret mission.

Mr. Pedro Jose Sosa, M. Am. Soc. C. E., of Panama, Columbia, was one of the passengers lost on the ill-fated steamship "La Bourgogne," which was sunk in collision, July 4, off Sable Island, Nova Scotia. He was born in Panama, 45 years ago, and graduated from the Rensselaer Polytechnic Institute, Troy, N. Y., in 1873. He returned to his native country and practised his profession in Panama and Guayaquil. In 1879, while he was City Engineer of the former city, De Lesseps made his first visit to the isthmus, and on his return to Paris Mr. Sosa accompanied him as the Colombian delegate to the international congress of engineers, whose report was made the basis of the canal company's plan of operations. The French government made him a Chevalier of the Legion of Honor in 1880, and in 1884 he was elected a member of the American Society of Civil Engineers. He supervised the erection of the lighthouse near Colon, and was Chief Engineer of the Aqueduct at Panama. At the time of the disaster in which he lost his life, he was on his way to Paris to attend a conference of engineers which is to decide whether the completion of the Panama Canal project is practical.

Rear-Admiral Daniel Ammen, U. S. Navy, died at the Naval Hospital, Washington, D. C., July 11. He was born in Brown county, Ohio, May 15, 1820, and entered the U. S. Navy in 1836 as a midshipman. In 1853 he was in charge of a scientific expedition to the Paraguay River on the U. S. S. "Water Witch." During the Civil War he was executive officer of the "Roanoke," and was engaged in the battles of Port Royal and Tybee Island and the attacks against Fort McAllister and Fort Sumter. He was commissioned Commodore April 1, 1872, and Rear-Admiral Dec. 11, 1877, being retired in June of the following year at his own request. He had charge, in 1876, as a member of the Isthmian Canal Commission, of the survey for a canal to connect the Atlantic and Pacific, and endeavored to bring about the construction of the Nicaragua Canal at that time. He was sent to Paris to attend the Interoceanic Ship Canal Congress, which preceded the Panama Canal undertaking. He was the author of a number of naval treatises and the inventor of a number of appliances now used in the navy. In recent years he has been most widely known by his advocacy of the ram in naval warfare, and by the partial adoption of his ideas by the U. S. Navy in the ram "Katahdin." He was led to advocate the ram in naval warfare by the experiences of the Civil War with the "Merrimac" and other rams. His early plans were modified in accordance with the rapid development of warships and armament, and it was not until 1891 that a contract was awarded by the government for a ram upon his designs. The "Katahdin" has never yet had an opportunity to test her equipment in actual combat.

Dr. Cornelius Herz, of Panama Canal notoriety, died at Bournemouth, England, July 6. He was born in Besancon, France, Sept. 3, 1845, and came to the United States with his parents at an early age. He graduated from the College of the City of New York in 1864, and later received the degree of Master of Science from the same institution. He was sent to Heidelberg, Germany, to study medicine, and continued his professional education in Munich, Vienna and Paris. In 1870 he was appointed Assistant Surgeon-General to the Army of the Loire, and for services in the army he was decorated with the Cross of the Legion of Honor. At the end of the Franco-Prussian war he returned to New York and later went to San Francisco, where he soon became a member of the Board of Health. He founded the first electrical works in that city, and in 1877 returned to Paris, where he introduced the electric light, thus overturning the gas monopoly. He founded "La Lumiere Electrique" in that city, now one of the leading electrical journals of the world, and organized the telephone system of France. He was successively raised from the rank of Knight of the Legion of Honor, through the intermediate grades, to Grand Officer. In 1892, when the Panama bubble burst, Dr. Herz was charged with being implicated in the corruption of public officials in connection with that enterprise. He fled to London, where he was arrested on extradition papers, but owing to illness, which confined him to his bed from 1893 to 1896, he was unable to appear in court. On May 2, 1896, the charges against him having been declared to be invalid and unworthy of notice, he was released from custody. His property had been confiscated by the French government, and he demanded of that government as a citizen of the United States the sum of $5,000,000 indemnity. The claim was unsettled at the time of his death.

ENGINEERING SOCIETIES.

COMING TECHNICAL MEETINGS.

AMERICAN SOCIETY OF R. R. SUPERINTENDENTS.
July 13-14. Annual meeting, Alexandria Bay, N.Y. Secy., C. A. Hammond, Asbury Park, N. J.

AMERICAN HEATING AND VENTILATING SOCIETY.
July 15. Atlantic City, N. J. Secy., S. A. Jellett, 704 Arch St., Philadelphia, Pa.

ENGINEERS' CLUB OF MINNEAPOLIS.
July 18. Secy., H. E. Smith, 1620 S. E. 4th St., Minneapolis, Minn.
ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.
July 19. Secy., R. A. Fessenden, 410 Penn Ave., Pittsburg, Pa.
WESTERN FOUNDRYMEN'S ASSOCIATION.
July 20. Secy., B. M. Gardner, 1522 Monadnock Block, Chicago, Ill.
AMERICAN SOCIETY OF CIVIL ENGINEERS.
July 26 to 29. Annual convention at Detroit. Secy., C. W. Hunt, 220 W. 57th St., New York, N. Y.
WESTERN SOCIETY OF ENGINEERS.
Aug. 3. "Establishment of Street Grades," Chas. P. Chase. Secy., N. L. Litten, Monadnock Block, Chicago, Ill.
CIVIL ENGINEERS' CLUB OF CLEVELAND.
Aug 9. Secy., Wm. H. Searles, Case Library Bldg., Cleveland, O.

AMERICAN SOCIETY OF CIVIL ENGINEERS.—The Cleveland, O., members of the society have extended an invitation to the members attending the annual convention at Detroit on July 26 to participate in a special excursion on Lake Erie on July 25, the day before the convention. During the excursion visits will be made to special points of interest in the harbor, including the new piers and the steel crib and water-works tunnel now under construction. The headquarters for the day will be at the Weddell House, from which the excursion will start promptly at 2 o'clock p. m. Members can take either the night boat in the evening or the Lake Shore & Michigan Southern Ry. train in the morning and arrive at Detroit in time for the opening session of the convention.

NEW PUBLICATIONS.

LITERARY MAGAZINES.—Those of our readers whose memories go back to the days of the Civil War will recall the destruction of merchant shipping effected by the Confederate vessels "Tallahassee" and "Florida." The July "Century" contains an account of these two vessels and their eventful voyages written by the commander of the former vessel and by a midshipman aboard the latter. It is interesting to note that the latter vessel relied on sails as well as steam for speed, and her best record in a gale when she was making every effort to escape from a pursuing vessel was 13½ knots.

The "Atlantic Monthly" for July has two articles which deserve mention here, one by Mr. James Bryce on "The Essential Unity of Britain and America," and the other by Mr. Henry C. Lea on "The Decadence of Spain." In the July "Popular Science Monthly," Mr. E. J. Prindle writes on "Weather Forecasts," explaining the methods by which the United States Weather Bureau carries on its work. Many of the instruments used are illustrated and described, and the article is on the whole one of the best popular accounts of the Weather Bureau that we recall.

The "North American Review" opens with "An Object Lesson in Anglo-Saxon Rule: What Britain has done in Egypt," which is appropriate at this time when thoughtful Americans are looking forward to some problems with which this country will soon have to wrestle. "The Resources and Industries of Spain" are described by Mr. E. D. Jones in a short paper, which faithfully presents the barren and impoverished condition of much of that country, and the need of a stable government and popular education to bring about an improvement. In the same magazine is an article by Mr. F. B. Thurber, which appears to be a thinly disguised plea for the rehabilitation of the old Ramapo water scheme, by which a party of capitalists planned to secure a fat contract for furnishing an additional water supply to New York city, to be paid for at so much per gallon. The article does no credit to either Mr. Thurber or the magazine in which it is published. Still another article in the same magazine deserves a word of comment here. It is entitled "International Piracy," and advocates a change in international law under which merchant vessels of an enemy will be safe from capture. There is little doubt that such a change will eventually be brought about. On land the property of a non-combatant is respected in civilized warfare, and there is really little more reason why his property afloat should be confiscated. An article on a similar topic is found in the June "Contemporary Review," in which a writer advocates that the British Government in time of war should undertake to cover maritime war risks on merchant vessels under its flag. The most important article in this magazine, however, is by Dr. E. J. Dillon, entitled "The Ruin of Spain," and it is especially notable because the writer defends Weyler as Spain's ablest and most patriotic general. Dr. Dillon has evidently made a thorough study of Spanish politics, and his view of it is one with which few Americans are familar. The "Fortnightly" for June contains an article on "Cuba and Her Struggle for Freedom," from the pen of our own Fitzhugh Lee, and the "Nineteenth Century" has a description of the methods adopted in fighting the bubonic plague in India, by Miss Marion Hunter.

RAILWAYS.

ALLEGHENY & WESTERN.—J. M. Floesch, Ch. Engr., Kittanning, Pa., informs us that the construction of this line is now under contract between Lindsey and Butler, 62 miles, as follows: To C. J. Ryan & Son, 43 West 33d St., New York, for 30 miles; to Thomas Collins & Co., of Bellefonte, Pa., 10 miles; to the Pennsylvania Construction & Improvement Co., Curwensville, Pa., for 22 miles. Contracts are being carried out all along the line, and it is expected to complete the grading by December. Jutte & Foley, of Pittsburg, Pa., have also been awarded the contract for the masonry work and about 9,000 cu. yds. of earthwork for the 1,500-ft. bridge to span the Allegheny River at Moss Grove. The contract for the superstructure of this bridge has not yet been let. A further extension of this railway from Butler to New Castle is contemplated, and it is expected that work will be completed by next June.

ALTOONA & PHILLIPSBURG CONNECTING.—Press reports state that the Harlan & Hollingsworth Co., Wilmington, Del., manufacturers of cars, has filed a bill in equity in the Philadelphia courts against the Altoona & Phillipsburg Connecting R. R. Co. and the Union Trust Co., trustees of the mortgage dated June 1, 1893, on the railway, property and franchises, securing an issue of bonds amounting to $400,000, asking for the foreclosure of the mortgage and the appointment of a receiver. The railroad is 18 miles long, running between Altoona and Phillipsburg, Pa., in the Clearfield coal district. Pres., Henry Levis, Drexel Bldg., Philadelphia, Pa.

ASTORIA & COLUMBIA RIVER.—T. H. Curtis, Ch. Engr., Astoria, Ore., informs us that this line is completed from Goble to Seaside, via Astoria, with a branch at Flavel, Ore., a distance of 81 miles. No extension is proposed. Pres., A. B. Hammond, Astoria.

CHESAPEAKE BEACH.—About 12 miles of grading is said to be completed on this new line between Washington, D. C., and Marlboro, Md., and work is to be carried 18 miles farther on to Chesapeake Beach. Green & Burrows, Atlantic Building, Washington, have the contract for grading. L. H. Hyer, Ch. Engr., Chesapeake Bay Construction Co., 1420 New York Ave., Washington, may be addressed.

CHICAGO TERMINAL TRANSFER.—F. E. Paradis, Ch. Engr., Chicago, Ill., informs us that this company is constructing an extension to its system from Franklin Park to Mayfair, Ill., seven miles. The right of way and the necessary capital has been secured, and grading is completed, having been done by the McArthur Bros. Co., of Chicago. The steel bridge work will be done by the Wisconsin Bridge & Iron Co., Milwaukee, Wis.; and the trestle work by Thomas Phee, of Chicago. Pres., Edward D. Adams, 35 Wall St., New York.

CLEARFIELD SOUTHERN.—This company was incorporated in Pennsylvania, July 6, with a capital stock of $30,000, to construct a steam railway from the mouth of Little Clearfield Creek to Belsena Mills, a distance of 15 miles. The incorporators are, Pres. A. W. Lee, W. B. Townsend, Samuel C. Stewart and Geo. H. Gearhart, all of Clearfield; David McGaughey, Osceola Mills, Pa.

COLOMBIA.—Press reports state that J. Ed. Buckley, 1906 Pacific Ave., Spokane, Wash., contemplates the construction of a narrow-gage railway from the head of navigation on the Magdelena River to Bucaramanga, a distance of about 90 miles. It is said that a 50-lb. rail will be used, and that the maximum cost of construction is estimated at $47,000 a mile. The government has given Mr. Buckley a concession for building the line, with a grant of 150,000 acres of land.

COLUMBIA SOUTHERN.—An extension of this line from Wasco to Klondike, five miles, has recently been completed, and work is in progress on the further construction of the line to Moro, Ore., making a total of 17 miles of new road. Track is expected to be laid to Moro by October 1. Pres., E. E. Lytle; Ch. Engr., E. E. Cooper, both of Wasco, Ore.

DELAWARE.—This company was incorporated in New York July 6 with a capital stock of $200,000, to construct and operate a steam railway from Delhi to Andes and Bovina Center, Delaware county, on the New York, Ontario & Western Ry., a distance of 15 miles. The directors are Herbert Sewell, of Walton, N. Y.; T. E. Hastings and Alexander Wilson, of Bovina Center; James F. Copp and W.C. Oliver, of Andes; S. P. Wilbur, Henry Honeywell, Henry Davies and G. W. Youmans, of Delhi, N. Y.

DULUTH & IRON RANGE.—Grading has been completed on the extension of this line from Waldo, Minn., to the Cloquet River; the laying of five miles of additional spur track is projected. J. L. Greatsinger, Pres. and Gen. Mgr., Duluth, Minn.

EASTERN CAROLINA.—This company has been incorporated in North Carolina, with a capital stock of $100,000, to construct and operate a railway from Tarboro to Crisp, N. C. Among the directors are B. F. Finney, Savannah, Ga.; Jefferson Cobb and Edward Pennington, Tarboro, N. C.

MEXICO.—Reports state that the Mexican government has executed a contract with Sir Weltman Pearson for the construction of harbors at Coatzacoalcos and Salina Cruz, and for the lease of the National Interoceanic Ry., Isthmus of Tehuantepec, which connects these two ports. The main object of these works, which will cost about $7,500,000, is to create a new interoceanic route, which, it is expected, will almost entirely supersede that of the Isthmus of Panama.

MINNEAPOLIS, ST. PAUL & SAULT STE. MARIE.—Thomas Greene, Acting Ch. Engr., Minneapolis, Minn., informs us that this company is at present engaged in grading its extension from Kulm, in La Moure county, to section 9 in the northern part of McIntosh county, N. Dak., where a junction will be formed with the old grade of the Aberdeen, Bismarck & North Western Ry., which was built in 1887 from Aberdeen, S. Dak., to Bismarck, N. Dak., but not ironed; it is now the property of this company. It is also intended to relay about 80 miles of the eastern division in Wisconsin and Michigan, between the station of Pennington and Gladstone, this summer with 72-lb. steel rails. The Kulm extension is to be completed in time to handle this year's harvest.

MINNESOTA, IOWA & GULF.—This company is said to have been incorporated at Des Moines, Ia., to construct a railway through Minnesota, Iowa and Missouri.

MISSISSIPPI, COLESBURG & MANCHESTER.—The Southwest Construction Co., of Kansas City, Mo., is said to have been awarded the contract for the construction of this new line of railway from Dyersville to Colesburg, via New Vienna and Petersburg, Ia. There will be no grade to exceed 1½% and no curves to be more than 4°; 60-lb. steel rails are expected to be used. Secy., W. C. Kirchheck, Colesburg, Ia.

MISSOURI & IOWA SOUTHERN.—J. E. House, Ch. Engr., Omaha, Neb., is said to be making the final survey for this proposed standard gage railway to be built from Sedalia to Miami, via Marshall, a distance of about 50 miles. It is expected to construct the line this year.

MISSOURI RIVER, ALBION & WESTERN.—This company was incorporated in Nebraska, July 12, with a capital stock of $100,000, to construct a line from the eastern boundary of the state at Decatur through Albion, and thence north and west to the South Dakota line.

NAVASOTA & MADISONVILLE.—R. J. Camp, Madisonville, Tex., informs us that the necessary subscriptions have been made for this proposed railway from Keith to Madisonville, via Bedias, Tex., 45 miles. It is now desired that some one will stock and operate the line, or take enough bonds to pay for the construction. This company proposes to build the road bed and lay the ties if the subsequent laying of rails and operation over the route is assured. Pres., J. E. Morris, Madisonville; Ch. Engr., B. F. Goodrich, Houston, Tex.

REIDSVILLE & DORCHESTER.—This company has been organized in Georgia, with a proposed capital stock of $100,000, to construct a railway from Dorchester to Greenville and Reidsville, Ga. Among those interested are George W. Perkins and T. W. Hardwick, of Tennille, Ga.; Henry C. Perkins, Augusta, Ga.; William Rawlings and R. L. Warthen, of Sandersville, Ga., and others. G. W. Perkins, of Tennille, informs us that preliminary surveys have been made over the route, 45 miles, and that the right of way has been donated wherever there is a permanent location. The entire capital has not yet been secured, but it is expected to let contracts as soon as the line is permanently located.

RIO GRANDE WESTERN.—E. J. Yard, Ch. Engr., Salt Lake City, Utah, informs us that Deal Bros. & Mendenhall, of Springville, Utah, have the contract for the building of a spur eight miles long, leaving the main line at Mile Post 138.1. Grading is nearly completed. Pres., W. J. Palmer, 11 Broadway, New York.

ST. FRANCOIS VALLEY.—Louis B Houck, Pres., Cape Girardeau, Mo., informs us that the survey has been made, the right of way obtained and the capital secured for this proposed railway, ten miles in length, to the north of Campbell, Mo. The contract is held by Louis Houck, of Cape Girardeau, and he has already graded about one mile additional road and cleared the right of way. Seven miles of the line was previously built and was known as the "Ward Road." A. R. Ponder, Ch. Engr., Cape Girardeau.

TEXAS CITY TERMINAL.—D. H. Wilson, Supt., Texas City, Tex., informs us that the only improvements being undertaken by this company are the construction of one mile of new track at the Texas City yards, and one-half mile of new sidings.

UNION TERMINAL.—The Union Terminal Association has filed articles of incorporation with the county clerk at Newark, N. J., to have a capital stock of $5,000,000, with $1,000 paid in, to acquire and control the property of the Kansas City & Atlantic R. R. Co., of Missouri; the Terminal Improvement Co., of Kansas City, and the Missouri Agricultural Fair Grounds Association, of Galliton township, Mo. The incorporators named are Jesse R. Salmon and Cortlandt Parker, Jr., of Newark; William H. Lee, Greenwood, Mass.; Vernon O. Taylor, Providence, R. I.; Francis E. Dana, Summit, N. J.; Stephen Salisbury and Theodore C. Bates, Worcester, Mass. Address Cortlandt Parker, Jr., 765 Broad St., Newark, N. J.

WESTERN MARYLAND.—C. O. Vandevanter, Principal Assistant Engr., Baltimore, Md., informs us that the improvements which this company is now making includes the construction of a branch line from Hagerstown to a point near Altenwald, Pa., 5.30 miles, and known as the Hagerstown & State Line R. R.; and the Washington & Franklin branch in Pennsylvania, 9.07 miles in length; work is to be completed by Oct. 1. As stated in a former issue, the contract for the grading, masonry and ballasting is held by J. R. Serpell & Co., of Louisville, Ky. A 17-stall round house is also being erected at Hagerstown, eight stalls of which are to be used as a machine shop; this is under contract to be completed by Aug. 31.

STREET AND ELECTRIC RAILWAYS.

DEDHAM, MASS.—The selectmen have granted a franchise to the Roxbury & Roslindale St. Ry. Co. to lay tracks in this place from Tracy Square to Oakdale Square, one mile.

FRAMINGHAM, MASS.—The Framingham, Southboro & Marlboro St. Ry. Co. has been incorporated, with a capital stock of $120,000, to build an electric street railway from Worcester St. in this place to Marlboro, via Southboro, nine miles. The directors are: S. H. Howe, F. D. Newton, C. B. Sawin, J. R. Entwistle, W. B. Ferguson, C. E. Barnes and G. A. Butman.

NEW BEDFORD, MASS.—The New Bedford, Middleboro & Brocton St. Ry. Co. was granted a hearing by the board of public works, June 30, on its petition for a franchise to build its line in this city. No action was taken on the petition. Abbott P. Smith, Frederick C. Hinds and L. Le B. Holmes represented the company.

WICKFORD, R. I.—The Sea View Electric Ry. Co. is planning to extend its line, which has just been put in operation from Narragansett Pier to Saunderstown and Wickford, according to reports.

BROOKLYN, N. Y.—Frederick Uhlman, Receiver of the Brooklyn Elevated R. R., is reported to be at work upon plans for connecting the Flatbush Ave. line of the road with the Long Island R. R. by a loop, for the purpose of running through trains from City Hall, New York, across the Brooklyn Bridge to Jamaica, L. I.——The Brooklyn Heights R. R. Co. has begun work on changing the motive power of the Sea View Elevated R. R., running from Brighton Beach to West End, Coney Island, from steam to electricity, besides building several hundred feet of bulkhead and filling, at a total cost of about $20,000, according to report.

BUFFALO, N. Y.—The Buffalo Valley R. R. Co. has applied to the railroad commissioners for a charter to build a railway from Java to this city, according to report.——The Buffalo Ry. Co. has filed plans with the board of public works for enlarged conduits for its wires in Niagara and Pearl Sts.

NEW YORK, N. Y.—The Union Ry. of the Borough of the Bronx is expected to open its branch from Mt. Vernon to New Rochelle Aug. 1.

HADDONFIELD, N. J.—Vice-Chancellor Reed has filed an opinion denying the injunction asked for by citizens of this place to restrain the West Jersey Traction Co. from constructing an electric railway on Main St. E. A. Armstrong and D. J. Pancoast represented the company at the hearing.

ORANGE, N. J.—The Suburban Traction Co.'s property in the Oranges and Bloomfield was purchased at auction sale July 6 by the Orange & Passaic Valley Ry. Co., the incorporation of which was noted in our issue of June 23. Col. Chas. A. Sterling, Pres. of the National Storage Co., represented the latter railway company, which assumes $60,000 in first mortgage bonds and $150,000 bonds held by the Manhattan Trust Co., which it expects to pay in full. The line will be made standard gage and will be improved, and the Bloomfield end extended to Passaic, through Brookdale, with a branch from the latter place to Upper Montclair. Plans have also been filed with the Secretary of State for an extension to South Orange.

PLAINFIELD, N. J.—The common council has refused to grant a franchise to the Plainfield St. Ry. Co. to operate a line on East 2d St. Adrian Riker, Secy. and Treas.

ALLENTOWN, PA.—Work has been begun on the extension of the Allentown & Kutztown Electric Ry., 18 miles long. An extension from this place to Emaus, six miles, is also under construction. It is also said that a line is projected through the cement regions of Lehigh county.

GREENSBURG, PA.—The Greensburg, Jeanette & Pittsburg Electric St. Ry. Co., running from this place to Manor, has been sold to a syndicate of Harrisburg capitalists, of which Benj. Myers and Patrick Russ are the principal members. The company proposes to improve the line and to extend it to Irwin. It will also purchase, according to report, the Greensburg & Hempstead Electric St. Ry., changing it to standard gage and extending it to Mount Pleasant. Supt., C. L. Brinser, Harrisburg, Pa.

HARRISBURG, PA.—The officers of the Cumberland Valley R. R. Co. have purchased a controlling interest in the Harrisburg & Mechanicsburg Electric Ry. Co., and will complete the line from New Cumberland to this city, according to report. Spencer C. Gilbert, Pres.

NEWTOWN, PA.—The Newtown Electric St. Ry. Co. is reported to be making surveys for an extension of its line from this place to Doylestown. There will be a number of overhead crossings of turnpikes and railways and a new bridge will have to be built over Mill Creek. Thos. P. Chambers, Pres.

PHILADELPHIA, PA.—The select and common councils have granted permission to the Union Traction Co. to remove one of its tracks on East Susquehanna Ave. and to lay in its stead a track on East Norris St., from Girard Ave. to East Thompson St., and also to reconstruct its line on Wayne Ave., Germantown. Permission has also been granted by the councils to the same company to extend its tracks and overhead system on Hunting Park Ave. from its present terminus to Old York Road, amending an ordinance of Feb. 25. Geo. D. Widener, Pres.

PORT CARBON, PA.—The Port Carbon & Middleport Electric Ry. Co. has been incorporated, with $100,000 capital, to build an electric street railway from this city to Middleport, seven miles. John A. Pattee, Pres.; R. S. Martin, Claude S. Jarvis, John D. Rishel and Henry E. Thale are the incorporators, all of Philadelphia.

WILMINGTON, DEL.—The street and sewer department has granted franchises to the Wilmington City Ry. to build new lines on Walnut St., from Front St. to East 8th St., and to build a line on Vandever Ave., from Claymont to Market St.——The Wilmington & Chester Traction Co. is now building its line between these cities. Pres., Clarence M. Clark.

WASHINGTON, D. C.—The Washington & University R. R. Co. has been incorporated to build a street railway in this city.

PETERSBURG, VA.—The Piedmont Traction Co. has asked for a franhcise to build an electric street railway in this city, six miles in length. T. O. Troy, Pres.

BIRMINGHAM, ALA.—The Birmingham Traction Co. is reported to have been granted a franchise to build its electric railway system in this city.

AKRON, O.—The Cleveland & Eastern R. R. Co. is about to apply to the county commissioners for a franchise to extend its line to this city, according to report.

SPRINGFIELD, O.—The Springfield Ry. Co. is considering the building of an extension to its electric railway from this city to Yellow Springs, according to report. S. L. Nelson, Mgr.

TOLEDO, O.—Dr. Smith, of Adrian, Mich., is reported to be interested in building an electric railway from Lyons to this city, via Sylvania, 28 miles.

BERRIEN SPRINGS, MICH.—The village council is reported to have granted a franchise to a party of South Bend, Ind., capitalists, to build an electric line from the latter city to Benton Harbor, via Berrien Springs.

DETROIT, MICH.—The Grand River Electric R. R. has begun operation between this city and Sand Hill. Seymour Brownell, Consult. Engr.

GRAND RAPIDS, MICH.—It is reported that the Grand Rapids & Lake Michigan Electric R. R. Co. will apply to the common council for a franchise to build its line from this city to Grand Rapids, 35 miles. The company has $500,000 capital stock, and the promoters are: Alex. E. Riopelle and Robert Hanneman, of Detroit, Mich.; Wm. J. Hess, Grand Rapids.

LANSING, MICH.—Surveys are being made for the Lansing, Dexter & Ann Arbor Electric Ry. Secy. Taylor may be addressed.

MOUNT CLEMENS, MICH.—The city council has granted a franchise to the Rapid Ry. Co. to lay tracks in this city, and to the Detroit, Lake Shore & Mount Clemens Ry. Co. to extend its tracks on East St. to Avery Square, according to reports.

EDWARDSVILLE, ILL.—The Mississippi Valley R. R. Co. has been incorporated to build an electric railway from St. Louis to Alton, through this city. The officers are: C. E. Carroll, Pres., St. Louis, Mo.; J. A. Mehling, Vice-Pres., Cleveland, O.; A. Holthaus, Secy. and Treas., St Louis, Mo.

HOWARD, ILL.—The common council has granted an extension of the franchise for the proposed electric railway to Geneva Lake until Sept. 1, 1899, the town board of Walworth having extended it until the same date. H. T. Windsor, Chicago, may be addressed for particulars.

OREGON, ILL.—The entire issue of $500,000 bonds for the Rock River Electric Ry. is reported to have been taken by Hirsch Bros, New York, and the Western Trust Co., Chicago. Construction will begin as soon as contracts have been let and the necessary water power, which is located at this place, has been purchased. Pres., E. M. Hopkins, Chicago.

DULUTH, MINN.—Luther Mendenhall, President of the Duluth St. Ry. Co., has been appointed its receiver, on application of Thomas Lowry, Minneapolis, who holds a judgment for $1,988 against the company.

WINONA, MINN.—The Winona Ry. & Light Co. has asked permission of the city council to relay its tracks at the east end of the city through a better residential district.

HAVELOCK, NEB.—The council has decided to submit the proposition on permitting the Lincoln Traction Co. to extend its lines to this city, to the vote of the people, according to report. Supt. Humpe may be addressed.

KANSAS CITY, MO.—The Central Electric Ry. Co. has been incorporated with $1,000,000 capital, to build and operate street railways in this and adjoining cities, to be operated by electricity, cable or other motive power. The incorporators are Wm. M. Reid, E. S. Yeomans, E. G. Vaughan, Frank S. Groves and Wm. C. Scarritt, of this city; S. M. Jarvis and Roland R. Conklin, New York. The company will begin construction of lines running from Kansas City, Kan.; Argentine, Armourdale, Westport, Washington Park and Fairmount Park, using the underground Budapest system, for which three large power houses will be constructed.——The Metropolitan St. Ry. Co. will commence immediately the construction of the Broadway electric line from 6th and Delaware Sts. to 17th St. and Madison Ave. Engineer, E. Butts.

ST. LOUIS, MO.—The St. Louis & Belleville Electric Ry. Co. has filed a mortgage for $500,000 with the Mississippi Valley Trust Co. of this city to secure bonds which will be used to complete the construction and equipment of its road, according to report.

OAKDALE, CAL.—The Oakdale Transit Co. has applied for a franchise to build an extension to its lines on 12th St., from Broadway to Oak St., and thence to 11th St.

SAN BERNARDINO, CAL.—J. H. Boyd is reported to be interested in the construction of an electric railway from this city to Redlands.

ELECTRIC LIGHT AND POWER.

DEERING, ME.—The Deering Electric Light Co. has been awarded the contract for furnishing 273 25-c. p. incandescent lights for one, three or five years, beginning Oct. 1.

WATERBURY, VT.—W. P. Dillingham, of Waterbury; Mr. Briggs, of Brandon, Vt., and three engineers, have made surveys and a report for the National Life Insurance Co. of the proposed plant at Bolton Falls for the Bolton Falls Power Co. The insurance company, it is stated, has been asked to advance money for the construction; estimated cost, $75,000.

CONCORD, MASS.—Bids are asked until Aug. 1 for furnishing and installing two boilers, a feed pump, condenser, two heaters, etc., for the electric light plant, as stated in our advertising columns. Engrs., Stone & Webster, 4 Post Office Square, Boston, Mass.; Chn. Com., R. F. Barrett.——A press report states that at a town meeting July 9 it was voted to appropriate an additional $15,000 to the $35,000 already appropriated for the plant. The additional sum is required for placing 3½ miles of wire under ground.

GLOUCESTER, MASS.—Frank E. Davis, Mayor, writes us that nothing will be done this year in regard to the proposed plant.

MANSFIELD, MASS.—Chas. C. Hagerty, Clk., writes us that it is not likely that the water supply district will vote to accept the act authorizing it to establish a plant for electric lighting.

WOBURN, MASS.—The Woburn Light, Heat & Power Co. has let the contract for furnishing three 400-HP. direct-connected, cross-compound condensing engines for its plant to the Blake Engine Co., Warren, Mass. The company, it is stated, will let other contracts this week.

BUFFALO, N. Y.—Preparations are being made to erect a terminal station for the Cataract Power & Conduit Co., it to be located a short distance north of the Bullymore malthouse, in Niagara St. The new malthouse in course of construction by the Curtiss estate will probably use power distributed from the new terminal station. Consult. and Des. Engrs., Hand & Greenburg and Carlton & Meadows, Buffalo; Gen. Mgr., Chas. R. Huntley.

COXSACKIE, N. Y.—A. E. Rowell, Village Pres., writes us that the contract for furnishing and constructing the proposed plant is probably already let. The poles are now being delivered. The plant will be owned by the J. G. Newbury Co.

SPENCER, N. Y.—T. C. Washburn, Village Pres., writes us that all contracts for furnishing and building the plant to be owned by S. A. Seely have been let. The plant will have a capacity for one or two arc and 40 32-c. p. incandescent lights. Des. Engr., Maurice Moon.

SYRACUSE, N. Y.—The question of erecting ornamental electric light poles on Salina and certain other streets is being considered, according to local papers.

WHITESBORO, N. Y.—Bids are asked until Aug. 20 for lighting this village with about 30 2,000-c.p. arc lights for a term of five or more years, as stated in our advertising columns. Engr., W. G. Stone, Utica, N. Y.; Clk., G. A. Kirkland.

JERSEY CITY, N. J.—The People's Light & Power Co. is erecting a new boiler house in connection with its electric plant. It is 60 ft. wide and about 90 ft. long, contains space for large upright boilers, and has an arrangement for the storage of coal in the steel bunker inside the building, so that the fuel can be easily taken direct to the boilers. The tracks are arranged so that railway cars will run into the building, and discharge the coal directly into the bunker. It is of fireproof construction throughout, with steel frame, brick side walls, and iron roof covering, well lighted and ventilated. The steel work is being furnished and erected by the Berlin Iron Bridge Co., of East Berlin, Conn. Sandford & Stillman, of Jersey City, have the contract for the building.

PHILADELPHIA, PA.—The D'Olier Electric Co., 129 South 11th St., Philadelphia, has been awarded the contract at $9,319 for furnishing and placing the tubing, electric wires, etc., in the new Central high school building. The contract for the plant was let July 11 to Walker & Kepler, 531 Chestnut St., at $26,780.

WILLIAMSPORT, PA.—The city clerk writes us that nothing new has developed in regard to putting in a plant.

WASHINGTON, D. C.—Bids are asked by the district commissioners until July 30 for lighting the streets with incandescent and electric arc lights for the year ending June 30, 1899, as stated in our advertising columns.

WILLIAMSPORT, MD.—M. Emmett Cullen, Town Treas., writes us that the burgess named one set of supervisors to execute the act authorizing the town to erect a plant and issue $20,000 in bonds for the same. The supervisors were not confirmed, and the burgess has so far failed to nominate others or say when he intends to do so.

DARLINGTON, N. C.—The Charlotte Electrical Engineering & Supply Co., Charlotte, N. C., has been awarded the contract for furnishing and putting in a plant for the Darlington Mfg. Co.

LAFAYETTE, ALA.—We are informed that bids are wanted by the city at any time for furnishing and constructing a plant. It will have a capacity for 25 2,000-c. p. arc and 800 incandescent lights; estimated cost, $10,000. Charles Schurssler may be addressed.

UNION SPRINGS, ALA.—P. L. Cowan, Clk., writes us that we made a mistake in our issue of June 30 in stating that the city had not sold $20,000 in bonds for the proposed plant. The town issued $10,000 in bonds several months ago, and were sold the latter part of May to D. M. Farsen, Chicago. Mayor, A. D. Fielder.

OPELOUSAS, LA.—Bids are asked until July 15 for leasing the plant and water-works about constructed. The lessor is to supply the city with 40 arc and four incandescent lights free of charge. Thos. H. Lewis, Jr., Cy. Clk

COVINGTON, KY.—The aldermen are considering the question of authorizing the city clerk to ask for bids at once for lighting that portion of the city which is not lighted with gasoline. Bids will be wanted for electric, gas and gasoline lighting. The present contract for the gasoline lighting expires in September.

TOLEDO, O.—H. E. Marion writes us that the Toledo Heating & Lighting Co., just incorporated, is the successor to the Home Heating & Lighting Co. The old plant will be operated for the present, and it is not probable that a new plant will be erected this season. Gen. Mgr., H. J. Yaryan.

BELLAIRE, MICH.—C. S. Guile, Pres., writes us that the town is not yet ready to take action with regard to putting in a plant.

CASS CITY, MICH.—Bids are asked until July 22 for furnishing and constructing a plant and water-works. Engr., Geo. C. Morgan, 808 Royal Insurance Bldg., Chicago, Ill.; H. W. Seed.

DECATUR, MICH.—E. J. Rawson, Clk., writes us that bids will be wanted the latter part of July for furnishing and constructing a plant to cost $6,000. Plans have not yet been prepared.

HOLLAND, MICH.—It is reported that this place will extend the plant, at a cost of about $3,361. Supt., F. W. Fairfield.

SAULT STE. MARIE, MICH.—Local papers state that Mason, Hoge & Co., Chicago, Ill., and Erskine D. Smith & Co., Philadelphia, Pa., submitted the lowest bids July 1 for constructing the power canal for the American Lake Superior Water Power Co., advertised in Engineering News. The bids on the intake are said to have ranged from $75,000 to $350,000. The entire work will cost from $1,275,000 to $2,000,000. The canal is to be completed by Jan. 1, 1900. Ch. Engr., H. von'Schon, Sault Ste. Marie.

BELOIT, WIS.—The Beloit Electric Light & Power Co. has purchased the old Rock River Paper Mill property, and will change the property into an electric light and power plant. The purchase carries with it a valuable water power. The electric company will spend $25,000 in improvements, according to reports. G. L. Cole, Vice-Pres. and Purchasing Agent.

SUPERIOR, WIS.—It is stated that the Great Northern elevators are to be equipped with electricity instead of steam. Ground has already been broken for the engine house, to be 84 × 64, and for the boiler house, to be 77 × 44 ft.

DULUTH, MINN.—Press reports state that the council light committee will probably have a proposition for submission in regard to the question of electric lights. The contract under which the lighting is now done expired last month, but lights are being continued under it. It is probable that the $50,000 paid yearly for lights will be cut in two by the committee and that naphtha lamps will be used in the suburbs, instead of arc lights as now. The city will make a contract for what electric lights it will be willing to take for one year, and before its expiration will have decided what it wants to do, and construct its own plant. Several other systems of lighting other than electricity are being considered, but whatever system is put in the municipality will be in control and ownership.

NEW PAYNESVILLE, MINN.—Bids are asked until July 15 for furnishing and constructing the proposed plant and water-works, according to reports. Engrs., Fairbanks, Morse & Co., St. Paul, Minn.

TOPEKA, KAN.—The executive council is considering the question of putting in a plant at the state house.

WATER-WORKS.

DANFORTH, ME.—We are informed that this place will not build works this season, as has been reported.

DEXTER, ME.—This town has taken no action on the matter of water-works, and the intention at present is to abandon the idea. The town has a partial fire service, and several private pipe lines from the springs are owned by individuals. Engr., P. H. Coombs, Bangor, Me.

ENFIELD, MASS.—H. M. Smith writes us that no work will be done on the proposed new works or in enlarging the present reservoir this season. No money has been appropriated by the town for works.

HUNTINGTON, MASS.—Bids are asked by the commissioners until July 27 for building a dam, laying about four miles of water pipe, etc., for the proposed works. There will be required 700 cu. yds. of rubble masonry and 1,200 yds. of earth filling. Engrs., E. C. & E. E. Davis, Northampton, Mass.

WATERTOWN, MASS.—Dr. Bennett F. Davenport, Chn. Com., writes us that the Watertown Water Supply Co. having rejected the offer made by the committee to accept in payment for its works, which the town had taken, the sum of $400,000, the case is being prepared for trial before the commissioners.

ALBANY, N. Y.—Bids are asked until Aug. 2 for furnishing and constructing a pumping station at the new filtration plant. Geo. I. Bailey, Supt.

OSWEGO, N. Y.—It is proposed to extend the water mains in several streets.

ALDEN, N. Y.—The people are considering the question of holding another election to vote on the proposition to issue bonds for works. It was reported last year that J. F. Witmer, 705 Ellicott Sq., Buffalo, had prepared plans.

WEST TROY, N. Y.—The water commissioners of Watervliet are considering the question of building new works. The water supply would be secured from the Tomhannock Creek, a short distance east of Troy. Estimated cost, about $200,000. Consult. Engr., Elnathan Sweet, 13 Tenbroeck St., Albany.

ASBURY PARK, N. J.—The township committee has granted a franchise to the Ocean Grove Association to supply water to West Grove and Bradley Park. Township Clk., Jos. Harris.

JERSEY CITY, N. J.—Bids are asked by the street and water board until Aug. 18 for furnishing this city with a water supply. The new specifications call for a 50,000,000 gallon supply with the option of increasing the supply to 70,000,000 gallons. Two pipe lines will be constructed, one of a 50,000,000 gallon capacity, and the other capable of carrying a 30,000,000 gallon supply.

NEWARK, N. J.—Press reports state as follows: Engineers have selected a site for a 700,000,000-gallon storage reservoir half a mile south of Great Notch, back of the Orange Mountain range and in a natural basin quite near the conduits which supply the city from the Pequannock watershed. The report states that this action was caused by the warning from the East Jersey Water Co. that the city was using more than 2,700,000 gallons daily, which is the quantity fixed by the contract until the city makes its final payment for the works in 1900.

BEAVER, PA.—Bids are asked until July 18 for furnishing and laying about 5,000 ft. of 10-in. cast-iron water pipe, sinking a pump well and erecting a pumping station, furnishing two triplex power pumps of 500,000 gallons each, and two gas engines, and for constructing a 1,000,000-gallon reservoir, etc. Engr., J. P. Leaf, Brighton St., Rochester, Pa.; Jno. Aiken, Chn. Com.

BOYERTOWN, PA.—The council has issued $35,000 in bonds for the proposed works. J. K. Grant, Borough Solicitor.

CHARLESTON, ILL.—Bids are asked until July 15 for about 6,000 sq. yds. of brick paving. T. V. Miles, Cy. Clk.

PROVISO, ILL.—Bids are asked until Aug. 1 for constructing four miles of macadam road. R. E. Williams, Engr., 84 La Salle St., Chicago; Jacob Bohlander, Town Clk., Maywood.

KEWANEE, ILL.—Bids are asked until Aug. 1 for paving Tremont St.; appropriation, $45,000. J. C. Quade, Cy. Engr. ——The council has appropriated $20,000 for sidewalks, etc.

MILWAUKEE, WIS.—Bids are asked until July 15 for the purchase of $140,000 of street improvement bonds. Wm. J. Fiebrantz, Comptroller.

OSHKOSH, WIS.—The council is considering a proposition to spend $40,000 for macadamizing in seven streets. A. B. Ideson, Mayor.

DES MOINES, IA.—Bids are asked until July 20 for cement curb and brick paving on Pleasant St. E. W. Woodruff, Cy. Clk.

MUSCATINE, IA.—The council has awarded contracts for brick paving in District No. 14, to Edwards & Walsh, at $10,496, and in District No. 15, to Fuller Bros., at $8,618.

DULUTH, MINN.—Bids are asked until July 22 for improving Fifth St., between 26th Ave. and 27th Ave. R. Murchison, Clk. Bd. Pub. Wks.

MINNEAPOLIS, MINN.—Bids are asked until July 29 for furnishing artificial combined curb and gutter, to be used during the season of 1898; surety, $200. F. W. Cappelen, Cy. Engr.; L. A. Lydiard, Cy. Clk.

ST. PAUL, MINN.—Bids are asked until July 18 for grading the extension of Cleveland Ave. D. M. Sullivan, County Audr.

INDEPENDENCE, KAN.—We are informed that bids are asked until July 31 for 23,000 sq. yds. of brick paving, requiring 7,000 cu. yds. of excavation. John M. Walker, Cy. Engr.

TOPEKA, KAN.—The Gilsonite Paving & Roofing Co., St. Louis, Mo., has been awarded a contract, by the council, at $10,291 for paving the driveways, walks, etc., in the state house square.

SHERMAN, TEX.—Tom Randolph writes us that the council is considering a proposition for certain paving. It is not yet ready to ask for bids for the work. Councilmen C. P. Gregory, M. H. Andrews and R. R. Dulin may be addressed.

OAKLAND, CAL.—Bids are soon to be asked for macadamizing three county roads.

MANUFACTURING PLANTS.

BUFFALO, N. Y.—It is said that the plant of the Buffalo Co-operative Brewery will be rebuilt at a cost of $25,000.—— G. Fred Zellers Sons will build an addition to their tannery to cost $10,000.

ROCHESTER, N. Y.—Plans have been prepared for a 6-story brick and stone factory building, 285 × 75 ft., to be erected here for the Utz & Dunn Shoe Mfg. Co.; reported cost, $10,000. Archs., Ellis & Ellis, Powers Bldg., Rochester.

JERSEY CITY, N. J.—A new silk factory will probably be erected in this city for C. Stohn's Sons, Summit Ave. and Bleecker St.; estimated cost, $20,000. Arch., Emil Guhl, 19 Charles St., Jersey City.

PHILLIPSBURG, PA.—H. L. Forte & Co., Drexel Bldg., Philadelphia, Pa., have been awarded the contract for the erection of six additional buildings to the plant of the Vulcanite Portland Cement Co., at Vulcanite Station, on the New Jersey Central R. R., near Phillipsburg. Two of the buildings are 2-story and four 1-story, the largest measuring 600 × 80 ft.; estimated cost, $100,000. Archs., Hales & Ballinger, 11th and Chestnut Sts., Philadelphia, will supervise the work, which will be started at once.

PHILADELPHIA, PA.—The 5-story brick factory building of Halton & Shoemaker, at Boone and Diamond Sts., was destroyed by fire July 10, causing a loss of about $100,000; fully insured.

YORK, PA.—The York Mfg. Co., of York, informs us that it will erect a new 2-story addition to its plant, 130 × 80 ft., to be built of slow burning material. The power equipment will be furnished by the company.

NATIONAL SOLDIERS' HOME, VA.—The Hendrick Mfg. Co., Carbondale, Pa., has been awarded the contract for building the extension of the Pontifex ice machine plant at the southern branch of the National Home for Disabled Soldiers, at this place, at $4,990.

EAST DURHAM, N. C.—It is reported that the Durham Cotton Mfg. Co., of East Durham, will build an addition, 125 × 250 ft., requiring the installation of 5,400 additional spindles and 160 looms.

CEDARTOWN, GA.—A. F. Walker, 517 Austin Bldg., Atlanta, Ga., informs us that work has just commenced on the construction of the Paragon Mills in Cedartown. This plant will manufacture hosiery yarns, and will have a present equipment of 10,640 spindles.

COVINGTON, GA.—A 3-story addition, 300 × 80 ft., will be erected for the Porterdale Mills at Covington, and with other improvements, including 15,000 spindles, will cost about $150,000. Pres., J. F. Hanson, of Atlanta, Ga.

CROWLEY, LA.—It is reported that a rice mill will be built at this place, consisting of a 4-story building, 40 × 40 ft., and a 2-story warehouse, 100 × 150 ft. Contracts for construction and machinery are said to have been let. Pres., J. D. Crowley.

LOUISVILLE, KY.—The plant of the Globe Refining Co., situated on the outskirts of the city, was entirely destroyed by fire July 3, entailing a loss of $200,000; insurance, about $135,000. Secy., C. J. Hewitt.

PORTSMOUTH, O.—B. F. Vincent, Secy. and Treas., Burgess Steel & Iron Works, of Portsmouth, informs us that nothing definite has yet been done towards the erection of the proposed addition to the company's plant, but that a location will probably be decided upon within 30 days and the erection of the plant be begun.

LAWRENCEBURG, IND.—A fire in this city July 4 destroyed property valued at $100,000, including the Walsh distillery, cattle pens and the Oaster pens.

HAMMOND, IND.—The Western Starch Manufacturers' Association's plant at West Hammond was damaged by fire July 10, causing a reported loss of $250,000.

HOQUIAM, WASH.—Reports state that the F. K. Wood Lumber Co. will soon erect a complete dry kiln, 140 × 104 ft., at this place. H. J. Starr, Supt. of Construction.

MISCELLANEOUS CONTRACTS.

DREDGING.—Petaluma, Cal.—N. S. Frost, Cy. Engr., writes us that he is making surveys for 6,000 lin. ft. of tidal river for dredging.

RETAINING WALL.—Cincinnati, O.—Bids are asked until July 25 for building a retaining wall. A. P. Butterfield, Clk. Bd. City Affairs.

DREDGING.—Lorain, O.—Bids are asked until Aug. 2 for dredging Black River, as stated in our advertising columns. G. A. Resek, Cy. Clk.

DOCK.—Albany, N. Y.—F. A. Harrington, Pier Supt., has been directed to apply to the council for an appropriation to construct from 800 to 1,000 ft. of new dock.

EMBANKMENT, ETC.—Shelton, Wash.—Bids are asked until July 23 for strengthening the banks of Goldsboro Creek; estimated cost, $1,000. W. S. Covill, Town Clk.

PIERS.—Cleveland, O.—Bids are asked until Aug. 5 for constructing pile and timber piers, with stone filling at Erie St. and at Seneca St.; surety, $5,000. Geo. R. Warden, Dir.

IRON FENCE.—Pittsburg, Pa.—Bids are asked until July 18 for furnishing and erecting 400 ft. of iron fence at the Pittsburg City Home, at Marshalsea. Geo. Booth, Dir. Dept. Charities, 511 Fourth Ave.

TELEPHONE LINE.—Portland, Ore.—Reports state that the Columbia Telephone Co. is arranging to construct a line from this city to Washougal, Wash. General Manager Lamont, Portland, may be addressed.

DITCH.—Harvel, Ill.—Bids are asked until July 25 for constructing about 11 miles of drainage ditch. There will be required about 60,000 cu. yds. of earth excavation; bond, $1,000. Fred. Bertman, Chn. Drainage Comrs. of Bug River District.

LIGHTHOUSE SUPPLIES.—Tompkinsville, N. Y.—Bids are asked until July 25 for furnishing miscellaneous articles for the lighthouse establishment for the year ending June 30, 1899, as stated in our advertising columns. Lieut.-Col. D. P. Heap, U. S. Engr.

TELEPHONE WIRES, ETC.—St. Louis, Mo.—The general appropriation bill will include an item for $53,000 to purchase new wires for telephone, etc., to be placed underground, according to reports. Robt. E. McMath, Pres. Bd. Pub. Improvements.

TELEPHONE EXCHANGES.—New Orleans, La.—Reports state that a contract has been awarded to the Detroit Telephone, Switchboard & Construction Co., Detroit, for installing a 5,000-telephone exchange. Work will commence by Sept. 1. Manager Ahren may be addressed.

FIRE ENGINES, REPAIRS, ETC.—New York, N. Y.—Bids are asked by the fire department, 157 East 67th St., until July 27, for furnishing three fourth-size steam engines, having La France, New American and Amoskeag pumps and boilers, respectively; also for repairing four fourth-size Clapp & Jones fire engines. John J. Scannell, Fire Comr.

CHANNEL WORK.—Barnstable, Mass.—Frederick N. Wales, Clk., State House, Boston, informs us that the following bids were received July 7 for constructing oak pile jetties and excavating a channel through Dead Neck Beach, advertised in Engineering News June 30: Geo. H. Cavanagh, 166 Devonshire St., Boston, $13,690; Benj. Young, 17 Otis St., Boston, $20,980; R. G. & J. S. Packard, 130 Pearl St., New York, N. Y., $22,115.

SHIP CANAL.—Japan.—Press reports state as follows: Japanese government officials are at present discussing a scheme for constructing a ship canal from Osaka Bay on the Pacific to Isuruga on the Japan Sea, by way of Lake Biwa. Lake Biwa's present surface is 279 ft. above sea level and will supply 46% of the distance to be covered. As the lake is 262 ft. deep it is calculated that it can be lowered 135 ft., thereby producing a large area of dry land on its shores. It it estimated that the work can be completed in 10 to 15 years, at an expense to the government of $7,000,000 to $10,000,000 a year.

FLOATING DOCKS.—Washington, D. C.—Press reports of July 12 state as follows: The navy department is asking for bids for two floating docks, the two to cost not more than $250,000. M. T. Endicott, Chief Bureau of Yards and Docks, has been anxious to get some of these floating structures in order to send them to the Gulf and possibly to Cuba, where cruisers, gunboats and auxiliary craft could be docked in them, obviating the necessity of sending the ships to Northern docks. There are a number of floating docks in view, and it is expected that two of these will be secured under the bids asked July 12, without waiting the long time necessary to build such structures. Two such docks are at New York and three more are in and about New Orleans. An officer of the Bureau is now in New Orleans looking over the docks, in anticipation of their being offered to the government. The choice will be made with little delay. The bids for the floating docks to be built at New Orleans will be called for in about ten days.

CONTRACT PRICES.

STAND-PIPE.—Seattle, Wash.—Frank Olesen, Secy. Bd. Pub. Wks., informs us that the following bids were received June 30 for furnishing the material and for constructing a stand-pipe for the Cedar River water supply; the contract for the foundation has been let to T. Ryan, at $5,340:

Bids Received at Seattle, Wash., June 30, 1898, for Material and Constructing a Stand-pipe.

Quantities.		Moran Bros. Co., Seattle, Wash.	Wolfe & Zwiker Iron Wks., Portland, Ore.	Nelson & Phelps, 115 Dearborn St., Chicago.	Gillette-Herzog Mfg. Co., Minneapolis, Minn.	Chicago Bridge & Iron Co., Chicago, Ill.	Great Western Boiler Works, Seattle, Wash.

TELFORD-MACADAM PAVING.—Quincy, Ill. — Local papers state that the following bids were received June 24, 1898, for paving 17 blocks of the Boulevard, from Broadway to Harrison St., with telford-macadam: Fred Kordsiemon, grading, 14 cts. a cu. yd.; telford paving, 37½ cts. a sq. yd.; Ebert & Shannahan, grading 15 cts. a cu. yd.; telford paving, 44 cts. a sq. yd.; Zengle Bros., grading, 20 cts. a cu. yd.; telford paving, 45 cts. a sq. yd. The lowest bid aggregated $6,612 for a roadway 16 ft. wide for the 17 blocks, and $5,881 for a 14-ft. roadway. The Park and Boulevard Association has $4,360 for the work—$1,000 appropriated by the city, $1,000 by the county, $300 by Melrose, and the balance contributed by private subscriptions.

GUN CARRIAGES.—Washington, D. C.—It is stated that the following bids were received June 3, 1898, by the chief of ordnance for furnishing 18 12-in. and 6 8-in. disappearing gun carriages: 8-in.—Builders' Iron Foundry, Providence, R. I., 6 carriages, $11,515 each; first in 6 months and one a month thereafter. Walker Co., Cleveland, O., 6 carriages, $10,000 each; first in 120 days, and one every 20 days thereafter. Weimer Machine Works Co., Lebanon, Pa., 4 carriages, $11,750 each; 6 carriages, $11,400 each; first in 6 months and for each additional carriage add 7 weeks. Dixon Mfg. Co., Scranton, Pa., 6 carriages, $12,750 each; first in 6 months, and one every 6 weeks. Morgan Engineering Co., Alliance, O., 6 carriages, $9,985 each; first in 5 months, and one every 30 days. Frazier & Chalmers, Chicago, Ill., 1 carriage, $14,265; 2, $12,850; 6, $11,500; first in 100 days, and one every 20 days. Pond Machine Tool Co., Plainfield, N. J., 6 carriages, $12,500 each, first on Oct. 1, 1898, and one every 3 weeks; or $12,000 each, first on Nov. 1, and one a month. Lake Erie Engineering Works, Buffalo, N. Y., 1 carriage, $11,500; 2, $11,250; 6, $10,650; first in 7 months, second in 9 months, third in 10 months, fourth in 12 months, and one per month thereafter.

12-in.—Lake Erie Engineering Works, 19 carriages, as follows: 3 to 5, $33,500; 6 to 10, $33,250; 11 to 15, $33,000; 16 to 19, $32,750; first in 5 months, second in 7 months, third in 9 months, fourth in 10½ months, fifth in 12 months, and one a month thereafter. Morgan Engineering Co., 5 carriages, $32,250 each; first in 6 months and one every 6 weeks until three are delivered, then one every 30 days. Wm. Cramp & Sons Ship & Engine Building Co., Philadelphia, 5 carriages, $33,950 each; first in 6 months and one every 2 months. Robert Poole & Sons Co., Baltimore, 5 carriages, $32,250 each; first in 6 months and one every 1½ months thereafter. Bethlehem Iron Co., South Bethlehem, Pa., 5 or more carriages, $32,250 each; first in 6 months, second and third in 9 months, and one a month. Builders' Iron Foundry, 5 carriages, $39,500 each; first in 8 months, and one every 10 weeks. Weimer Machine Works Co., 3 carriages, $35,500 each; 6, $35,000; more than 6, $34,350 each; first carriage in 7 months, and one every 9 weeks thereafter.

ASPHALT PAVING.—Atlanta, Ga.—J. D. Turner writes us that the Warren-Scharf Asphalt Paving Co., 1 Broadway, New York, was awarded the contract July 5, 1898, for paving Washington St., from Hunter St. to Woodward Ave., at $2.08 a sq. yd.; total, $17,082.

LEVEE WORK.—Memphis; Tenn.—We are informed that the following bids were received July 6 for levee construction in Arkansas; Capt. H. C. Newcomer, U. S. Engr., C. B. Duke, Ch. Clk., Equitable Bldg.:

Bids Received at Memphis, Tenn., July 6, 1898, for Levee Work on the Upper Tensas Levee.

Bidder.	Upper Tensas Levee District, —in Arkansas.					Upper Tensas, —in Louisiana.

INDUSTRIAL NOTES.

THE MARION STEAM SHOVEL CO., Marion, O., writes us that business has been very good, and that it has been very busy all the season.

THE THOMSON METER CO., Brooklyn, New York, sold from Jan. 1, 1898, to July 1, 1898, 11,496 meters, which was 2,595 more than it sold in the first six months of 1897. So far 116,678 meters in all have been sold.

G. M. BURKHALTER & CO., 708 South 23d St., Birmingham, Ala., has just received a $25,000-contract for paving streets at Meridian, Miss. The company is now constructing about two miles of sewers in the same city.

THE WEBER GAS & GASOLINE ENGINE CO., Kansas City, Mo., is reported to have received a contract from the British government for six cable hoisting machines to be used in British Guinea for raising telegraph cables. The machines will have a raising capacity of eight tons elevated 40 ft. a minute, and will cost about $20,000.

THE BETHLEHEM IRON CO., South Bethlehem, Pa., was the builder of the crank, line, thrust and propeller shafts and all other hollow forgings of the U. S. battleship "Oregon," whose performance in steaming from San Francisco, Cal., to Key West, Fla., without a break in her machinery, and reporting immediately upon her arrival for active service, has already been noted in this paper. To have been able to make this record, it was absolutely essential that all parts of the machinery should be of the best, thus showing, it is claimed, the durability of hollow forgings over solid forgings for such purposes. We are informed that all the above-named shafts had a 6-in. hole running through them.

A. B. BOWERS, San Francisco, Cal., has been granted an injunction by the United States Circuit Court of the Southern District of New York, restraining the New York Dredging Co. from infringement of the Bowers patents on hydraulic dredges, but allowing the completion of the latter's contract at League Island, Cal., and also the work at Port Arthur, Tex., on filing bonds for profits and damages. Those interested in the legal aspects of the Bowers hydraulic dredge patents litigation, will find decisions in his cases in 63 Fed. Rep., p. 572; 69 Fed. Rep., p. 640; 77 Fed. Rep., p. 980; 80 Fed. Rep., p. 121; 25 U. S. A., p. 323; 48 U. S. A., p. 120; 80 Fed. Rep., p. 119; 106 U. S. A., p. 720; 81 Fed. Rep., p. 569; 83 Fed. Rep., p. 944. There are some other decisions not yet published.

Contract Work Should Always be Advertised in a Paper Read by Contractors.

Nearly Every Prominent Contractor and Manufacturer of Contractors' Supplies in North America Reads Engineering News.

INDUSTRIAL NOTES 24

PERSONAL.

Mr. Edwin C. Baggs has been appointed Receiver of the Denver City Cable Co., Denver, Colo.

Mr. Harry T. Litchfield has been appointed Superintendent of the electric light plant at Lilly Dale, N. Y.

Mr. Paul Dato has been appointed Superintendent of the water-works at Hillsboro, Tex., to succeed Mr. O. J. Morris, resigned.

Mr. L. F. Bellinger, civil engineer, of Atlanta, Ga., has been commissioned Captain in the Third Regiment of U. S. Volunteer Engineers.

Gen. Thomas S. Mumford, of Baltimore, Md., has been elected President of the Chesapeake & Ohio Canal Co., to succeed Mr. Stephen Gambrill.

Messrs. Bartl & Smith, civil and mining engineers, have removed their offices from 507 Lackawanna Ave., to the Connell Bldg., Wyoming Ave., Scranton, Pa.

Mr. W. H. Gridley has been appointed Superintendent of the St. Louis, Peoria & Northern Ry., with headquarters at Springfield, Ill., to succeed Mr. L. S. Graves, resigned.

Mr. John W. Hill, M. Am. Soc. C. E., of Cincinnati, O., has been appointed expert for the city of Indianapolis, Ind., to determine the physical condition of the plant of the Indianapolis Water Co.

Mr. Charles H. Meyers, M. Am. Soc. C. E., has resigned his position as Engineer of Sewer Construction in the Borough of Brooklyn, and has resumed private practice at 45 Broadway, New York.

Mr. John F. Hayford, Assoc. M. Am. Soc. C. E., Ithaca, N. Y., has been appointed Expert Computer and Geodesist in the U. S. Coast and Geodetic Survey, and is charged with the duties of chief computer.

Mr. William C. Winter, Assistant, Claim Agent of the Chicago, St. Paul, Minneapolis & Omaha Ry., with headquarters in St. Paul, Minn., has been appointed an Assistant Superintendent of the Union Pacific R. R.

Mr. Eugene W. Stern, M. Am. Soc. C. E., for the past six years Engineer of the Koken Iron Works, St. Louis, Mo., has accepted the position of Chief Engineer of the Jackson Architectural Iron Works, New York city.

Mr. Almon B. Atwater, M. Am. Soc. C. E., Division Superintendent of the Western Division of the Grand Trunk Ry., with headquarters at Detroit, Mich., has been appointed Assistant General Superintendent of the Michigan Central R. R.

Mr. Stewart Brown, Vice-President and Manager of the National Surety Co., of New York city, has been elected President of the Erie & Central New York Ry., to succeed Mr. Wayland D. Tinsdale, resigned, with headquarters at Cortland, N. Y.

Mr. Howard Gould has been elected President of the Tubular Dispatch Co., New York city, to succeed Mr. John E. Milholland. This company controls the New York Mail & Transportation Co., which owns the pneumatic mail tube lines crossing the New York and Brooklyn Bridge.

Mr. George Chipman Martin, C. E., formerly a member of the staff of Engineering News, has been appointed a Second Lieutenant of Infantry in the regular army of the United States. Mr. Martin is a graduate of the Engineering Department of the University of Vermont, in the class of 1892.

Mr. J. Francis Le Baron, M. Am. Soc. C. E., of Jacksonville, Fla., has been appointed a Captain in the Tenth U. S. Volunteer Infantry, but has declined in order to go to Honduras, where he has been appointed Chief Engineer of the Improvement of the Patuca River and Bar, as noted in our last issue.

Mr. Hadley Baldwin, Supervisor of Track of the Cleveland, Cincinnati, Chicago & St. Louis Ry., with headquarters at Terre Haute, Ind., has been appointed Engineer of Maintenance of Way of the Chicago Division, with headquarters at Indianapolis, Ind., to succeed Mr. T. O. Morris.

Mr. David Molitor, M. Am. Soc. C. E., United States Assistant Engineer on River and Harbor Improvements, with offices in the Telephone Bldg., Detroit, Mich., will take charge of a precise level party which will run a duplicate line between Lake St. Francis and Cape Vincent, along the St. Lawrence River, Ontario, for the United States Deep Water-Ways Commission and the United States Lake Survey.

Maj. A. Macomb Miller, M. Am. Soc. C. E., Corps of Engineers, U. S. Army, with headquarters in New York city, has relieved Col. T. A. Bingham, temporarily in charge of the Washington Aqueduct. He will assume the work of completing the Lydecker tunnel and reservoir, authorized by a recent act of Congress.

Mr. William P. Richards, civil engineer, has been appointed Surveyor of the District of Columbia, to succeed Capt. Henry Brigham Looker, Assoc. M. Am. Soc. C. E., First District of Columbia Volunteers, who is at the front. Mr. Richards for the past seven years has had charge of the extension of streets in the district.

Mr. Alfred M. Quick, formerly an assistant in the City Engineer's Office, Providence, R. I., and to Mr. Samuel M. Gray, M. Am. Soc. C. E., of the same city, and recently Assistant Engineer of the Water Department, Baltimore, Md., has become associated as a member of the firm of Hill & Howard, consulting engineers, with offices in the Manufacturers' Record Bldg., Baltimore.

Mr. William Ogilvie has been appointed by the government of the Dominion of Canada as Commissioner of the newly organized Yukon Territory, at a salary of $5,000 a year. He was born near Ottawa, Ont., 52 years ago, and became a land surveyor, entering the government service in June, 1875. His first permanent position was that of a chief clerk and astronomer in the Interior Department. In April, 1887, he was first sent to the Yukon region and commissioned to produce the 141st meridian, which, by the treaty of St. Petersburg, is designated as the dividing line between Canada and Alaska, from Mount St. Elias to the Arctic Ocean. On this work he was engaged for many months, and during that time made a survey of the region around the Mackenzie River and Lake Athabaska. He started on his second trip to the Yukon, June 19, 1895, and did not return for two and a half years. He was there when the rush of gold seekers to the Yukon began, and immediately became a commanding figure. His report to the Dominion government on the Yukon gold fields, which he presented upon his return, is the best description of this region that has ever been made. His appointment is a well-deserved recognition of a faithful and capable official.

OBITUARY.

Mr. Henry Amerige, formerly Superintendent of Streets of Malden, Mass., died July 14, aged 80.

Hon. Eliada S. Merrell, President of the Board of Water Commissioners of Lowville, N. Y., died July 4.

Mr. Napoleon B. Hafer, who is said to have been the first one to introduce brick paving in the West, died in Bloomington, Ill., July 10, aged 73.

Mr. F. A. Bishop, civil engineer, of Bristol, Conn., died July 4, aged 68. He went to California in 1855 and spent many years there, holding the position of Engineer to the State Board of Harbor Commissioners until 1884.

Sir Robert Rawlinson, the famous English sanitary engineer, who died on May 31, 1898, as announced in our issue of June 16, left a personal estate of $414,155. In his will, lately proven, he leaves the income of his residuary estate to Lady Rawlinson during her life, with power to dispose of one moiety of the estate. He leaves $5,000 to the Institution of Civil Engineers, and the ultimate remainder, estimated at about $175,000, will be paid to the trustees of St. Thomas Hospital.

Mr. Charles A. Ellis, contractor, of Kansas City, Mo., was drowned at Noel, Mo., July 4. He was born in Boone county, Ind., 34 years ago, and was educated at Earlham College, Richmond, Ind. In 1884 he went to Kansas City, Kan., and entered the office of the County Surveyor. He left this to enter the office of the City Engineer, and was himself appointed to the latter office five years later, in 1891. He served in this capacity for six years, and then resigned to engage in the contracting business, which he followed until his death.

Mr. Carl A. Trik, Superintendent of Bridges of the Bureau of Highways, of Philadelphia, Pa., died July 10. He was born April 28, 1841, at Wildberg, Germany, and became County Surveyor of Ulm. As one of the Royal Commissioners he established the boundary between Bavaria and Wurtemberg, and in 1881 came to this country. He became an assistant to Mr. Rudolph Hering, M. Am. Soc. C. E., of New York, and later entered the Survey Bureau of Philadelphia, as an Assistant Engineer, being in charge of the designing of the city's sewerage system. In 1888 he was appointed Superintendent of Bridges, which office he held continuously until the time of his death. About four or five months ago he was stricken with paralysis and later contracted a severe cold which developed into pneumonia.

WESTERN SOCIETY OF ENGINEERS.
Aug. 3. "Establishment of Street Grades," Chas. P. Chase. Secy., N. L. Litten, Monadnock Block, Chicago, Ill.
OHIO INSTITUTE OF MINING ENGINEERS.
Aug. 4. Summer meeting, Toledo, Ohio. Secy., Robert M. Hazeltine, Columbus, O.
TECHNICAL SOCIETY OF THE PACIFIC COAST.
Aug. 5. Secy., O. Von Geldern, 819 Market St., San Francisco, Cal.
MONTANA SOCIETY OF ENGINEERS.
Aug. 13. Secy., A. S. Hovey, National Bank Bldg., Helena, Mont.
ENGINEERS' CLUB OF MINNEAPOLIS.
Aug. 15. Secy., H. E. Smith, 1620 S. E. 4th St., Minneapolis, Minn.
WESTERN FOUNDRYMEN'S ASSOCIATION.
Aug. 17. Secy., B. M. Gardner, 1522 Monadnock Block, Chicago, Ill.
NEW ENGLAND ROAD MASTERS' ASSOCIATION.
Aug. 17. Annual meeting, Boston, Mass. F. C. Stowell, B. & M. R. R., Ware, Mass.
SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.
Aug. 18 to 20. Annual meeting at Massachusetts Institute of Technology, Boston, Mass. Secy., Albert Kingsbury, Durham, N. H.
AMERICAN CHEMICAL SOCIETY.
Aug. 22-23. Annual meeting, Boston, Mass. Secy., Albert C. Hale, 551 Putnam Ave., Brooklyn, N. Y.
AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.
Aug. 22-27. Annual meeting, Boston, Mass. Secy., F. W. Putnam, Salem, Mass.

OHIO INSTITUTE OF MINING ENGINEERS.—The annual summer meeting of this society will be held at Toledo on Aug. 4. The program includes a trip by water from Cleveland. About 100 are expected to attend.

CIVIL ENGINEERS CLUB OF CLEVELAND.—At the regular meeting held July 12 Mr. Oliver S. Hubbell, of the firm of Hubbell & Benes, delivered an address entitled "Marble versus granite." An abstract is given elsewhere in this issue. Wm. H. Searles, Secy.

INDEPENDENT TELEPHONE ASSOCIATION.—The 2d annual convention of this association was held at Chicago, Ill., June 30 and July 1-2. As the sessions were private, none but members being allowed to attend, nothing can be said of the work done, aside from the fact that a committee was appointed to propose changes in the constitution. The committee submitted a number of changes and amendments. Attendance was good, there being present representatives from independent companies in 14 states.

IRON AND STEEL INSTITUTE.—At the autumn meeting of this association scheduled for Aug. 26-27 at Stockholm, the following papers will be presented: "The Development of the Swedish Iron Industry," Richard Akerman; "The Most Prominent and Characteristic Feature of Swedish Ore Mining," Prof. G. Nordenström: "The Danger of Using Too Hard Rails," C. P. Sandberg; "The Action of Explosives on the Tubes of Steel Guns," Prof. W. C. Roberts-Austen; "Brittleness in Steel Produced by Annealing," J. E. Stead; "The Micro-Chemistry of Cementation," Prof. J. O. Arnold; "The Influence of Metalloids on Cast Iron," Guy R. Johnson.

◆

NEW PUBLICATIONS.

ARIZONA WEATHER AND CLIMATE.—Bulletin No. 27, Arizona Agricultural Experiment Station, Tucson, Ariz. By Edw. M. Boggs, Irrigation Engineer and Meteorologist. Rewritten and added to by Nathan H. Barnes, Irrigation Engineer and Meteorologist. Paper; 6 × 9 ins.; pp. 50; tables.

The tables in this bulletin give temperature, dew point, humidity, vapor pressure, sunshine, cloudiness, evaporation, wind movement and barometric pressure records for varying periods, the longest being from October, 1891, to December, 1897. Besides these tables the text describes the methods employed in making the observations and discusses some of the most important features of the climate of Arizona.

UNSTEADY FLOW OF WATER IN PIPES.—By Prof. Irving P. Church. Reprinted from "Transactions of Association of Civil Engineers of Cornell University," 1898. Pamph.; 6 × 9 ins.; pp. 44. Address Prof. C. L. Crandall, Ithaca, N. Y., Secretary Association of Civil Engineers of Cornell University.

In this pamphlet the author develops formulas for the variation of pressure in long pipes when the flow therein is checked or accelerated, and compares the results with experimental results obtained in a thesis investigation made by Mr. B. F. Lattig, a graduate of Cornell in the class of 1894. A substantial agreement is shown. The paper should be practically useful to every engineer who has to do with water power development under high heads, and may be studied in connection with the editorial discussion in Engineering News of July 8, 1897.

REPORT OF THE PROVINCIAL INSTRUCTOR IN ROAD-MAKING, ONTARIO, 1897.—Published by the Ontario Department of Agriculture and printed by order of the Legislative Assembly of Ontario, Toronto. Paper; 9¾ × 6½ ins.; pp. 71; illustrated. Address Mr. A. W. Campbell, Provincial Instructor in Road-Making, Parliament Building, Toronto, Ontario.

A year or more ago we had occasion to favorably review the report of Mr. Campbell for 1896. The present report is a similar straightforward and useful document. Country roads take up the larger part of this issue and much good advice is given as to selecting and applying the road material, in repairing the roads and in adopting methods of paying for them. Boiled down, this section calls for systematic permanent work, thorough drainage, the proper application of good materials, the use of road machinery, prompt repairs, and stone, concrete or iron bridges. In other words, it pays to build only good roads. The numerous reports from cities, towns and villages include much useful information. Mr. Campbell notes as complete and excellent the frontage-tax system in force in Blenheim, Kent Co., Ontario. While this system differs but little from many in use in the United States, Mr. Campbell's description is valuable for its explanatory detail of the requirement under the law.

BRITISH RAILWAY STATISTICS.—Pub. Doc., London. Eight pamphlets; 8½ × 13 ins.; pp. 420.

These pamphlets contain the returns by the railways of Great Britain of the statistics of train accidents for the calendar year of 1897, and of continuous brake equipment for the last six months of the same year, and a half dozen special acts authorizing the construction of as many "light railways" in different parts of the kingdom.

Altogether 34 persons were killed and 476 were injured by accidents to trains during 1897, as compared with eight killed and 549 injured in 1896. Including accidents in which no personal injury was sustained three were reported during the twelve months; 31 collisions between passenger trains; 39 collisions between passenger trains and freight trains; 34 freight train collisions; one collision between train and cars standing foul of the line; 23 collisions between trains and buffer stops; 40 derailments of passenger trains; 20 derailments of freight trains; 255 cases of trains running through gates at level crossings or other obstructions; 11 cases of fire on trains, and 5 miscellaneous accidents. Including railway accidents of all kinds, 1,165 persons were killed and 6,102 persons were injured.

The figures on continuous brakes show that on Dec. 31. 1897, 99.8% of the locomotives and 99.4% of the total passenger cars owned by British railways were provided either with vacuum brakes or Westinghouse automatic brakes.

TRADE PUBLICATIONS.

(The standard sizes for pamphlets and trade catalogues recommended by all the principal engineering societies of the United States are: 3 1-2 x 6 ins.; 6 x 9 ins., and 9 x 12 ins.)

WATER AND GAS SPECIALTIES.—H. Mueller Mfg. Co., Decatur, Ill. Pamphlets; paper.

These six pamphlets, with two to eight pages each, deal with various specialties, including the Mueller water main tapping machine, water pressure regulator, flange coupling, spiral screw and tool drivers, and an extensive line of cocks, taps, etc.

PRESS CLIPPINGS.—Robert & Linn Luce, 68 Devonshire St., Boston, Mass. Pamph.; 7 × 4½ ins.; 32 pp.; illustrated.

This pamphlet gives a history of The Press Clipping Bureau and a list of some of its patrons. The bureau was started in Boston, in 1888, and now has well established reading rooms in Boston, New York, Cincinnati and Denver. It claims to cut and deliver nearly 15,000 newspaper clippings a day at its different offices.

CONSTRUCTION NEWS.

CONDENSED LIST OF CONTRACTS PENDING WITH DATE OF OPENING BIDS.

Bids to be opened.	Work. Place.	See Eng. News.
July 21.	School building, Dayton, O.	July 7
July 21.	Sewers, Amsterdam, N. Y.	July 7
July 21.	Heating and ventilating, Syracuse, N. Y.	July 14
July 21.	Widening bridge, Paterson, N. J.	July 14
July 21.	Water tower, hydrants, etc., Chicago Junct'n, O.	July 14
July 21.	School building, Poplar Bluff, Mo.	July 14
July 21.	Sewerage system, Goldsboro, N. C. Advertised, Eng. News, July 7 and 14.	July 14
July 21.	Brick paving, Scranton, Pa.	July 14
July 21.	Pipe sewers, Brewer, Me.	July 21
July 21.	Pipe sewers, East St. Louis, Ill.	July 21
July 21.	Laying water pipe, Boston, Mass.	July 21
July 22.	Ventilating, wiring, etc., Newark, N. J.	July 21
July 22.	Brick paving, etc., East St. Louis, Ill.	July 21
July 22.	Bridge abutment, Summerville, Ont.	July 21
July 22.	street work (1 street), Duluth, Minn.	July 14
July 22.	Water-works, Cass City, Mich.	July 14
July 22.	Repairing garbage dumper, New York	July 14
July 22.	Electric light plant, Cass City, Mich.	July 14
July 22.	Main brick sewer, Louisville, Ky.	July 14
July 22.	Gravel road, Waterbury, Conn.	July 14
July 22.	Paving, Lima, O.	July 14
July 22.	Paving, Louisville, Ky.	July 14
July 22.	Water-works, Sparta, Minn.	July 7
July 22.	Hydraulic dredge, St. Louis, Mo. Advertised, Eng. News, June 23 to July 14.	June 23
July 22.	Grading, road work, etc., California, O.	June 30
July 23.	Water-works, Beatrice, Neb.	June 30
July 23.	Cement sidewalks, Washington, D. C. Advertised, Engineering News, June 23.	June 23
July 23.	Paving, Carbondale, Pa. Advertised, Eng. News, July 7 to 21.	July 7
July 23.	Embankment, etc., Shelton, Wash.	July 14
July 23.	Water pipe, Batavia, Ill.	July 14
July 23.	Iron bridges (4), Wilkes Barre, Pa. Advertised, Eng. News, July 14 and 21.	July 14
July 23.	Church building, Bay City, Mich.	July 14
July 23.	Lamp posts (300), Washington, D. C.	July 21
July 23.	Bridge, Aitken, Minn.	July 21
July 24.	Bridge work, St. Joseph, Mo.	July 14
July 25.	Church building, Holgate, O.	July 14
July 25.	County building, Chatham, Va.	July 14
July 25.	School building, Spencer, O.	July 14
July 25.	Municipal building, etc., Stratford, Ont.	July 14
July 25.	Jail, etc., Ottawa, O.	July 14
July 25.	Heating, etc., Columbus, Neb.	July 14
July 25.	Sewerage system, Kewanee, Ill. Advertised, Engineering News, July 14.	July 14
July 25.	Retaining wall, Cincinnati, O.	July 14
July 25.	Drainage ditch, Harvel, Ill.	July 14
July 25.	Lighthouse supplies, Tompkinsville, S. I. Advertised, Eng. News, July 14 and 21.	July 14

RAILWAYS.

CATSKILL & TANNERSVILLE.—Thos. E. Brown, Ch. Engr., 38 Park Row, New York, informs us that the line is under construction from Otis Summit to Twilight Park, about 4½ miles, the contract having been let to the Otis Engineering & Construction Co., New York. Grading has just been commenced on 3½ miles of road. The motive power has not yet been decided upon. Pres., C. L. Rickerson, 54 Harrison St., New York.

CENTRAL ONTARIO.—John D. Evans, Ch. Engr., Trenton, Ont., informs us that surveys will be commenced Aug. 1 on the proposed extension of this railway from Ormsby to Bancroft, via L'Amable, Ont. Financial arrangements have not yet been completed, so it is at present uncertain when construction work will begin. Pres., Stevenson Burke, Cleveland, O.

CHEAT VALLEY.—J. J. Stoer, Girard Bldg., Philadelphia, Pa., informs us that seven miles of this new line have been built and the new town of Manheim started. The proposed route is from Rowlesburg to Uniontown, via Manheim, Stoer and Warthman, Pa., a distance of 33 miles. A. P. Hamilton, Rowlesburg, W. Va.

CHOCTAW, OKLAHOMA & GULF.—Bids are asked until July 25 for about 4,500 lineal ft. of protection dike work at Calvin, Ind. Ter., and Bridgeport, Okla., over the South Canadian River. The work is in three portions, 2,600 ft., 900 ft. and 1,000 ft. long, respectively. Ch. Engr., F. A. Molitor, South McAlester, Ind. Ter.

DECKERSVILLE, OSCEOLA & NORTHERN.—Improvements in the roadbed are now being made on this line between Deckersvile, on the Kansas City, Fort Scott & Memphis R. R., and Wardell, Ark. It is also intended to extend the road through Mississippi county, Ark., and Pemiscott and New Madrid counties, Mo., to connect with the Cotton Belt Ry. at Pawpaw Junction, via Osceola and Blythesville, Ark., and Covington, Hayti, Bragadocia and Portageville, Mo., thus passing through a rich timber district. Bonds for this proposed extension have not yet been placed, and until that is done no new work can be undertaken. E. M. Ford, Vice-Pres., Deckersville, Ark.

DELAWARE.—W. C. Oliver, Andes, N Y., writes us that surveys have been completed and the right of way obtained for this line, the incorporation of which was noted in our last issue. It is expected that the contract to construct the road will be let about Aug. 1. Pres., Henry Davie, Delhi; Ch. Engr., Thos. Murray, Delhi, N.Y.

DENTON & CAMBRIDGE—M. Bates Stephens, Denton, Md., informs us that owing to the fact that the question of having the county vote a subscription to aid the construction of this line cannot come up for another year, nothing can be done at this time toward building. It is proposed to construct a railway between Denton and Cambridge, Md., about 30 miles, which will act as a feeder to the Queen Anne's R. R.

DES ARC & NORTHERN.—W. H. Hipolite, Ch. Engr., Poplar Bluffs, Mo., writes us that construction will probably begin July 25 on the four-mile extension into Des Arc, and that it is hoped to complete the work about Sept. 15. New stations will be required at Higginson and Des Arc, Ark.

DULUTH & NEW ORLEANS.—Surveys for this new line are expected to be commenced shortly in Winnebago county, Ia. The company was incorporated June 10, with a capital stock of $300,000, to construct a railway from Duluth, Minn., to some convenient Gulf port, with headquarters at Nevada, Ia. The first 30 miles will be built as soon as possible. Robert B. Hunter, Ch. Engr., Mitchell, Ia.

DULUTH & NORTHERN MINNESOTA.—R. N. Marble, Asst. Gen. Mgr., Duluth, Minn., writes us that the grading is about three-quarters and the bridging about one-third finished on the first six miles of this line. The work is being done under the direction of the superintendent by day labor. Pres., M. S. Smith, Detroit, Mich.

EAST CAROLINA.—James Pender, Secy., Tarboro, N. C., informs us that the proposed route for this line, from Daviston to Crisp, N. C., a distance of 11 miles, has been surveyed twice, and about seven miles have been located, and the right of way obtained; there are already four miles of road built and in operation. Part of the capital stock has been secured, and the construction work will probably be done by the company. Pres., Henry Clark Bridgers, Tarboro, N. C.

FLORIDA & ALABAMA.—This company has applied for a charter in Alabama, to have a capital stock of $200,000, to construct a railway from Garland, on the Louisville & Nashville Ry., by River Falls, to Geneva, Ala., and thence into Florida. The incorporators are G. B. Frierson, P. J. Grant, Henry Stanley and E. C. Lewis, of River Falls, Ala., and J. H. Eakin, John S. Lewis and E. L. Moore, of Nashville, Tenn.

GALLATIN.—Frank A. Hall, Vice-Pres. and Gen. Mgr., of Bozeman, Mont., is quoted as saying that this company intends to begin work at once on the proposed extension of this line from Three Forks, Mont., up the Gallatin River to Yellowstone Park. A preliminary survey has been made.

GEORGIA.—Henry T. Clarke, care of B. F. Finney, 99 Bay St., Savannah, Ga., is constructing a connecting link of railway, 25 miles long, six miles of which has already been constructed, between two systems of railways. This link, when completed, will shorten the distance ten miles. Mr. Clarke desires to have a bond issue of $200,000 for the purpose of completing this road. Parties who desire information and prospectus of proposed work may address Mr. Clarke.

GROVE HILL & WHATLEY.—A. S. Johnston, Grove Hill, Ala., informs us that this proposed standard-gage road will run from Grove Hill, the county seat of Clarke county, to Whatley, six miles, connecting with the Mobile & Birmingham. A large amount of the stock has already been subscribed, and the survey will be made next week. Work will probably begin by Aug. 15.

GULF, BEAUMONT & KANSAS CITY.—Reports state that construction will soon commence on a 17-mile extension of this line from Silsbee, Tex., north. An extension is also proposed from Kirbyville to Tanaha, via Jasper, Tex., 100 miles. John H. Kirby, Vice-Pres. and Gen. Mgr., Houston.

GULF, COLORADO, & SANTA FE.—It is announced that a contract has been made by this company with the St. Louis Southwestern R. R. Co., whereby the former will have an entrance for its trains into Sherman, Tex., over the tracks of the St. Louis Southwestern. It is believed that this new arrangement will affect a large amount of business in northern Texas. C. F. W. Felt, Ch. Engr., Galveston, Tex.

JAMAICA.—Press reports from Kingston, Jamaica, state that the local government has assumed control of the Jamaica Ry., as the West India Improvement Co., which controlled the line, was unable to meet its liabilities. As the government cannot operate it to advantage, it is expected that the property will be sold.

LITTLE COAL RIVER.—H. J. Tondy, Huntington, W. Va., a member of this company, the incorporation of which was noted in our issue of July 7. writes us that the preliminary survey has been made and the right of way secured for nearly the whole length. The contract has been let to Henry S. Hopkins, St. Louis, Mo. Pres., L. Roswell Sheffer, New York; Ch. Engr., Mr. Leete, Huntington, W. Va.

PENNSYLVANIA LINES WEST OF PITTSBURG.—The Pittsburg, Fort Wayne & Chicago division of this system is said to have completed the regrading of its line from Rochester to New Brighton, three miles, and to be about to begin the laying of a fourth track from Baden to New Brighton, six miles, and the general improvement of the terminal yards at Conway. The improvements will cost about $70,000, The extension and improvements will be made to facilitate the ore and coal business on the Lake Erie lines, for which the yards act as the terminal. Supt., A. B. Starr, Allegheny, Pa.

PONTOTOC & STARKSVILLE.—We are informed that the survey for this proposed railway will be made as soon as the services of a competent engineer can be secured. The company was recently incorporated in Mississippi, as stated in our issue of July 7, to build a line from Pontotoc to Starksville, via Algona, Houlka, Houston and Sparta, Miss., a distance of 60 miles. Communication on the subject of surveys is solicited by N. W. Bradford, Houston, Miss. Pres., N. B. Crawford, Atlanta, Miss.

STOCKTON & TUOLUMNE.—Surveys for this proposed railway from Stockton to Summerville, via Sonora, Cal., 65 miles, are completed from Stockton to the Stanislaus River, a distance of 45 miles, and it is estimated that the cost of constructing this section of the road will be $8,927 a mile. Surveys are also in progress on the rest of the route, and it is said that Charles Erickson & Son, the contractors, are at work along the line. The company expects to use 60-lb. steel rails on the first 25 or 30 miles, which is to cross the San Joaquin Valley, and 65-lb. rails on the mountain division; 3,000 cross ties will be laid on each mile of main track. Pres., Mrs. Annie Kline Rikert; Ch. Engr., Henry A, Brainerd, with offices at Grand Hotel, San Francisco, Cal.

UNION COVE & VALLEY.—G. E. Howe, Ch. Engr., Union, Ore., informs us that the surveys have been made and grading has been commenced on this steam line from Cove to Union, 12 miles. The work is being done by day labor. Pres., E. P. McDaniel, Cove, Ore.

UNION PACIFIC.—J. B. Berry, Ch. Engr., Omaha, Neb., informs us that no extension to this system are contemplated, and that the only improvements projected include a small number of new sidings and a few trestles.

STREET AND ELECTRIC RAILWAYS.

EAST ROCHESTER, N. H.—Wm. A. Roberts is reported to be interested in the project to build an electric railway from this place to Somerville.

BURLINGTON, VT.—Surveys are now being made for the Burlington & Grand Isle R. R., as far as Malletts Bay. Seneca Haselton may be addressed.

AUBURN, MASS.—The selectmen have granted a franchise to the Worcester & Webster Electric Ry. Co. to build an electric railway through this place, according to report. E. E. Carpenter is a member of the company.

BOSTON, MASS.—The railroad commissioners have approved the plans of the Boston Elevated Ry. Co., according to report.

FRAMINGHAM, MASS.—J. J. Hennesy, Supt., writes us that the Framingham, Southboro & Marlboro St. Ry. is nearly finished and will probably be running by Aug. 1.

PLYMOUTH, MASS.—Bids are asked until July 28 for building the first section of the Plymouth & Sandwich St. Ry., from Hotel Pilgrim to Manomet P. O., and also for the first and second sections, combined, from Hotel Pilgrim to Fresh Pond. Engrs., Harriman Bros., 3 Somerset St., Boston. Address D. E. Damon, Plymouth.

BRISTOL, R. I.—The town council granted a hearing July 7 to the Barrington, Warren & Bristol St. Ry. Co. on its application for a franchise in this place. No decision was rendered. Albert F. Cotter, Pres.

HARTFORD, CONN.—E. S. Goodrich, Pres. of the Hartford St. Ry. Co., was heard by the street board July 13 in regard to plans for the construction of a street railway on Charter Oak and Huyshope Aves., for which the company has asked for a franchise. It was voted to recommend the construction of the road to the council.——The Suburban Electric Ry. has decided to extend its line from Unionville to Collinsville, seven miles, through the Farmington valley. The work will be done by the company; employing day labor.

BUFFALO, N. Y.—The contract for the construction of the proposed Buffalo, Hamburg & Aurora Electric Ry. is about to be let, according to report. U. L. Upson, Secy. and Gen. Mgr.

BUFFALO, N. Y.—The Buffalo, Tonawanda & Niagara Falls Electric R. R. opened for traffic an extension, July 16, beginning at Tonawanda and O'Neil Sts., on northerly limits of the city, thence to Niagara St. and along it about one mile to a ferry on the Niagara River, running to Grand Island. The line will be further extended along Niagara St. to Tonawanda, thus forming another electric line between Niagara Falls and this city. Henry B. Smith, Bay City, Mich., is the principal stockholder.

CLINTON, N. Y.—The New Hartford & Clayville Electric R. R. Co. is reported to have petitioned village trustees for a franchise to build a street railway through this place. The company has also asked the town board of Kirkland for a similar franchise. C. L. Fitchard, Utica, is interested.

HUDSON, N. Y.—It is reported that the Jansen Kill Power Co. has bought the Hudson St. Ry. and will extend it to Claverack and Philmont, building two power houses of a total capacity of 2,600 to 2,800 HP., one of which will be at Bingham's Mills, on Jansen Kill, and the other four miles below. The electricity will also be used for manufacturing purposes in the city.

LOCKPORT, N. Y.—The Buffalo & Lockport Electric Ry. Co., which was reported in our issue of June 16 to have bought the Lock City Electric Ry., has been granted a franchise to build an extension in West Ave. and Transit St. with the privilege of transporting freight between 11 p. m. and 6 a. m. W. Caryl Ely, Pres., Niagara Falls.

LONG ISLAND CITY, N. Y.—It is reported that a mortgage of $1,500,000 has been filed by the New York & North Shore Ry. Co. to enable it to build the proposed line from the present terminus in Middle Village to Flushing, via Richmond Hill and Jamaica. It is also proposed to build an extension from Flushing to Bayside and Manhasset, via Whitestone.

NEW YORK, N. Y.—The Metropolitan St. Ry. Co. has asked permission of the dock board to build a power house on the wharves between 95th and 96th Sts., on the East River, to furnish electric power to its lines of cars run by the underground electric system. C. E. Warren, Secy.; A. C. Tully, Pur. Agt.

NIAGARA FALLS, N. Y.—Geo. P. Smith, North Tonawanda, it is stated, has asked for a franchise for an electric railway in this city. A hearing will be granted him the latter part of this month.——It is also reported that the Niagara Falls St. R. R. Co. has asked for a franchise to build an electric railway line on Niagara St., from the State Reservation. The railroad commissioners approved the construction of the road about a year and a half ago, but nothing has been done. The company has lately been reorganized and the work will now be pushed to completion.

NORTH TONAWANDA, N. Y.—The injunction obtained by the city against the Buffalo & Niagara Falls Electric Ry., restraining it from constructing a turnout and switch on Sweeney St., has been dissolved and the work will be completed at once, connecting the above road with the Erie R. R. W. Caryl Ely, Pres.

ONEONTA, N. Y.—Owen Phillips, Engr., writes us that the Oneonta & Otego Valley R. R. is now completed and will be running from this place to West Oneonta in a few days. There are 7¼ miles of track, including three branches, and an extension to Laurens, 5 miles, has been located.

PEEKSKILL, N. Y.—The highway commissioners of Cortland have granted a franchise to the Peekskill Traction Co. to build an electric railway in that town, according to report.

PENN YAN, N. Y.—The Penn Yan & Savona R. R. Co. has been organized to build an electric railway from this place to Savona, via Keuka. J. D. Nares is the promoter of the road; Geo. F. Andrews, Pres., Owego.

SYRACUSE, N. Y.—The Eastwood R. R. Co. has asked for a franchise to enable it to construct a line of electric railway from this city to East Syracuse, via Eastwood, according to report. R. E. Drake and Clinton S. Carr are attorneys for the company.

WATERTOWN, N. Y.—The Black River Traction Co. has decided to extend its line to Dexter in the fall, according to report. J. A. Lebkuecher, Newark, N. J., Pres.; Geo. H. Walker, Secy.

ELIZABETH, N. J.—The roads committee of the board of freeholders reported July 14 on the plan of widening Westfield Ave., from this city to Plainfield, 12 miles, the cost to be covered by selling a franchise for a trolley line over the entire length to the highest bidder. The work is estimated to cost $300,000 and an additional $50,000 if the avenue is widened through Cranford. Bids for the franchise will be called for in a few days. John Kean is reported to have offered $100,000 for it and the North Jersey Electric St. Ry. Co. is also anxious to secure it.

WESTFIELD, N. J.—The Westfield & Elizabeth Ry. Co. has asked for a franchise through South Ave. A hearing will be granted July 21. A. A. Gaddis represents the company.

DOYLESTOWN, PA.—Thos. P. Chambers, Pres., Newtown, writes us that the Newtown Electric St. Ry. Co., which proposes to extend its line from Newtown to this place, 13¾ miles, via Wightstown, Penn's Park, Wycomb, Forestville and Furlong, as stated in our last issue, has completed surveys, obtained the right of way, secured the necessary capital and will probably let the contract within a week.

ERIE, PA.—The Erie Electric Motor Co. informs us that it does not contemplate making any extensions at present.

READING, PA.—A. J. Eberly, Philadelphia, has the contract to construct the electric railway from Boyertown to Stony Creek, near this city, via Pleasantville, for the United Traction Co.

BALTIMORE, MD.—The Security & Trading Co. has purchased all the property of the Columbia & Maryland Ry. Co. for $450,000, and has sold the Baltimore end to the Baltimore Consolidated Ry. Co. for $250,000. The last named company will complete the line to Ellicott City. The Washington end of the Columbia & Maryland has been absorbed by the City & Suburban Co., Washington, D. C., the officers of which are: O. T. Crosby, Pres.; Dana Stevens, Secy.; S. C. Cooper, Treas.

MARTIN'S FERRY, W. VA.—The Martin's Ferry council has granted a franchise to the Wheeling St. Ry. Co. to build an extension from its present terminus to the north end of town.

ATHENS, GA.—The Athens Electric St. Ry. Co. will extend its line to Mitchell's bridge in the fall. W. S. Holman, Pres.

DAYTON, O.—The Dayton & Germantown Traction Co. has been incorporated with $10,000 capital to build an electric railway in this city. The incorporators are: Fred. Shoop, Isaac J. Bassatt, Noah Coler, T. P. Meredith and Theo. C. Lindsey.——The city council has granted a franchise to the Dayton, Spring Valley & Wilmington Traction Co. to build an electric railway in this city, according to report.

SANDUSKY, O.—The Sandusky Electric St. Ry. was sold July 9 to Henry Everett, E. W. Moore and Barney Mahler, of Cleveland, and W. H. Price and Chas. H. Stewart, of Norwalk, for $60,024.

MASON, MICH.—A mass meeting was held in this place July 11 in the interests of the Lansing, Dexter & Ann Arbor Electric R. R., the promoters of the road having asked for $7,000 bonus from this town, which will probably be raised.

CHESTER, ILL.—A company is being organized, according to report, to build an electric railway from Belleville to this place, via Smithton, Hecker, Red Bud, Ruma, Evansville and Ellis Grove.

EAST ST. LOUIS, ILL.—The East St. Louis & Collinsville Electric R. R. Co. has been incorporated with $2,500 capital, by Wm. Ortgrier, T. T. Ramey and W. E. Hadley.

ROCKFORD, ILL.—The City Ry. Co. and the Rockford Traction Co. have consolidated under the name of the Rockford Ry. Light & Power Co. R. N. Baylies, Pres.

EAU CLAIRE, WIS.—E. J. Matchett, Osseo, is reported to have been awarded the contract to construct 30,000 yds. of track for the Chippewa Valley Electric Ry.

KENOSHA, WIS.—The Milwaukee, Racine & Kenosha Electric R. R. Co. has applied for a franchise to build a street railway in this city, according to report.

RACINE, WIS.—The Wisconsin Inland Lakes & Chicago Ry. Co., which was recently organized with $10,000,000 capital, to build an electric railway connecting all of the Wisconsin inland lakes, July 6 filed a trust deed for that amount on the 500 miles of track to be built between Chicago and Watertown, including branch lines to Milwaukee, Wilmette, Madison, Elgin and Desplaines. Construction will be begun as soon as a franchise is secured in this city. Alfred E. Case, Actg. Pres.

WALWORTH, WIS.—The town board has granted an extension of its franchise to the Harvard & Geneva Lake Electric Ry., according to report. H. T. Windsor, Colburn's Hotel, Fontana, may be addressed.

MINNEAPOLIS, MINN.—The board of trade of this city at its meeting July 5 passed a resolution advising the building of an electric railway between Minnehaha and Fort Snelling.

KANSAS CITY, MO.—The Brooklyn Ave. St. Ry. Co. has been granted a franchise to build its proposed line on Grand Ave., from 33d St. to 13th St., as noted in our issue of July 7.——L. E. Myers, Chicago, has been awarded the contract for the construction of the Broadway line of the Metropolitan St. Ry. A. H. Holmes, Gen. Mgr.; E. Butts, Engr.

PASADENA, CAL.—The Los Angeles Terminal Ry. Co. has been granted a franchise to build an electric railway in this city. Bids are asked until Aug. 15 for the purchase of this franchise.

SAN FRANCISCO, CAL.—The board of supervisors has granted three street railway franchises to the Market St. Ry. Co. for lines on Army St., San Bruno and Precita Aves.; Stanyan and Frederick Sts. and Parnassus and Fifth Aves.; Bosworth and Berkshire Sts.——A franchise has also been granted to the San Francisco & San Mateo R. R. Co. to construct an electric line on Howard St. and East St. to the Union Ferries Depot.

ELECTRIC LIGHT AND POWER.

NORTH GORHAM, ME.—Press reports state that the Cumberland Illuminating Co., Deering, Me., will soon build a power plant on the Presumpscot River. It is stated that the power house, to be 36 × 46 ft., is now being built. Geo. W. Brown, Mgr. Deering Electric Lighting Co., is interested.

OLDTOWN, ME.—The Bodwell Water Power Co., Pres., Chas. V. Lord, Bangor, Me., has engaged Lockwood, Greene & Co., Hydraulic Engrs., Boston, Mass., to prepare plans, etc., for the proposed power plant on the Penobscot River, near this place. Treas. and Clk., A. H. Brown.

WESTBROOK, ME.—The question of building a municipal plant in this place is being considered by the council. Councilman I. A. Burgess may be addressed.

SOMERSWORTH, N. H.—Geo. F. West, Portland, Me., has submitted estimates for a municipal plant to cost $14,504. The plant will have 100 1,200-c. p. arc lights.

BRATTLEBORO. VT.—Efforts are again being made for the construction of a dam and power plant on West River, to cost about $50,000.

NEWPORT, R. I.—The council is considering two resolutions authorizing the committee to ask for bids for lighting the streets with 110 2,000-c. p. arc lights for three, five or ten years, or for constructing a municipal plant of 300 arc lights capacity.

CLINTON, N. Y.—T. T. Thompson, Pres. Village, writes us that this town has given up the idea for the present of lighting the streets with electricity.

GREENSBURG, PA.—A. M. Crawford, Burgess, writes us that no steps have yet been taken for the erection of a plant in South Greensburg.

PHILADELPHIA, PA.—Stacey, Reeves & Son, 1611 Filbert St., are securing estimates for a 1-story power-house to be erected at 19th St. and Allegheny Ave., for the Electric Storage Battery Co. It will be 35 ft. square, brick and iron construction.

RIDLEY PARK, PA.—It is reported that the council is considering the question of asking for bids for lighting the streets of this borough. It is possible, however, that a contract, without advertising, will be made with the Beacon Light Co.

WEST CONSHOHOCKEN, PA.—The Conshohocken Electric Co. submitted the lowest bid July 6 for lighting this place with electricity for five years. The only other bid was that of Dr. Lefferts, representing a syndicate.

OAKLAND, MD.—R. S. Jamison, Mayor, writes us that the council as yet has not taken action in regard to a plant and water-works.

WASHINGTON, D. C.—Bids are asked by the district commissioners until July 23 for furnishing 300 lamp posts.

SUFFOLK, VA.—John B. Norfleet, Chn. Com., writes us that the council has made a contract with the old electric company for lighting this city for three years.

WINCHESTER, VA.—Wm. R. Willis, Councilman, writes us that the council is considering the question of a municipal plant, to be operated in connection with the pumping station owned by the city. There are two Corliss engines at the pumping station suitable for the purpose. While the town recently voted by a large majority for the plant the council majority does not favor the plant. The plant is planned to have a capacity for 70 2,000-c. p. arc lights.

SPARTANBURG, S. C.—We are informed that a company has secured the contract to light this place for a term of years. The necessary power will be obtained by developing the water power near here. William Whitner and Frank Whitner, Anderson, S. C., are interested.

ARCADIA, FLA.—The clerk writes us that steps have not yet been taken in regard to erecting a plant.

JACKSONVILLE, FLA.—C. O. Patterson, Supt. Electric Light Plant, has made plans and estimates for extending the light wires through Springfield, Campbells Addition, La Villa, etc. In La Villa alone it is proposed to construct three circuits of 60 arc lights and nine miles of wire each.

CULLMAN, ALA.—Jas. E. Clark, owner of the franchise of the Cullman Water & Lighting Co., writes us that the company is being organized. Bids for furnishing and constructing the plant will be asked about Sept. 1. The plant will have a capacity for 21 1,200 to 2,000-c. p. arc and 1,000 16-c. p. incandescent lights; estimated cost, $15,000.

HENDERSON, KY.—R. P. Farnsworth writes us that the council lacks one vote of a majority in favor of the proposed plant.

AKRON, O.—The council has voted to award a contract for lighting the city to the Akron St. Ry. & Illuminating Co. The question will have to be voted upon by the city commissioners.

FOSTORIA, O.—Press reports state that the directors of the Fostoria Light & Power Co. are considering an offer for the purchase of the plant by a Philadelphia company, represented by S. R. Bullock, of that city.

McARTHUR, O.—J. W. Darby. W. J. Kennard and Paris Horton are on the committee to build the proposed plant.

MINSTER, O.—Bids are asked until Aug. 16 for furnishing the materials and for constructing a plant. There will be required an 80-HP. engine, two 54-in. × 14-ft. boilers, a feed pump, three 40 K-W. dynamos, etc. Consult. Engr., G. A. McKibben, Van Wert, O.; Clk., August Schunck.

INDIANAPOLIS, IND.—Bids are asked by the board of trustees of the Indiana Institution for the Education of the Blind until Aug. 2 for furnishing and constructing a plant.

DECATUR, MICH.—Geo. S. Pierson, Kalamazoo, Mich., is preparing plans for a plant for this place, for which $16,000 in bonds was voted recently.

FENTON, MICH.—Rev. F. S. Thompson is reported to have purchased the plant in this city for $9,000.

GRAND RAPIDS, MICH.—The council has sustained Mayor Perry's veto of the contract for the electric light plant. The board of public works was instructed July 11 to prepare new specifications and readvertise for bids.

YALE, MICH.—Bids are asked until Aug. 2 for furnishing and constructing a plant, as advertised in Engineering News July 7. (Postponement from July 26.) E. F. Fead, Village Clk.

BRACEVILLE, ILL.—This place has voted to build a plant, according to reports.

RIDGEFARM, ILL.—The board is reported as considering the question of building a plant. C. M. Harrold, Clk.

ROCKFORD, ILL.—The Rockford Ry., Light & Power Co., recently reorganized by the consolidation of the two companies, has applied for an extension of the franchises, according to reports.

MILWAUKEE, WIS.—Bids were received July 18 by H. J. Esser, Arch., 902 Pabst Bldg., for constructing a power station is this city to be 100 × 130 ft.

SUPERIOR, WIS.—The council has let a contract for furnishing 150 2,000-c. p. arc lights to the Superior Water, Light & Power Co.

GAYLORD, MINN.—Bids are asked until July 28 for furnishing and constructing a plant, as stated in our advertising columns. C. W. Clasen, Village Recdr.

MITCHELL, S. DAK.—F. C. Duffy, Ripon, Wis., owner of the plant in this city, has submitted a proposition to either lease or sell the plant to the city.

KANSAS CITY, KAN.—Local papers state that Lemuel Crosby has secured the contract for building the new electric light plant for the Consolidated Electric Light & Power Co., on the west of the Kaw River bridge. This plant is designed to furnish electric light and power for Kansas City. The building alone will cost about $25,000, and some $50,000 more will be required for the engines, dynamos, etc. There will be 15 dynamos of an aggregate of about 1,000 HP. The smokestack will be 150 ft. high and 8 ft. inside diameter. The building will be 100 × 140 ft., two stories high.

BATESVILLE, ARK.—Owen Ford, Consult. Engr., Security Bldg., St. Louis, Mo., writes us that the contracts for furnishing and building a plant and water-works has been let to G. Jaeger, Rich Hill, Mo., at $24,720.

PARIS, TEX.—We are informed that the Paris Light & Power Co., recently incorporated, is a consolidation of two companies.

REDLANDS, CAL.—The stockholders of the Redlands Electric Light & Power Co., 14 West State St., will meet July 21 to consider the question of increasing the capital stock from $200,000 to $500,000 for making improvements, etc., to the plant. Secy., Fulton G. Ferand.

SAN FRANCISCO, CAL.—The supervisors have received bids for lighting the city with electricity by districts for a term of two years from Aug. 1. John A. Russell, Clk.

IDAHO FALLS, IDAHO.—An election will be held Aug. 9 to vote on the question of issuing $25,000 in bonds for the purchase of the plant and water-works, according to reports.

BUENOS AYRES, ARGENTINE REPUBLIC.—Press reports state that a German electric light and traction company has been formed in Buenos Ayres, with a capital of $5,000,000. It has acquired some electrical railway privileges in the capital, and is to construct a central station which will cost about $800,000. Gaster Fredersking is the principal party interested in this undertaking.

NEW COMPANIES.—Tuxedo Park Water & Electric Light Co., Towson, Baltimore, Md.; to furnish water and electric light to the residents of Tuxedo Park; G. O. Wilson, H. O. Leonard, John Neubaker, Fred E. Wilson, William F. Smith.

Cleveland Electric Co., Cleveland, O.; $4,400; W. P. Bowman, F. C. McMillan, James E. Matthews, F. W. Post, W. C. Stevens, Cleveland.

Vigo Light & Power Co., Terre Haute, Ind.; $50,000; W. R. McKeen, Herman Hulman, James A. J. Crawford, J. A. Crawford.

Western Electric Co., Chicago, Ill., and Detroit, Mich.; $1,000,000.

Kearney Power & Irrigation Co., Kearney, Neb., and 145 South 11th St., Lincoln, Neb.; $230,000; W. A. Lindley, J. P. Hibard, Theo. Tychsen.

Newman-Spranley Co., Ltd., New Orleans, La.; $30,000; to conduct a general electrical business; J. K. Newman, Isidore Newman, Edgar Newman, C. H. C. Brown and William T. Spranley.

Standard Electro Vapor Motor Co., New York, N. Y.; $50,000; S. W. Warner, B. L. Warner and W. M. Warner, Yonkers.

Manhattan Illuminating Co., New York, N. Y.; $100,000; to manufacture devices for use with gas, hydrocarbon oils or other fluid combustibles for lighting purposes; De Witt H. Palmer. Brooklyn; William Walters and Chas. R. Lindsay, Jr., New York.

BRIDGES.

HARTFORD, CONN.—The city attorney has been instructed to procure an order for the construction of a bridge over the railroad tracks at Broad St.

HERKIMER, N. Y.—The town has voted to appropriate $13,500 for constructing the proposed bridge across West Canada Creek.

WHITE PLAINS, N. Y.—The county supervisors have voted to issue bonds for the construction of bridges over Rowley Brook and Hastings Ravine on the Warburton Ave. extension.

PITTSBURG, PA.—Reports state that a contract has been awarded to the Pittsburg Ornamental Works for constructing 29 arches to cost about $6,820, to decorate the thoroughfares for the Knights Templars triennial conclave.

ANNAPOLIS, MD.—Bids are asked until July 26 for converting the Severn River rolling draw bridge into a pivot draw, and for constructing two pile bridges. A. K. Starlings, County Clerk. Address the Engineer, 15 East Lexington St., Baltimore.

BALTIMORE, MD. — The county commissioners have awarded a contract to the Wrought Iron Bridge Co., Canton, O., at $2,397, for constructing a bridge 119 ft. long and 16 ft. wide, over Big Gunpowder River, near Parkton.

LEXINGTON, KY.—Alex. Pearson, J. V. Nichols and others, have petitioned the fiscal court for an appropriation of $2,600 to erect a viaduct on the Maysville and Lexington turnpike.

BATAVIA, O.—Bids are asked until Aug. 10 for constructing a 160-ft. bridge over the east fork of Little Miami River. John W. Davis, County Audr.

CINCINNATI, O.—Bids are asked until Aug. 10 for constructing an iron truss bridge over the Miami Canal, on Township Ave. E. L. Lewis, County Audr.

CLEVELAND, O.—Bids are asked until Aug. 17 for furnishing the material and for constructing the substructures for a bridge over the Cuyahoga River, near the South Park Station, and for a bridge over the Ohio Canal, on the Howard Road, in Newburg township. J. C. Dorn, Clk. Bd. County Comrs.

MASSILLON, O.—The Massillon Bridge Co. has been awarded a contract to construct a foot bridge 600 ft. long over the river and canal; estimated cost, $2,000.

NEW PHILADELPHIA, O.—Bids are asked until July 28 for constructing an iron bridge over the Tuscarawas River, according to reports. E. C. Browne, County Audr.

SIDNEY, O.—Bids are asked until Aug. 3 for constructing a hoist bridge at Water St., according to reports. J. S. Laughlin, County Audr.

SAGINAW, MICH.—Reports state that the street railway company has made a proposition to the council to construct a bridge for its own use at Johnson St., to cost about $40,000.

CHICAGO, ILL.—Bids are asked until Aug. 3 for furnishing the material and constructing 11 superstructures over the main drainage channel, as advertised in Engineering News June 2. (Postponement from July 20.)

CHICAGO, ILL.—Bids are asked until July 29 for removing and reconstructing the 61st St. viaduct, between Clark and State Sts. L. E. M'Gann, Comr. Pub. Wks.

AITKEN, MINN.—Bids are asked until July 23 for constructing a bridge across Ripple River at Knox St. F. M. Shook, Pres.

DES MOINES, IA.—A petition has been presented to the council for the construction of a bridge over the Des Moines River at East Sixth St.

TOLEDO, IA.—Bids are asked until July 28 for constructing a steel bridge with a span of 168 ft., on caisson foundation, two miles west of Chelsea. C. H. Miller, County Audr., Toledo.

WAVERLY, IA.—Bids are asked by the county supervisors for constructing the superstructure of a bridge 38 ft. wide across the Cedar River, to cost about $15,000.

CENTRALIA, WASH.—Bids are asked until Aug. 1 for constructing a bridge with a span of 260, 270 or 280 ft. over the Chehalis River. Allen P. Schooley, County Audr., Chehalis.

CHEHALIS, WASH.—Bids are asked until Aug. 1 for constructing bridges of 160, 75 and 80 ft. long; also for repairing the jetty at the Toledo bridge. Allen P. Schooley, County Audr.

CLAQUATO, WASH.—Bids are asked until Aug. 1 for the construction of a 200-ft. span bridge over the Chehalis River. Allen P. Schooley, County Audr., Chehalis.

OLYMPIA, WASH.—Bids are asked until Aug. 6 for constructing a crib around the south piers of the Rochester and Grand Mound bridges. R. A. Graham, County Audr.

SPOKANE, WASH.—A contract was awarded to the Gillette-Herzog Mfg. Co., Minneapolis, Minn., at $8,197, on July 5, for constructing a trestle 500 ft. long to carry the water mains over the Spokane River. B. H. Fowle, Secy.

HILLSBORO, ORE.—The county commissioners will replace the bridge over Dairy Creek with a 46-ft. span truss bridge.

BLOOMFIELD, CAL.—Bids are asked by the county clerk at Santa Rosa until Aug. 2 for constructing a bridge on the Monterey Road.

LODI, CAL.—Bids are asked until Aug. 2 for constructing a steel and iron bridge across the Mokelume River, near this place. G. A. Atherton, County Engr.; Otto Grunsky, Clk., Stockton.

SANTA ROSA, CAL.—J. A. McMahon, San Francisco, has been awarded a contract by the county supervisors for constructing a bridge across Russian River, at $3,895, and for a new span for the Alexander bridge, at $4,465.

ST. HERMENEGILDE, QUE.—Bids are asked until July 30 for constructing a bridge across Kinney Brook, according to reports. Address J. D. Dupont.

QUEBEC, ONT.—Engineer Hoare, of the Quebec Bridge Co., has made a report on the proposed bridge construction for this year, involving a cost of about $500,000. Bids will probably be asked by Sept. 1, according to reports.

SUMMERVILLE, ONT.—Bids are asked until July 22 for constructing a concrete or stone abutment for a bridge over the Etobicoke River, on Dundas St. J. McDougall, County Engr., Toronto.

BUILDINGS

FRAMINGHAM, MASS.—This town has voted to borrow $35,000, to be used for school purposes.

NORTHAMPTON, MASS.—Reports state that the trustees of Smith College have accepted plans by York & Sawyer, Archs., New York, for the erection of Seelye Hall, to cost $50,000.

NEWPORT, R. I.—Bids are asked until July 26 for the erection of a naval station. W. K. Van Reypen, Surgeon-Gen., U. S. N., Navy Dept.

NEW HAVEN, CONN.—Bids are asked until Aug. 1 for metal work for the New Haven Harbor breakwater light, as stated in our advertising columns. Lt.-Col. D. P. Heap, U. S. Engrs., Tompkinsville (S. I.), N. Y.

BUFFALO, N. Y.—Bids are asked by the department of public works until July 29 for the erection of a 2-story, 8-room brick addition to School No. 28, at Abbott Road and Triangle St. Secy., R. G. Parsons.

NEW YORK, N. Y.—The contract for the iron work on the new 10-story business building, 28 × 175 ft., to be erected at Broadway and Walker St., has been awarded to J. B. & J. M. Cornell, 26th St. and 11th Ave. Archs., Wm. H. Birkmire, 320 Broadway.——Plans are being prepared, according to reports, for three 5-story flat buildings to be erected on 101st St., near Park Ave., for Nathan Goldstein, 144 Monroe St. and Simon Preusky, 1921 2d Ave., at a cost of $60,000. Arch., S. D. Cohen, 203 Broadway.—Robinson & Wallace, 123 East 23d St., are said to have been awarded the contract for the erection of new buildings for the New York Hospital, 15th and 16th Sts., near 5th Ave., to cost about $500,000. Archs., Cady, Berg & See, 31 East 17th St.——Plans have been filed by Robert Kelly, 274 East 74th St., for six 3-story brick dwellings, on Hamilton Terrace, near 141st St., to cost $78,000. Arch., William Strom, 44 Broad St.; by Bridget Cooney, 220 9th St., for four 5-story brick tenement buildings on 63d St., near West End Ave., to cost $72,000. Arch., S. Sass, 23 Park Row; Frederick Klingman, 132 East 44th St., for a 7-story brick apartment house at 107th St. and West End Ave., cost $70,000. G. F. Pelham, Arch.; Joseph Polstein and Wm. Feinberg, for a 6-story brick flat, Nos. 242 to 246 Madison St., to cost $54,000. Michael Bernstein, Arch.

NEW YORK, N. Y.—John F. O'Rourke, 44 Broadway, has been awarded a contract for furnishing eight pneumatic caissons for the foundation of the new residence to be erected by Mrs. M. L. V. Shepard, Scarsboro, N. Y., at Nos. 11 and 13 East 62d St., to cost $75,000. Archs., Haydell & Shepard, 156 5th Ave.——Plans have been filed by James A. Timpson, 130 St. Ann's Ave., for a 5-story brick flat, on Melrose Ave., near 157th St., to cost $19,000. W. C. Dickerson, Arch.

NEWARK, N. J.—Bids are asked until July 22 for plumbing, heating, ventilating and electric wiring, in the county court house. C. W. Heilman, Chn. Com., Bd. Freeholders.

PATERSON, N. J.—Official notice is given that the True Reformed Dutch of Acquackanonk intends to erect a new church building adjoining its present structure.

PHILADELPHIA, PA.—Doyle & Doak, 133 South 15th St., Philadelphia, have been awarded a contract at $175,000 for constructing the buildings of the Jefferson Medical College. Arch., J. H. Windrim.

PHILADELPHIA, PA.—Robert A. Pitts, Arch. and Builder, 223 South 3d St., has been awarded a contract to construct 93 3-story brick and stone dwellings on Hazel Ave. and 48th and 49th Sts., to cost $300,000.

PHILADELPHIA, PA.—Bids are asked by Supt. J. H. Vail, of the Pennsylvania Light & Power Co., 10th and Sansom Sts., for alterations and additions to station 5, Callowhill St. James H. Windrim, Arch.

YORK, PA.—Bids are asked until Aug. 4 for alterations and additions to the county court house. Arch., J. A. Dempwolf, York.

ANNAPOLIS, MD.—A contract was awarded to Taylor & Chance, Annapolis, at $12,671, on July 6, for erecting a library and laboratory for St. James' College.

BALTIMORE, MD.—The Consolidated Ry. Co. has awarded a contract to John Hiltz for the construction of a new car house, to cost about $70,000, according to reports. Baldwin & Pennington, Archs.——Lerch Bros. propose to erect a 7-story stone and iron warehouse, to cost about $60,000, according to reports.

LAUREL, MD.—Bids are asked until July 25 for constructing a 2-story brick school building to cost $10,000. R. W. Kerr, Secy. Com.; Albert Mason, Arch., Baltimore.

WASHINGTON, D. C.—Plans have been filed by R. H. Darby for a fireproof printing establishment at 14th St., near Pennsylvania Ave. T. F. Schneider, Arch.; R. N. Harper, for a fire-proof manufacturing building on C St., near 6th St.; Navy department, for a steel storage building at the navy yard. M. T. Endicott, Ch. Bureau Yards and Docks.

AKRON, O.—The following bids were received July 15 by the supervising architect, Washington, for the construction (except heating apparatus and electric wire conduits) of the post office building:

Michael Robett, Toledo, O.	$65,342	10	mos.
D. W. Thomas, Baltimore, Md.	51,875	8	"
Bennett & Rothrock, Williamsport, Pa.	61,503	10	"
Henry Shenk, Erie, Pa.	57,924	10	"
P. J. Carlin & Co., Brooklyn, N. Y.	62,000	10	"
Sam. C. Moore & Son, Kokomo, Ind.	48,892	10	"
Louis D. Beman, Cincinnati, O.	59,976	10	"
L. L. Leach & Son, Chicago, Ill.	54,797	10	"
Chas. Gindele Co., Chicago, Ill.	50,500	10	"
Bailey, Koerner & Co., Louisville, Ky	56,544	10	"
J. A. Reaugh & Son, Cleveland, O.	48,600	7	"
Miles & Bradt, Atlanta, Ga.	45,400	10	"
J. W. Myers & Co., Ashland, O.	43,819	9	"
Bennett, Michie & Co., Milwaukee, Wis.	47,490	11	"
McIlvain, Unkefer & Co., Pittsburg, Pa.	45,300	9	"

PORT CLINTON, O.—The county has voted to issue $40,000 of court house bonds.

CENTRALIA, ILL.—Bids are asked until Aug. 2 for the erection of a city hall and jail, according to reports. J. J. Bundy, City Atty.

CHICAGO, ILL.—Egan & Prindville, Archs., have completed plans for a convent to be erected between 49th and 50th Sts., and Evans and Liberty Aves., to cost $250,000. ——A permit has been granted for the erection of a $100,000 school building at 69th St. and Stewart Ave.——S. R. McCormick will construct three 6-story fireproof buildings on Michigan Ave., between Madison and Monroe Sts.——Mrs. Augusta Heberlein will erect an apartment building at 359 and 361 East Indiana St., at a cost of $40,000. Robt. S. Smith, Arch., Adams Express Building.

CHARLESTON, ILL.—The county supervisors have passed a resolution to build a new court house, at a cost of about $100,000.

DUNNING, ILL.—Bids are asked until July 25 for furnishing material and plans and installing a dry air system at the Dunning Institution. E. D. Northam, Supt. Pub. Service, Chicago.

STREATOR, ILL.—Plans are being prepared by Geo. P. Standuhar, Arch., Rock Island, for a 4-story office and club building, 146 ft. × 260 ft., for D. Heenan & Co., Streator; estimated cost, $130,000.

OSHKOSH, WIS.—Reports state that bids will soon be asked by the library commission for furnishing plans for a $40,000 library building. H. L. Battis, Chn.

RACINE, WIS.—The building belonging to the Racine Malleable & Wrought Iron Co. has been destroyed by fire, at a reported loss of $100,000.

MINNEAPOLIS, MINN.—Plans have been completed by E. P. Overmire, Arch., 1043 Lumber Exchange, for a 3-story apartment house, costing $50,000.

RUSH CITY, MINN.—F. C. Norlander, 1025 Bradley St., St. Paul, has been awarded a contract at $10,747 for constructing a school building. Archs., Omeyer & Thori, St. Paul.

CORNING, IA.—The mayor has appointed a committee to investigate the cost, etc., of constructing a new city hall.

DES MOINES, IA.—Bids are asked until Aug. 12 for constructing the west wing of the Iowa State Memorial Historical & Art Building, to cost $50,000, according to reports. Archs., Smith & Gutterson.

WATERLOO, IA.—Bids are asked until Aug. 2 for constructing a 3-story brick Y. M. C. A. Hall in this city. Archs., Murphy & Ralston; Chn. Com., A. N. Ferris.

BUTTE, MONT.—The school trustees received the following bids July 1 for constructing a school building: John F. Hogan, building complete, except plumbing and heating plant, $27,745; J. A. Riddell, complete, except heating plant, $28,337; Loss & Co., complete, $28,984; Laurence Burke, complete, $29,574, or stone and brick work only, $10,833; Thos. Laurier, complete, $29,545; C. C. Goddard & Co., complete, except heating plant, $34,743; Moses Benoit, complete, $28,673; Strunk & Maiette, stone foundation, cut stone and brick work, $12,550; I. Kruger, plumbing, $522; gas fitting, $235; steam heating, $3,550; Wm. C. Bryant, heating and ventilating, $3,830; Canney & Wright, plumbing and gas fitting, $620; Montana Hardwall Plastering Co., plastering, $1,757; Anaconda Mining Co., hardware department, steam heating $3,218; Echle Plumbing & Heating Co., steam heating, $3,893.

HELENA, MONT.—Press reports state as follows: The Supreme Court on July 5 declared valid the contract between Bell & Kent, formerly of Counicl Bluffs, Ia., but now of Helena, and the capitol building commission. Montana law requires capitol architects to be citizens of the state. Bell & Kent established their residence March 18, and the contract was let to them the following day. Action, it is said, was brought to break the contract by Butte architects. The decision will permit work on the $350,000 capitol to be commenced next fall.

LAWRENCE, KAN.—Bids are asked until July 25 for constructing a club-house for the Merchants' Athletic Building Association. F. W. Barteledes, Chn. Com.

KANSAS CITY, MO.—Root & Siemans have prepared plans for a warehouse, 42 × 120 ft., for the U. S. Water & Steam Supply Co.; estimated cost, $18,000. Gen. Mgr., H. S. Ferguson, 1211 W. 12th St.

ST. JOSEPH, MO.—P. P. Buddy, St. Joseph, has been awarded the contract for building a $100,000 live stock building at the St. Joseph Stockyards. The building will be of brick and four stories high. Work will begin at once, and will be completed Dec. 1.

HOUSTON, TEX.—The council has passed an ordinance to issue $60,000 in bonds for erecting school buildings.

YOAKUM, TEX.—The San Antonio & Arkansas Pass Ry. Co. will soon begin the construction of a new storage house to be 40 × 150 ft.

OAKLAND, CAL.—Plans for the proposed school of manual training were filed July 5 with board of education. They call for a building to cost $17,000. Nothing will be done in regard to the school at present on account of lack of funds.

SAN RAFAEL, CAL.—Competitive plans and specifications will be received by the high school board for erection of a high school building in San Rafael; building to cost not over $11,000. Thos. Hansen, Secy.

PETERSON, UTAH.—Bids are asked until Aug. 8 for erecting a 3-room brick school building at this place. Arch., R. C. Watkins, Provo and Ogden, Utah; Chn. Trustees, Martin Gaarder.

RICHFIELD, UTAH.—Bids are asked until Aug. 1 for erecting a county jail building. Arch., R. C. Watkins, Provo; S. F. Clark, Clk.

SALT LAKE CITY, UTAH.—It is stated that the contract for erecting an 8-room school building has been let to the Salt Lake Bldg. & Mfg. Co. at $15,536.

WATER-WORKS.

HAMPTON, N. H.—C. M. Lamprey, Clk. Hampton Water-Works Co., writes us that the directors will submit the question of building works to the town. The works will be built in another year by the town or by capitalists. The delay is caused by the difference of opinion as to who shall build the works, private parties or the town.

BOSTON, MASS.—Bids are asked until July 21 for laying 4,925 ft. of 16 and 450 ft. of 12-in. cast-iron water pipe in Watertown and Belmont. Wm. N. Davenport, Secy. Metropolitan Water Bd., 3 Mount Vernon St.

HOLDEN, MASS.—Chas. E. Parker writes us that the town has not yet voted to secure a water supply from Lake Murchepange, but a gain in the number of votes for it has been made at each trial. A special town meeting will probably be called soon when it is likely another vote will be taken.

TAUNTON, MASS.—The water commissioners are reported as considering the question of making improvements to the works and of adding a new 8,000,000-gallon engine; estimated cost, $60,000. Supt., Geo. F. Chace.

ALBANY, N. Y.—Bids are asked until Aug. 2 for furnishing and installing a pumping station and intake for the filtration plant, as stated in our advertising columns. Ch. Engr., Allen Hazen, St. Paul Bldg., New York; Supt., Geo. I. Bailey.

CATTARAUGUS, N. Y.—Bids are asked until Aug. 4 for furnishing three-fourths of a mile of 4-in. pipe. Frank S. Oakes, Village Pres., writes us that $7,000 4% 20-year bonds are to be issued for extending the works for a distance of four miles for an increased water supply. Only about three-fourths of a mile of new 4-in. pipe will be required. Engr., W. J. White, Buffalo.

FORESTVILLE, N. Y.—The Forestville Water Co. has been incorporated with a capital stock of $10,000 by Howard M. Fordham, Buffalo, N. Y., and Albert Herrig and Richard J. Monahan, Forestville. There is a small plant here that is owned by the town.

JAMESTOWN, N. Y.—C. B. Jones, Cy. Clk., writes us that no steps have yet been taken toward securing new works.

MAYVILLE, N. Y.—This place voted July 2 to extend the works, according to reports. E. Delavan Smalley, Engr., Syracuse, N. Y., may give information.

NEW YORK, N. Y.—Bids are asked by the department of water supply, 150 Nassau St., until July 28, for furnishing and laying water mains in Fordham Road across the Harlem River ship canal and in 109th St., etc.

NORWOOD, N. Y.—Watson B. Berry, Pres. Norwood Water Co., Massena, N. Y., writes us that bids will be asked about Sept. 1 for furnishing and constructing five miles of cast-iron water pipe, hydrants, standpipe, etc., for the proposed works. A filtration plant will also be put in. The source of supply will be the Racquette River.

NYACK, N. Y.—Jas. S. Haring, Engr., writes us that the private works known as the Onderdonk Water-Works, owned by Mrs. Rachel C. Odell, is only a small plant, having 1¼ and 1½-in. pipe and some 3 and 4-in. cast-iron pipe. It is a gravity plant from springs at an elevation of 175 ft. The town will vote on the question of issuing $15,000 in bonds for the purchase of the same.

TONAWANDA, N. Y.—Bids are asked until July 25 for taking up and relaying the 12-in. water main across the Niagara River, etc. J. H. Vickers, Clk.

WHITE PLAINS, N. Y.—Bids are asked until July 25 for the purchase of $130,000 of 4% water bonds. Howard E. Foster, Treas.

CAMDEN, N. J.—Bids are asked by the water committee until July 26 for furnishing water meters to be placed in factories, mills and the railway yards.

FREEPORT, PA.—The South Buffalo Water Co. has been incorporated to supply water in South Buffalo township, Armstrong county; capital stock, $5,000; incorporators, Frank Maxler, Treas.; D. S. Wallace, J. B. Patterson, J. E. Williams, J. T. McCulloch and John A. Singer, Freeport.

OIL CITY, PA.—The following bids were received June 15 for furnishing a pump and four 50-HP. gas engines, as advertised in Engineering News; all the bids have been rejected; A. M. Breckinridge, Clk.:

Gas Engines:

Western Gas Const'n Co., Fort Wayne, Ind.	$8,350
Otto Gas Engine Works, Philadelphia, Pa.	6,400
Joseph Reid, Oil City, Pa.	2,590
National Meter Co., 86 Chambers St., New York	8,955
St. Mary's Machine Co., St. Mary's O.	3,200
White & Middleton Gas Eng. Co., Baltimore, Md.	7,300
Roth Gas Engine Co., Indianapolis, Ind.	5,2[illegible]0
Loretz Bros., New York	9,500
Erie Gas Engine Co., Erie, Pa.	4,400

Pumps: Oil City Boiler Works, Oil City, Pa.—$20,737 for one 300,000-gallon and two 1,500,000-gallon Gould Power Pumps, or $27,362 for same capacity as above with Snow Power Pumps; Snow Steam Pump Works, Buffalo, N. Y.—$38,610 for vertical triple expansion pumping engine, or $28,390 for vertical cross-compound pumping engine; Nordberg Mfg. Co., Milwaukee, Wis., $30,750 for vertical cross-compound pumping engine; Loretz & Son, 126 Liberty St., New York—$21,000 for vertical triple expansion pumping engine, or $16,000 for three power pumps as above.

LATROBE, PA.—The Latrobe Water Co. has let the contracts as follows for its proposed works: Pumping engines, Henry R. Worthington, New York; boilers, the Erie City Boiler Works, Erie, Pa.; pipe laying, H. F. Stark, Greensburg, Pa. The contracts for building the pumping station and reservoir will be let later. The pumps will have a capacity of 3,000,000 gallons. There will be three miles of 6 to 16-in. pipe and a reservoir of 9,000,000 gallons capacity. Engrs., Wilkins & Davison, Westinghouse Bldg., Pittsburg.

NAZARETH, PA.—Surveys have again been made for the proposed increased water supply for the works of the Nazareth Water Co. John W. Trumbower and C. Edward Michael may be addressed. Frank Kunkel, Borough Surv.

PHILADELPHIA, PA.—Bids are asked until July 26 for building and for furnishing boilers and 48-in. cast-iron water pipe. T. M. Thompson, Dir. Dept. Pub. Wks.——Plans are reported as being prepared for a reservoir on Georges Hill for an increased water supply for West Philadelphia; estimated cost, $500,000.

WARREN, PA.—Wm. O'Neil, Chn. Com., writes us that this city voted July 12 to issue $50,000 in bonds for constructing city works. About 90% of the vote cast was in favor of the works. A report dated July 15 states that Judge Lindsey has granted a temporary injunction, asked for by the Warren Water Co., restraining the city from building the proposed works.

CUMBERLAND, MD.—Mayor Kean has recommended that the council appropriate $2,000 for use by the committee for investigating the advisability of securing a better water supply.

MARTINSBURG, W. VA.—Bids are asked by the water board for furnishing and installing a compound condensing duplex pump of 2,500,000 gallons capacity.

PARKERSBURG, W. VA.—We are informed that the following bids were received July 11 for furnishing and laying 36 and 14-in. submerged water pipe, as advertised in Engineering News; the contract for the 36-in. pipe was let to Thos. H. Regan & Son, Philadelphia, at $12,601, as noted under Contract Prices; the bids for the 14-in. pipe were rejected: A. G. Hallock & Co., Wheeling, W. Va., $15,700 and $1,400, respectively, for 36 and 14-in. pipe, and Jos. Cavanaugh, Parkersburg, $15,800 and $1,450, respectively.

SMITH'S GROVE, KY.—Bids are asked by J. R. Kirby, Farmers' Bank, for furnishing the material and for constructing works, according to reports. There will be a standpipe 12 × 40 ft.

CAMDEN, O.—It is stated that this place is considering the question of building works.

LANCASTER, O.—It is stated that Ingham & Neeb, Lancaster, have been awarded the contract for furnishing the material and for constructing the works and sewerage system for the Boys' Industrial School as follows: Sewerage system, $5,861; sewage purification works, $9,029; pumping station for water-works, $8,827; water-works complete, $10,780; boiler house for steam plant, $7,466; stack for boiler house, $2,300. Addyston Pipe & Steel Co., Cincinnati, O., secured the contract for the cast-iron pipe and specials at $1,963. The contract for the steam plant was not let. C. D. Hilles, Secy. Bd. Trustees.

PAW PAW, MICH.—We are informed that this place voted July 11 to issue $18,000 in bonds for works. The council will be ready for bids about Aug. 15. Engr., Geo. S. Pierson, Kalamazoo, Mich.; Clk., Wm. H. Mason.

YALE, MICH.—Bids are asked until July 26 for constructing the proposed works, as advertised in Engineering News July 7. (Postponement from July 19.) E. F. Fead, Village Clk.

MINNEAPOLIS, MINN.—Bids are asked until Aug. 26 for furnishing and installing one or two 10,000,000-gallon pumping engines, as stated in our advertising columns. F. W. Cappelen, Cy. Engr.; L. A. Lydiard, Cy. Clk.

MORRIS, MINN.—We are informed that the following bids were received July 9 for furnishing the materials and for constructing works. Engrs., Iowa Engineering Co., Clinton, Ia.:

W. I. Gray & Co., Minneapolis, Minn.	$32,645
Fairbanks, Morse & Co., St. Paul, Minn.	29,000
Dubuque Construction Co., Dubuque (accepted)	26,420
P. Doherty, St. Paul	29,893

DES MOINES, IA.—Geo. M. King, Cy. Engr., writes us that the council and the Des Moines Water-Works Co. have reached an agreement. The council has offered the company $850,000 for its works. The company has accepted the same. The question will be submitted to a vote of the people Aug. 29.

GILMORE CITY, IA.—This city is reported to have voted against issuing bonds for works.

GAYLORD, KAN.—The question of putting in a small plant for fire protection is being considered, according to reports. W. H. Haskell may be addressed.

BEATRICE, NEB.—Tests are to be made with a view to securing an increased water supply. W. A. Lapworth, Ch. Engr.

BATESVILLE, ARK.—We are informed that the following bids were received July 14 for furnishing and constructing works and an electric plant; Owen Ford, Engr., Security Bldg., St. Louis, Mo.:

G. Jaeger, Rich Hill, Mo.*	$23,985
Reese Bros., Fayetteville, Ark.	25,750
Brown Machinery Co., Little Rock, Ark.	25,520

*Awarded contract at $24,720; a number of additions making the extra cost.

CORSICANA, TEX.—Press reports state that the receiver for the Corsicana Water Co. is having surveys made south of the city preparatory to the beginning of improvements that will cost about $25,000. The improvements to be made in the plant will consist of an increase of the water shed that supplies the water and an additional reservoir that will in connection with the present storage facilities hold water sufficient for a city twice the size of Corsicana at present.

McKINNEY, TEX.—J. M. Pearson, Mayor, writes us that it is expected to offer a contract for erecting works in about a month or so; estimated cost, $18,000.

WARD, COLO.—D. J. McCanne, Des. Engr., 1700 17th St., Denver, Colo., writes us that the proposed water supply will be furnished by gravity. A reservoir of three acres will be built. There will be required 3,500 ft. of 12-in. riveted steel pipe, 5,000 ft. of 6 and 4-in. pipe, 15 hydrants, 12 valves, 10 boxes, 2,600 lbs. converse hub specials, etc. Bids for the purchase of $8,000 of bonds will be asked first.

SEATTLE, WASH.—The council has voted seven to six in favor of asking for new bids for furnishing and constructing the water tower for the Cedar River supply. The itemized bids were given in our issue of last week. Frank Oleson, Secy. Bd. Pub. Wks.

SACRAMENTO, CAL.—The board of education is considering the question of placing water filters in the public schools.

SONOMA CITY, CAL.—Fred. T. Duhring, Pres. Bd. City Trustees, writes us that the question of building works is still in abeyance while the committee is making investigations on new lines. The matter will not come to a vote before Oct. 25.

IDAHO FALLS, IDAHO.—It is stated that this place will vote Aug. 9 on the question of purchasing the works and light plant of the Eagle Rock Water-Works Co. for $25,000. Geo. Chapin, Chn. Com.

AYLMER, ONT.—The council is reported to have been petitioned to purchase the works for $35,000. Mayor Woods and Councilman Wright may be addressed.

OTTAWA, ONT.—Louis H. Tache, Montreal, Que., is reported to have been awarded the contract for furnishing and constructing the works for Gatineau Point at $30,000. Engr., Ernest Belanger, Montreal, Que.

SEWERAGE.

BREWER, ME.—Bids are asked until July 21 for constructing sewers in several streets. Engr., P. H. Coombs, 11 Exchange Block, Bangor, Me.; Chn. Com., C. C. Worth.——Isaac Lunt, Bangor, has been awarded the contract for constructing sewers in 12 streets at about $7,375.

SPRINGFIELD, MASS.—The harbor and land commissioners have granted this city the right to build a submerged outlet sewer in the Connecticut River.——The committee has visited Worcester, Providence and other cities to study methods for the disposal of sewage, with a view to putting in a system in the Highlands. O. D. Allyn and Gilbert Potvin, Jr., are on the committee.

EAST HARTFORD, CONN.—Wm. H. Olmstead, Surv., is preparing plans, etc., for sewers. It is probable that only a brick sewer will be built this year.

WALLINGFORD, CONN.—Bids are asked until Aug. 2 for furnishing the materials and for constructing 6,600 ft. of 30-in. pipe sewer, as stated in our advertising columns. The committee consists of John E. Downs, Chas. Tooth, Sr., and Wm. I. Todd.

LANCASTER, N. Y.—Allan Gardner, Jamestown, N. Y., has been engaged to prepare plans for a system for this place. Geo. Bingham, Chn. Com.

KINGSTON, N. Y.—J. T. Cummings, Cy. Clk., writes us that it is proposed to construct a 5-ft. brick trunk sewer. It will not be built this year. Other sewers are also proposed. W. Klingberg, Cy. Engr.

NEW YORK, N. Y.—Bids are asked by the commissioners of parks, the Arsenal, Central Park, until July 28 for constructing sewers in Central Park, etc.

ELIZABETH, N. J.—Bids are asked until Aug. 1 for constructing 1,100 ft. of 24 and 12-in. pipe sewers, etc. N. K. Thompson, St. Comr.

FLEMINGTON, N. J.—Bids are asked until July 30 for furnishing the material and for constructing a system and a sewage disposal plant, as described in our advertising columns. Engrs., Waring, Chapman & Farquhar, 874 Broadway, New York; Clk., John H. Shrope.

NEWARK, N. J.—At a conference of officials from Newark, South Orange, Vailsburg and Irvington in regard to the proposed joint sewer, it was decided to ask West Orange to join and then create a commission of five to make surveys, etc. In order to drain Irvington, Vailsburg and that part of Newark which may connect with the proposed sewer, a branch will have to be constructed. This will join the South Orange or trunk sewer at Salem. The cost of the construction of the entire sewer is estimated at $160,000. Councilman Sinclair, South Orange, may be addressed. Ernest Adam, Cy. Engr., Newark.

PATERSON, N. J.—It is proposed to construct 1,200 ft. of 15 and 12-in. pipe sewer. Thos. McLean, Cy. St. Comr.

AVALON, PA.—J. A. Ranson, Sharpsburg, Pa., has been awarded the contract for building the sewers for this place at $25,000, according to reports.

BRADDOCK, PA.—Bids are asked until July 28 for constructing sewers, paving, etc., in Kirkpatrick Ave., North Braddock. Engr., S. A. Taylor, North Braddock, or 339 Fifth Ave., Pittsburg.

OIL CITY, PA.—It is proposed to construct sewers in several streets.

McKEE'S ROCKS, PA.—Bids are asked until July 25 for constructing 3,500 ft. of 72 and 60-in. brick sewers. R. F. Hunter, Borough Engr.; C. K. Barnhardt, Chn. Com.

WASHINGTON, D. C.—The district commissioners have ordered the construction of a 24, 21 and 18-in. pipe sewer in 16th St., from Florida Ave. to Morris St.; estimated cost, $2,875.

WAYCROSS, GA.—R. P. Bird, Clk. Council, writes us that this city voted July 9 against issuing bonds for a system. Another election will be called in January.

LANCASTER, O.—It is stated that the contract for constructing the system for the Boys' Industrial School has been let to Ingham & Neeb, Lancaster, at $5,861; sewage disposal works at $9,029. C. D. Hillis, Secy. Trustees.

TOLEDO, O.—Bids are asked until Aug. 8 for constructing a 24-in. brick sewer and 15 and 10-in. pipe sewers in several streets. L. P. Harris, Cy. Clk.——The committee has rejected the bids received recently for a sewer in Payne Ave.; to cost about $20,000.

AURORA, IND.—Bids are asked until July 30 for constructing sewers in several streets. J. J. Backman, Cy. Clk.

HUNTINGTON, IND.—Bids are asked until July 26 for constructing a 34 × 51 and a 30 × 45-in. brick and 20 to 17-in. pipe sewers in several streets. Frank Guthrie, Cy. Engr.

PORT HURON, MICH.—F. F. Rogers, Cy. Engr., writes us that W. F. Ernst has been awarded the contract for 1,610 ft. of 24 to 8-in. pipe sewer in 14th St., at $2,275.

PORTLAND, MICH.—It is proposed to construct sewers in several streets at a cost of about $3,700. Engr., D. C. Crawford.

CHICAGO, ILL.—Bids are asked until July 25 for constructing sewers in a number of streets, etc. L. E. McGann, Pres. Bd. Local Improvements. J. S. Sheahan, Secy.

EAST ST. LOUIS, ILL.—Bids are asked until July 21 for constructing about 45,000 ft. of 30 to 6-in. pipe sewers, 335,000 brick in manholes, etc. M. M. Stephens, Mayor.

MILWAUKEE, WIS.—Bids are asked by the board for building the proposed sewer tunnel. Geo. H. Benzenberg, Cy. Engr. and Chn. Comrs. Pub. Wks.

DES MOINES, IA.—Geo. M. King, Cy. Engr., writes us that the council has passed a resolution of necessity for constructing 12-in. pipe sewers in Harrison St., from 14th to 13th Sts. and in 13th St., from Harrison to College Ave. and in College Ave., from 13th to 12th St.——According to local papers other sewers are also proposed.

NEW ULM, MINN.—Bids are asked until July 25 for constructing 24 and 18-in. pipe sewers in certain streets. Louis Schilling, Cy. Clk.

OMAHA, NEB.—Bids are asked until July 29 for constructing sewers in district No. 230. Andrew Rosewater, Chn. Bd. Pub. Wks.; Wm. Coburn, Secy.

ANACONDA, MONT.—The council has voted to construct pipe sewers in six streets at a cost of about $8,000. I. O'Leary, Cy. Clk.

TOPEKA, KAN.—The council has voted to build a sewer in Ward No. 1. S. S. McFadden, Cy. Clk.

KANSAS CITY, MO.—The question of building a system for Westport, recently annexed to this city, is being considered; estimated cost, $50,000. If an intercepting sewer is built to the river the cost will be about $300,000. The question of sewers for Mellier Place is also being considered.

GAINESVILLE, TEX.—It is reported that this place has let the contract for building a system here. The fire limits will be supplied first, after which the other parts of the city will be furnished.

DENVER, COLO.—Chief Engineer Lowrie, of the board of public works, is preparing plans for a system of storm sewers for the eastern portion of the city; estimated cost, $750,000.

OAKLAND, CAL.—It has been voted to construct sewers in several streets. J. W. Tompkins, Cy. Clk.

SALINAS, CAL.—Bids are asked until Aug. 1 for furnishing the material and for constructing a sewerage system. J. J. Kelly, Cy. Clk.

LONDON, ONT.—Bids are asked until July 28 for furnishing and laying about 3,300 ft. of 30-in. cast-iron sewer pipe and 300 ft. of 20-in. steel pipe, together with the construction of the syphon chambers, etc. Consult. Engr., Willis Chipman, Toronto; Cy. Engr., Ormsby Graydon; Chn. Com., N. Cooper.

KASLO, B. C.—G. O. Buchanan, ex-alderman, writes us that plans for the proposed system are pending decision of the provincial board of health as to the discharge into Kootenay Lake.

GARBAGE DISPOSAL—STREET CLEANING

BUFFALO, N. Y.—Bids are asked until July 28 for cleaning the paved streets for three or five years, from Aug. 1. R. G. Parsons, Secy. Bd. Pub. Wks.

EAST ORANGE, N. J.—Chas. F. Finan submitted the lowest bid July 11 at $2,900 a year for the scavenger work in this township.

BALTIMORE, MD.—It is proposed to clean the sewers of the city soon at a cost of about $100,000. Street Cleaning Commissioner Bye may be addressed.

WHEELING, W. VA.—A local paper states that the board of health has directed A. L. White, Cy. Engr., to visit eastern cities to study methods of garbage disposal plants. It is estimated that a new plant can be built in this city for $2,500.

NEWPORT, KY.—This city wants estimates, etc., for a garbage disposal plant, as stated in our advertising columns. W. L. Glazier, Cy. Engr.

LOS ANGELES, CAL.—Bids will soon be asked by the council for street sweeping. The present contract expires Nov. 20. The city is paying $5.85 a lin. mile for sweeping the paved streets. It is proposed to have the down-town streets swept next year by hand.

STREETS AND ROADS.

BROOKLINE, MASS.—A. H. French, Cy. Engr., informs us that no action besides making plans and estimates has been taken in regard to the improvement of Boylston St.

MERIDEN, CONN.—Reports state that the council has voted to issue about $200,000 in bonds for paving.

SUFFIELD, CONN.—Bids are asked until Aug. 1 for grading and macadamizing in North St. E. Halladay, First Selectman

BROOKLYN, N. Y.—Bids are asked until Aug. 2 for repairing and maintaining asphalt paving in certain streets and for furnishing broken stone and limestone screenings. The total length is about 16 miles. No bids were received for this work when bids were to be opened recently. It is thought that the method of payment was the cause of no bids being received. J. P. Keating, Comr. Highways, 150 Nassau St., Manhattan.

BUFFALO, N. Y.—Bids are asked until July 27 for paving Clinton St., from Lewis St. to Babcock St. R. G. Parsons, Secy. Bd. Pub. Wks.——Bids are asked until Aug. 1 for paving Porter Ave. with asphalt from Fourth St. to the bridge. G. H. Selkirk, Secy. Park Comrs.

CORTLAND, N. Y.—Bids are asked until July 25 for furnishing the materials and for 22,000 sq. yds. of asphalt and 6,400 sq. yds. of Medina stone or brick paving, as described in our advertising columns. Engr., H. C. Allen, Kirk Block, Syracuse, N. Y.; Clk., W. C. Crombie.

MOUNT VERNON, N. Y.—Bids are asked until July 25 for grading and macadamizing portions of South Columbus Ave. Wm. N. Hoyt, Cy. Clk.

NEWBURGH, N. Y.—The following are the lowest bids received July 1 for paving in South Liberty St.: M. J. Dwyer, granite blocks. $17,285; Hastings Co., New York, asphalt, $25,687; W. R. Johnson, Catskill, brick, $19,760. D. J. Coutant, Clk.

NEW ROCHELLE, N. Y.—The street committee has filed estimates amounting to $125,000 for paving and macadamizing.

NEW YORK, N. Y.—Bids are asked until Aug. 2 for furnishing 100,000 gallons of No. 6 paving cement. J. P. Keating, Comr. Highways, 150 Nassau St.

NORWICH, N. Y.—Bids are asked until July 25 for paving East Main St. and West Main St. with brick, as described in our advertising columns. J. B. Turner, Pres. Bd. Trustees.

ROCHESTER, N. Y.—Contracts were awarded July 8 to the Rochester Vulcanite Paving Co. for asphalt paving in Parsells Ave., at $29,514, and F. A. Brotsch, for brick paving in Spencer St., at $9,965. E. A. Fisher, Cy. Engr.

RIDGEFIELD, N. J.—C. B. Wilson, Clk., informs us that the following bids were received July 12 for constructing a macadam road; advertised in Engineering News, June 23 and 30: Robt. J. Emmer, Highwood Park, complete contract, $8,175; Joseph Murphy, 308 Charles St., West Hoboken, $5,940; D. L. Barrett, Englewood, $7,800; J. A. Winterburn, Edgewater, $4,975; Palisade Construction Co., 1 Montgomery St., Jersey City, $7,976; Cannon & Marronne, $8,400; John Collins, 536 Palisade Ave., Jersey City, curbing, 40 cts. ft.; Telford, 50 cts. sq. yd.; crushed stone, $2 cu. yd.; Brook paving, 12 cts. sq. ft.; excavating, 30 cts. ft.; rock cutting, $2; stone work, 20 cts. ft.; Belgian blocks, $1.50 yd.; mountain dressed stone, 85 cts. yd.; basins, $1.50, complete.

MALVERN, PA.—Bids are asked until July 25 for grading Monument Ave., from Warren Ave. to Sugartown Road. W. G. Watson, Secy. Com.

MEADVILLE, PA.—Bids are asked until July 27 for brick paving, as described in our advertising columns. W. A. Doane, Cy. Engr.; D. T. McKay, Jr., Cy. Clk.

McKEE'S ROCKS, PA.—Bids are asked until July 25 for about 14,000 sq. yds. of asphalt block or brick paving and 10,400 lin. ft. of curbing in Chartiers St. and Bell Ave. R. F. Hunter, Borough Engr.

NANTICOKE, PA.—An ordinance has been passed by the council to pave portions of Main and Market Sts. with brick. Wm. T. Mahon, Pres.; W. J. Burnett, Burgess.

PITTSBURG, PA.—Bids will soon be asked for the construction of five roads, at a cost of about $200,000. Fred. W. Patterson, County Road Engr.

SHAMOKIN, PA.—The council will give a hearing Aug. 23 to vote on the question of borrowing $65,000 for paving.

MANNINGTON, W. VA.—Henry Robrecht, Wheeling, has been awarded a contract for paving with the McMahon, Porter & Co. repressed brick, to cost about $80,000.

BIRMINGHAM, ALA.—A petition has been presented to the county commissioners by the Commercial Club for the construction of a boulevard on the north side of Red Mountain.

BLOUNTVILLE, TENN.—Bids are asked for macadamizing a road between Blountville and Bristol, to cost $3,000. J. H. Cole, Chn. County Comrs.

ASHLAND, O.—Bids are asked until July 30 for the purchase of $60,000 of 5% street and improvement bonds. E. B. Westover, Cy. Clk.

BEREA, O.—Bids are asked until Aug. 1 for the purchase of $3,500 of 5% street bonds. E. S. Loomis, Village Clk.

CANTON, O.—Bids are asked until July 31 for the purchase of $4,834 of 5% street bonds. L. N. Ley, Clk.

FREMONT, O.—Bids are asked until Aug. 15 for paving Hayes Ave. with brick from Front St. to Buckland Ave., and macadamizing and grading a portion of Napoleon St. R. J. Christy, Chn. Improvement Com.

LIMA, O.—Bids are asked until Aug. 8 for the purchase of $73,200 of 5% street improvement bonds. C. E. Lynch, Cy. Clk.

MALTA, O.—Bids are asked by the city clerk until Aug. 20 for the purchase of $10,000 of 5% street bonds.

RAVENNA, O.—An ordinance has been passed to pave Main St. with brick. Work will begin at once.

TOLEDO, O.—Bids are asked until Aug. 8 for furnishing material and paving an alley between St. Clair St. and Superior St. L. P. Harris. Cy. Clk.

LA FAYETTE, IND.—Bids are asked until Aug. 8 for improving portions of seven streets. Thos. W. Burt, Cy. Clk.——A contract will be let in August for constructing about two miles of asphalt pavement; estimated cost, $100,000; and for nearly 20 miles of cement sidewalk; estimated cost, $100,000.

RICHMOND, IND.—Bids are asked until July 29 for grading and paving one alley. J. H. Winder, Clk. Bd.

EAST ST. LOUIS, ILL.—Bids are asked until July 22 for grading, brick paving and sewering a portion of Main and Fourth Sts. M. M. Stephens, Mayor.

KEWANEE, ILL.—Bids are asked until Aug. 2 for brick paving, as stated in our advertising columns. J. C. Quade, Cy. Engr.

WATERTOWN, WIS.—The council has voted to pave Main St. for five blocks.

DES MOINES, IA.—Geo. M. King, Cy. Engr., writes us that the council has passed an ordinance to construct 10,000 sq. yds. of brick pavement.

NEW ULM, MINN.—Bids are asked until July 25 for grading, graveling, etc. Louis Schilling, Cy. Clk.

FARGO, N. DAK.—Reports state that the council is arranging to pave about five miles of streets this summer.

OMAHA, NEB.—Bids are asked until Aug. 15 for about 35,000 cu. yds. of grading D. M. Haverly, County Clk.

OMAHA, NEB.—Bids are asked until July 29 for brick, asphalt or stone paving in 32d Ave., from Davenport St. to Farnham St. Wm. Coburn, Secy. Bd. Pub. Wks.

JEFFERSON CITY, MO.—Bids are asked by the city treasurer until July 25 for the purchase of $6,000 of 5% street bonds.

HOUSTON, TEX.—The ordinance to issue $100,000 in bonds for street improvements has been passed. J. A. Miller, Cy. Engr.

WINDSOR, ONT.—The board of public works has received an estimate of $25,750 for the paving of Second Ave. with asphalt.

MANUFACTURING PLANTS.

ELIZABETH, N. J.—The car repair shops at Elizabethport, belonging to the Central Ry. of N. J., were destroyed by fire July 16, causing a reported loss of about $200,000.

PHILADELPHIA, PA.—The 5-story mill building at American and Diamond Sts., was destroyed by fire July 10, causing a reported loss of $100,000. The building was occupied by Oliver Lupton & Co., Philadelphia Linen Co., Champion Machine Co. and the Franklin Silk Mills Co.

ROCK HILL, S. C.—Wm. O. Webber, Exchange Bldg., Boston, Mass., is reported to have been engaged to prepare plans for enlarging the plant of the Rock Hill Cotton Factory Co. The plant, which has now 7,904 spindles and 192 looms, will be extended to accommodate 10,000 spindles. The improvements will cost about $200,000.

MONTGOMERY, ALA.—The Montgomery Compress Co., it is stated, has let the contracts for building and furnishing its plant; to cost about $30,000. Pres., Jos. P. Ferrell; Secy. and Treas., C. L. Stickney.

LOUISVILLE, KY.—L. K. Ferguson, of the Globe Refining Co., writes us that the contract has been let for the building for the plant. The contracts for the storage tanks, boilers and electrical equipment are to be let as soon as the plans are completed. The company is to manufacture seed oils, etc. Arch., John Chambers, Room 39, American National Bank Bldg., Louisville.

LOUISVILLE, KY.—The building occupied by James Clark, Jr., & Co., electrical supplies, on Main St., belonging to H. Weissinger, was destroyed by fire, at a reported loss of $50,000.

CAMBRIDGE, O.—It is reported that the West End Rolling Mill Co. will erect a building to be used for trimming. It will be 30 × 60 ft.

NEW CASTLE, IND.—Press reports state that the New Castle Bridge Works will be extended by the construction of a few new buildings. Runyon & Mouch own the works.

KALAMAZOO, MICH.—The Clark Engine & Boiler Co. will build an additional machine shop at once, according to reports. It will be 40 × 100 ft.

MOLINE, ILL.—Williams, White & Co., it is stated, are arranging to build a new foundry for its plant to be 60 × 140 ft. A 15-ton electric crane, etc., will be required.

LA CROSSE, WIS.—A fire on July 17 is reported to have destroyed the sash and door factory of Segelke-Kohlhaus Co. and the lumber yards of the John Paul Lumber Co., causing a loss of about $150,000.

RACINE, WIS.—The 3-story structure of the Racine Malleable & Wrought Iron Co. was destroyed by fire July 13, resulting in a loss of $100,000 and of probably eight lives.

STEVENS POINT, WIS.—The mill belonging to the Wisconsin River Pulp & Paper Co. has been destroyed by fire, causing a reported loss of about $175,000. It is stated that a new plant will be built.

ST. PAUL, MINN.—Plans are reported to have been prepared for enlarging the shops of the Great Northern Ry. in this city. Work on the shops will begin in about two months.

COFFEYVILLE, KAN.—It is proposed by the Coffeyville Vitrified Brick Co. to build a plant at Cherryvale to have a capacity of about 100,000 brick a day. Besides the machinery there will be required about 200 iron cars, etc.

KANSAS CITY, MO.—Zachary T. Davis, Arch., Chicago, Ill., is preparing plans for the erection of a packing plant for Schwartzchild & Sulzberger, to cost $600,000, according to reports.

ST. JOSEPH, MO.—It is stated that the Jamieson-Combe Iron Co. proposes to build a machine shop, 50 × 80 ft., on ground in this city it recently purchased.

ELGIN, ORE.—It is reported that the capitalists building a beet factory here will send a representative to Walla Walla, Wash., next week. They will propose to the citizens of that city that for a subsidy of $100,000 they will build a beet sugar plant to cost about $400,000.

OTTAWA, ONT.—Reports state that the New York & Ottawa Ry. Co. will erect work shops for the construction of its new road.

CHIHUAHUA, MEX.—It is reported that the Wellman Seaver Engineering Co., New England Bldg., Cincinnati, O., has entered into a contract for the construction of a steel plant, at this place.

GAS PLANTS.

McPHERSON, KAN.—A. Bass, Cy. Engr., informs us that the city is in litigation with the Water & Light Co. and if a compromise is not made a new company will be organized to construct a water and gas plant.

NEW COMPANIES.—Chester Oil Co., Pittsburg, Pa.; $1,000,000, with $1,000 paid in; to bore for oil and gas; F. M. Lowry, W. S. Watson, Wm. Lyons, Jr., H. G. Wasson, J. P. Cappeau, Pittsburg.

Knickerbocker Gas Co., 419 Market St., Camden, N. J.; $500,000 with $1,000 paid in; to manufacture and construct plants, machinery, etc., and produce gas for light, heat and power; Wilson Waddinghand, Edward P. Baker, Geo. H. B. Martin, 419 Market St., Camden.

Mutual Gas Co., Denver, Colo.; $100,000; J. A. Cooper, T. F. Dunaway, Charles Wheeler, F. A. Bailey and William Ridley.

Milford Gas Co., Milford, Pa.; $10,000; to manufacture and sell acetylene gas in the borough of Milford; Thomas Armstrong, Joseph J. Hart, James S. Gale, Harry T. Baker, Milford, Pa.; Lancelot W. Armstrong, New York.

MISCELLANEOUS CONTRACTS.

PARK WORK.—Spokane, Wash.—An ordinance is before the council for an appropriation of $10,000 for improving the parks.

TELEPHONE PLANT.—Terre Haute, Ind.—Bids are asked by the People's Telephone Co., according to reports, for the construction of a plant.

TELEPHONE FRANCHISE.—Lexington, Ky.—The council has granted a 20-year franchise to the East Tennessee Telephone Co. at an annual rental of $1,200.

RIVER WORK.—Buffalo, N. Y.—City Engineer Bardol has completed the plans for improving Buffalo River by widening and dredging, and bids will be asked.

DREDGING.—Brooklyn, N. Y.—Bids are asked until July 27 for dredging Gowanus Canal, from Douglas St. to Union St. James Kane, Comr. Sewers, Municipal Bldg.

RETAINING WALL.—Cincinnati, O.—Bids are asked until July 25 for constructing a retaining wall, between Russell and Ida Sts. A. P. Butterfield, Clk. Bd. Cy. Affairs.

PINE TIMBER.—New York, N. Y.—Bids are asked until July 29 for furnishing about 1,862,455 ft. B. M. of sawed yellow pine timber. J. S. Crain, Comr. Docks, Pier A.

WHARF.—Point Wilson, Wash.—Bids are asked until Aug. 2 for building a wharf at Point Wilson, Wash. Capt. Harry Taylor, U. S. Engr., Burke Bldg., Seattle, Wash.

TELEPHONE SYSTEM.—Mankato, Minn.—Bids are asked by the Mankato Citizens' Telephone Co. until July 29 for constructing a telephone system, according to reports.

STERILIZING APPARATUS.—Dunning, Ill—Bids are asked until July 25 for installing a sterilizing apparatus at the Dunning Institution. E. D. Northam, Supt. Pub. Service, Chicago.

MONUMENT.—Olean, N. Y.—The G. A. R. is contemplating the building of a soldiers memorial fountain and monument to cost about $5,000. Henry Gale, Commander, may be addressed.

STONE COPING, FLAG, ETC.—Brooklyn, N. Y.—Bids are asked until July 28 for furnishing stone coping, curb and flag. Geo. C. Clausen, Chn. Park Comrs., Arsenal Bldg., Central Park.

TELEPHONE SYSTEM.—Birmingham, Ala.—The council has granted permission to the American Telephone & Telegraph Co. to construct and operate a telegraph and telephone system. F. V. Evans, Mayor.

GRADING.—St. Louis, Mo.—Bids were received until July 20 for about 150,000 cu. yds. of grading in the district north and south of Russell Ave. Address Pitzman Co., Survs. and Engrs., 615 Chestnut St.

PARKS.—Indianapolis, Ind.—The council has passed an ordinance authorizing the expenditure of $235,215 for the purchase of land and laying out parks. Messrs. McGrew, Merrick and Crall, Pub. Improvement Com.

TELEPHONE CABLES.—Buffalo, N. Y.—The National Conduit & Cable Co., New York, has been awarded a contract at $3,515 to furnish saturated cable for constructing a telephone system for the police department.

TRAVELING CRANES.—Chicago, Ill.—Plans are asked until Aug. 30 for the erection of electric traveling cranes for the new pumping stations at Springfield Ave. and at Central Park Ave. L. E. McGann, Comr. Pub. Wks.

FURNITURE.—Binghamton, N. Y.—Bids are asked until Aug. 9 for furnishing desks, tables, filing cases, chairs and other necessary furniture for the new city hall, as stated in our advertising columns. Burr W. Mosher, Cy. Clk.

TELEPHONE SYSTEM.—Baltimore, Md.—J. A. Shriever, Pres. Baltimore & Blaire Telephone Co., has applied to the county commissioners for permission to construct telephone lines to connect with a number of towns throughout the county.

DAM, TUNNEL, ETC.—Ogden, Utah.—Bids are asked until Aug. 4 for constructing a rock-filled dam to be 68 ft. high and an outlet tunnel 180 ft. long, for the Davis & Weber Counties Canal Co., as described in our advertising columns. Pres., C. B. Adams; Ch. Engr., W. M. Bostaph; Consult. Engr., Sam'l Forties.

STEAMSHIPS.—Newport News, Va.—Reports state that the Morgan Line Steampship Co., New York, N. Y., has awarded a contract to the Newport News Shipbuilding & Dry Dock Co., at $2,500,000, for the construction of three steamships 400 ft. long, 50 ft. beam and 35 ft. deep, with a capacity of about 5,000 tons each.

CONTRACT PRICES.

MACADAMIZING.—Easton, Pa.—The following bids were received by the county commissioners July 8 for rebuilding the Delaware road to Snyder's Bridge, a distance of about 6½ miles; the roadbed will be 12 ft. wide, and 9 ins. deep for telford, and 6 ins. deep for macadam; total bid, about $20,000; Engr., J. Marshall Young:

*26 and 29 cts. full bid. †This price, 58 cts., covers the furnishing and also the excavation, made by the two bidders. §$75.00 for 1, and $28.00 for 30 manholes. ‡Added to the excavating bid. ‖$4.25 is the price a ft. complete for work in tunnel.

ELECTRIC LIGHTING.—Los Angeles, Cal.—The council received the following bids June 27, 1898, for lighting city with electricity, as described in our issue of June 30: Specifications A—Same system as at present, with 180 new lights, a total of 640 lights; Los Angeles Lighting Co., $6.50 a light; there was no other bid under these specifications. Specifications B—Calling for full 734 lights, removing high poles and substituting for each pole, six arc lights; Los Angeles Lighting Co., $6.70; Edison Electric Co., $6.94. Specifications C—Calling for the construction of a complete pole and wire system, to be owned by the city; San Gabriel Electric Co., $125,930; California Electrical Works, $125,540. Specifications D—For lights alone; California Electrical Co., $7,950 for 500 lights, or $15,000 for 1,000 lights. Specifications E—For furnishing electrical energy for all the lights necessary for lighting the city; San Gabriel Electric Co., $4.25 a light. No bids were received under Specifications F. Specifications G—For power lights and maintenance of a pole and wire system to be owned by the city, 740 lights; the Los Angeles Electric Co., $5.75 a light. The lowest bid of the Los Angeles Lighting Co. is accepted. The city next year will spend for 680 lights, $53,040. This is for all-night, every-night service. This year it spends for 460 lights, midnight, moonlight schedule, $49,680.

MACADAMIZING.—Pekin, Ill.—The following bids were received by the committee of the Citizens Improvement Association for macadamizing a road; the contract being let to the Dunbar Co., Peoria, Ill., for a 14-ft. roadbed, 124 ins. deep, a 12-ton road roller to be used:

	Width of road.	Road roller, tons.	A lin. ft.
Crescent Stone Co., Peoria, Ill	14 ft.	12	$1.04
	14 "	6	.94
	16 "	12	1.10
	16 "	6	1.00
Dunbar & Co., Peoria	14 "	6 to 8	.99
	16 "	6 to 8	1.13
	14 "	..	.94
Campbell & Co., Joliet, Ill	14 "	7½	1.04
	16 "	7½	1.18

BRICK PAVING.—Muscatine, Ia.—We are informed that the following bids were received July 15 for brick paving in districts Nos. 14 and 15; in No. 14 foundation is of old macadam and sand, 6 ins., one course brick; No. 15 foundation, 6 ins. sand, one course brick; J. J. Ryan, Cy. Engr.:

Bids Received at Muscatine, Ia., July 15, 1898, for Brick Paving in Districts Nos. 14 and 15.

Bidder.	District No. 14. Excavation, 7,000 c. yds.	Concrete curb, St., 2,831 lin.ft.	Concrete curb, Alley, 600 lin.ft.	Brick paving 9,400 sq. yds., Buffalo.	Des M'nes.	Total.	District No. 15. Excavation, 4,000 c.yds.	Concrete curb, St., 2,216 lin.ft.	Concrete curb, Alley, 3,000 lin.ft.	Brick paving, 7,075 sq. yds., Buffalo.	Des M'nes.	Total.
E. Baker, Muscatine, Ia.	$0.175	$0.45	$0.39	$0.945	$0.96	$11,616[1]	$0.155	$0.54	$0.39	$0.945	$0.96	$9,663[2]

[1] This total is for Buffalo brick; total for Des Moines, $11,757. [2] This total for Buffalo brick; Des Moines brick, $9,769. [3] Awarded contracts.

ASPHALT PAVING.—Montreal, Que.—Bellhouse, Dillon & Co. have been awarded the contract for asphalt paving in Craig St. at $2.41 a sq. yd.

SUBMERGED WATER PIPE.—Parkersburg, W. Va.—We are informed that the following contract was let July 11, 1898, to Thos. H. Regan & Son, Philadelphia, Pa., for furnishing the material and for constructing a 36-in. submerged pipe, etc., as advertised in Engineering News: Pump Well Section (Section O to near Station 2)—Excavating and timbering tunnel, 7×7 ft. in clear, $8.50 a lin. ft.; cofferdam and excavation at shore, for relaying pipe, $9.50 a lin. ft.; relaying 36-in. pipe in the above section, and back filling, $3.75 a lin. ft.; furnishing and putting in place, new gate or valve (plan submitted), $460. River Section [a] (from near Station 2 to Station 10)—Excavating, furnishing and laying 36-in. pipe in cofferdam, to near Station 7, $11.21 a lin. ft:. dredging out trench and laying pipe from Station 7 to channel, 312 ft., from barges or floats, including flexible joints every four lengths, $10.40 a lin.ft. River Section [b]—Dredging and laying pipe, from barges and floats, from near Station 2 to channel in river, 812 ft., including flexible joints every four lengths, $11.21 a lin. ft.; laying about 700 ft. of 14-in. conduit, from near line of low water to channel (city to furnish pipe), $3.98 a lin. ft.; furnishing and laying 12-in. by-pass, connecting discharging main with 36-in. conduit, $7.45 a lin. ft.; furnishing and putting in place a 12-in. stop valve on by-pass, $37.00; 12-in. "Y" or "T" branch on 36-in. conduit, above the price of straight pipe, $27.60 a lin. ft. The contract was let for the 36-in. conduit on Plan [a] at $12,601. Smaller conduit was not let.

BRICK PAVING.—Swanton, O.—We are informed that the following bids were received July 11, 1898, for brick paving, as advertised in Engineering News; Engrs., Riggs & Sherman, The Nasby, Toledo, O.:

Items.	Thos. McKinney, Toledo, O.	M.F. Bramley Cleveland, O.	Fisher, Kenfer & Bailey, Huntington, Ind.	D. R. McArthur & Co., Kenton, O.	J. C. Carland, Toledo, O.

DREDGING.—Marcus Hook, Del.—Lt.-Col. C. W. Raymond, U. S. Engr., Philadelphia, received the following bids July 5, 1898, for dredging from bulkhead bar and Marcus Hook ice pier, Del., approximate quantity of material to be removed, 1,050,000 cu. yds:

	Cts. a cu. yd.
P. Sanford Ross, Inc., Jersey City, N. J	9⅗
Atlas Dredging Co., Wilmington, Del.	10
American Dredging Co., Philadelphia	7⅔
International Contracting Co., Syracuse, N. Y.	11¾
River & Harbor Improvement Co., Camden, N. J.	6⅞
Baltimore Dredging Co., Baltimore, Md.	10
Morris & Cummings Dredging Co., New York	9
Virginia Dredging Co., Richmond, Va.	8.49
Frank H. Brainard, New York	9½

ASPHALT PAVING.—Philadelphia, Pa.—Aaron Ward is reported to have been awarded the contract for asphalt paving in certain streets, at $1.39 a sq. yd.; total, about $200,000.

CURBING AND GRADING.—Kansas City, Mo.—The following contracts were let July 1, 1898, by the Park Commissioners for curbing and grading at the Paseo: Curbing around the Paseo, 9th to 15th St., Kansas City Sidewalk & Cement Co., 71 cts.; guttering and curbing, $1.05 a ft.; from 15th St. to south end of Paseo, M. Schoonmaker, curbing, 65 cts.; curbing and guttering, $1.05.

PAVING.—Kansas City, Mo.—The following contracts have been let by the public improvements committee for certain paving: Asphalt paving—12th St., Prospect Ave., Forest Ave., Barber Asphalt Paving Co., $2.12 a sq. yd., total, $61,567; Brick Paving—18th St., Fred. Feigel, $1.47¼ a sq. yd., total, $6,779; Roberts St., Walter Hickman, $1.52 a sq. yd.; $2,420; 24th St., Boyd Construction Co., $1.50 a sq. yd., $10,950.

WATER-WORKS.—Cambridge Springs, Pa.—We are informed that the following contract was let July 11, 1898, to Chandley Bros. & Co., Beaver Falls, Pa., for furnishing and constructing works, as advertised in Engineering News; Geo. L. Wade, Cy. Clk.: Furnishing about 456 tons of cast-iron water pipe, $15.30 a ton of 2,000 lbs.; about 20,000 lbs. special castings, 2 cts. a lb.; 37 hydrants, with two 2½-in. hose nozzles and 6-in. bottom connections, $22.50 each; 14 hydrants, with two 2½-in. hose nozzles, and 4-in. bottom connections, $21.00 each; 10 10-in. gate valves, $21,00 each;

3 8-in. gate valves,$15.00 each; 25 6-in. gate valves,$10 each; 16 4-in. gate valves, $6.00 each; 54 valve boxes, for above, $2.25 each; laying 5,904 ft. 10-in. pipe, 20 cts. a lin. ft.; 1,008 ft. 8-in. pipe, 18 cts. a lin. ft.; 11,640 ft. 6-in. pipe, 14 cts. a lin. ft.; 8,208 ft. 4-in. pipe, 12 cts. a lin. ft.; rock excavation in trenches, $2 a cu. yd.; furnishing and setting up two power pumps, $1,800; two gas engines, $1,700; pumping station, as per plans and specifications, $1,305; constructing impounding well, $708; furnishing and erecting steel stand-pipe and foundation, as per specifications, $2,235; connecting tubular wells with impounding well, $215. Total, $20,788. One engine and one pump were eliminated from the contract, also substituting 55-in. pipe for 60-in., made the reduction in total bid on proposal blank; total bid, $18,964.

INDUSTRIAL NOTES.

THE AMERICAN IMPULSE WHEEL CO., 120 Liberty St., New York, has the contract to furnish water wheels for the city lighting station, at Columbus, O.

THE WARREN-SCHARF ASPHALT PAVING CO., New York, is reported to have opened an office at 92 Sparks St., Ottawa, Ont., in charge of Mr. W. G. Mackendrick, Supt.

THE PACIFIC FLUSH TANK CO., Chicago, has removed its Canadian agency from Toronto to Niagara Falls, Ont. Mr. Victor Hill, P. O. Box 245, is the manager of this branch.

THE VIRGINIA BRIDGE & IRON CO., Roanoke, Va., has the contract for an 18-ft. roadway steel highway bridge, consisting of two 140-ft. spans on steel cylinder piers, over the Salunda River, Piedmont, S. C.

THE WELLS LIGHT MFG. CO., 44 and 46 Washington St., New York, reports a large number of shipments of its lights for use at fortifications, for coast defence, etc. The company has also made a large consignment of its lights to Cuba within the past few days.

THE DRESSEL RAILWAY LAMP WORKS, New York, has presented to the engineering laboratory of Purdue University, Lafayette, Ind., a complete outfit of locomotive lamps, consisting of a pair of engine classification lamps, one steam gage lamp and one water gage lamp.

THE BALDWIN LOCOMOTIVE WORKS, Philadelphia, Pa., has received orders for 80 locomotives from the Russian government for the Manchurian Ry. in the nine weeks ending May 31, 1898, and within the previous six months orders were sent to the works for 138 locomotives.

THE BUSHNELL MFG. CO., Easton, Pa., manufacturers of car seats, spiral springs and car berths, is to have its plant sold at receiver's sale, Aug. 17, 1898, as stated in our advertising columns (page xviii.). Mr. Charles Hansel, 43 Cedar St., New York, is the Receiver and Manager.

JOHN F. O'ROURKE, 44 Broadway, New York, engineer and contractor, has received the contract for eight pneumatic caissons for the foundations of the new five-story residence for Mrs. Margaret L. V. Shepard, to be erected at 11 and 13 East 62d St., New York, at a cost of $75,000.

MR. CLARENCE LIVINGSTON BURGER,patent attorney and expert, has associated Mr. Louis B. Adams with him in the practice of patent and trade-mark law, under the firm name of Burger & Adams. The offices of the firm remain in the Postal Telegraph Bldg., 253 Broadway, New York, where Mr. Adams also continues the general practice of law.

THE SHERIDAN IRON CO., Reading, Pa., controlling two of the largest blast furnaces in Pennsylvania, according to report, has been organized, and the following officers elected: Pres., Mr. Thos. Sobarth, London, England.; Secy., Mr. Hugh Lienebeer, London, England; Mr. E. Bird Grubb, Philadelphia.

HUGHES BROS. & BANGS, Syracuse and New York, contractors for river and harbor work, are the owners of seven lighters and three tugs, all new, which the United States government is reported to have given notice that it intends to impress into the service for war purposes, to be used in landing supplies and troops.

THE INTERNATIONAL BRAKE SHOE CO., Chicago, reports that Mr. W. D. Sargent, its President, sailed for Europe last week to make arrangements for the manufacture of the Diamond "S" shoe in several European countries, including Russia. The success of the shoe since its introduction last fall has been little short of phenomenal, and few if any railway devices have been so thoroughly and consistently pushed on all occasions.

THE PITTSBURG BRIDGE CO., Pittsburg, has secured, through Mr. F. C. Black, Spartanburg, S. C., agent for North and South Carolina, the contract for a 105-ft. steel highway bridge over South Tiger River, near Duncans, S. C.

THE WROUGHT IRON BRIDGE CO., Canton, O., through its agents, Wynkoop & Braly, 1 and 3 Union Square, New York, has received the following contracts. New steel bridge at Whippany, near Morristown, N. J.; steel work for the new building of the New York Sugar Refinery Co., Brooklyn, N. Y., and seven steel bridges from the board of chosen freeholders, Flemington, N. J.

THE W. S. DICKEY CLAY MFG. CO., Kansas City, Mo., opened its new works for the manufacture of sewer and culvert pipe, etc., at Deepwater, Mo., June 27, replacing the plant destroyed by fire last August. The company's property at Deepwater consists of 320 acres of fine clay and coal lands, on which are located two plants, one devoted to the manufacture of sewer pipe and the other to that of building brick, unglazed tile, vitrified and fire brick. The new buildings are of brick, of the company's manufacture, and consist of a main building, 82 × 322 ft., four stories in height; an annex 97 ft. square of the same height, and a power building, 60 × 80 ft., with an iron truss roof, containing three 300-HP. Babcock & Wilcox boilers. The machinery is driven by a Hamilton-Corliss engine, and the plant is lighted by a Fort Wayne Electric Corporation dynamo, operated by a McAlfree high-speed engine. The building also contains two Worthington steam pumps taking water from an artificial lake, 30 ft. deep and several acres in extent, which gives a natural pressure for fire protection.

THE WALKER CO., Cleveland, O., has a contract from the Union Carbide Co., Chicago, consisting of twenty 500-HP. single phase, alternating current dynamos, to deliver a current of 2,500 amperes at 200 volts, and five 100-HP. direct current dynamos, as exciters, besides a complete switchboard for all of the dynamos. The plant will be installed at the falls at Sault Ste. Marie, Mich., where calcium carbide will be produced on the largest scale ever attempted. The Union Carbide Co. has acquired the rights of manufacture for the United States, it is stated, and will make the above its main works. They are being built to accommodate 40 dynamos and an equal number of electric furnaces, in which the lime and carbon are fused into calcium carbide.——On account of the rush of work and the consequent need of additional space, the company has found it necessary to add to the large machine shops at its Cleveland works. The machine shops alone consist of three bays each 400 ft. long and the addition will consist of a fourth bay. Work is being rapidly pushed and the new bay will be shortly completed and ready to receive the large machine tools that are to be placed there.

THE PELTON WATER WHEEL CO., San Francisco, Cal., reports a satisfactory business for the first half of this year. Stations for electric power transmission continue to be an important feature of the business of the company, and among its more recent contracts are the following: A 1,200-HP. plant to operate the Odawara Electric Ry., Japan; the wheel to run under 400 ft. head; 650 HP. to operate a cotton factory in Japan; 500 HP. for the Blue Lakes (Cal.) electric power plant; 300 HP. for the Auburn, Cal., station of the Central California Power Co.; 1,800 HP. for the Tuolumne (Cal.) Electric Power Co.; 750 HP. for the Griffith mine, Tuolumne, Cal.; 250 HP. for the Ventura (Cal.) Electric Light & Power Co.; 1,200 HP. for a British Columbia railway company; 250 HP. for the Salt Lake & Ogden Ry.; 300 HP. for the Farfan Electric Power Co., Peru; seven wheels for the California Powder Works, Santa Cruz, Cal.; four wheels to run air compressor plants in Alaska; nine wheels for various mining companies in Alaska and British Columbia; three wheels for Central America; seven wheels for various mining purposes in Mexico, and 13 wheels for similar purposes in Utah, Montana and Idaho.

THE WESTINGHOUSE ELECTRIC & MFG. CO., Pittsburg, has just sold to the Manufacturers' Building Co.,Providence, R. I., a 250-K-W. 500-volt Westinghouse engine-type dynamo, running at 100 revolutions a minute, to be driven by an Armington & Sims Corliss engine, which will supply power for the operation of motors in the various manufacturing departments of the Manufacturers' building, said to be one of the largest and best equipped power buildings in the United States. The engineering features are under the direction of Lewis & Claflin,consulting engineers. The building has accommodations for upwards of 60 manufacturing concerns, being particularly equipped with conveniences for the production of jewelry, specialties, etc.——The company has installed a large amount of apparatus for the production of refined copper by electrolytic processes, one of the principal installations being at the refinery of the Anaconda Copper Co., Anaconda, Mont., where 10 dynamo of 270 to 300 K-W. capacity have been installed. Another large installation is that of the Boston & Montana Consolidated Copper & Silver Mining Co., Great Falls, Mont., where two 810-K-W. Westinghouse engine-type dynamos are in service.——The Raritan Copper Works, Perth Amboy, N. J., is about to erect a large copper refinery, and has contracted with the Westinghouse company for three 600-K-W. 150-volt engine-type dynamos, making 150 revolutions a minute, with a nine-section switchboard for electrolytic service, and the operation of two 75-K-W. 220-volt engine-type dynamos, which will be used for lighting and power service. This installation, it is stated, will be the most complete of its kind in the world.

NEW COMPANIES.—Long Island Sand Co., 76 Montgomery St., Jersey City, N. J.; $5,000, commencing with $1,080; to deal in all kinds of sand, stone, lime, etc.; Chas. P. Smith, Jersey City; W. J. Timberman, Maywood, N. J.; Lindley M. Franklin, Flushing (L. I.), N. Y.; Wm. E. R. Smith, East Orange, N. J.; E. B. Archer, Hackensack, N. J.

Daylight Glass Co., New York; $505,000, commencing with $600; to manufacture and deal in prismatic glass, etc.; G. K. Cummings, Fort Wadsworth, N. Y. H.; Richard Wagner, William Weterer, J. H. Steinhart and F. A. Ballard, all of New York.

Edgerton Press & Mfg. Co., Jersey City, N. J.; $100,000, commencing with $1,000; to manufacture presses for the treatment of tankage, etc.; Charles Edgerton, E. G. Maturin, Wm. W. Gooch, Horace J. Ettridge and Geo. C. Du Bois, all of 60 Grand St., Jersey City.

Pianophone Co., New York; $300,000, commencing with $50; to manufacture and deal in mechanical specialties; C. W. Youngman, J. R. Lowther, J. L. Schrader, E. G. Boltz and M. A. Jones, of New York.

Philadelphia Utilization Co., Philadelphia, Pa.; $100,000, commencing with $2,500; to manufacture fertilizers, lubricating greases, etc.; William Layer, Wm. H. Wade, Benjamin F. Howland and C. B. Livezey, all of Philadelphia; S. B. Schenck, Newark, N. J.

International Improved Combustion Co., Middlebury, Vt.; $3,000,000, commencing with $100; to manufacture and sell stoves, furnaces, etc.; Robert Cartmell, Allan Calhoun and Oliver Severance, all of Middlebury; C. R. Witherall, Cornwall, Vt.; Dr. J. S. Dodge, Lincoln, Vt.

West Virginia Grubber & Tool Co., Charleston, W. Va.; $100,000, commencing with $50; to manufacture and sell improved farming implements; G. W. Atkinson, U. S. Laidley, H. C. McWhorter, J. A. de Gruyter and Fred Gardner, all of Charleston.

Frank M. Pierce Engineering Co., New York; $10,000; Frank M. Pierce and Philo B. Tingley, New York; George F. Tremain, Hoboken, N. J.

National Boiler Works Co., Syracuse, N. Y.; $40,000; William M. Wood, Media, Pa.; Howard N. Babcock, Syracuse; H. T. Webb. Skaneateles; Robert Joy, Oswego.

Titian Steel Co., Chicago, Ill.; $500,000; Eugene E. Prussing, Frank H. McCulloch, Edward Bernman.

Chicago Portland Cement Co., Chicago, Ill.; $250,000; David R. Fraser, Norman Fraser, Ralph Bates.

Wheeler Compensating Motor Co., Louisville, Ky.; $25,000; to manufacture and sell engines, locomotives, etc., and a rotary compensating motor, patented by Mr. Wheeler; Robert Hewitt Wheeler, S. L. Mason, J. W. Seaton.

Austin Portland Cement Mfg. Co., Austin, Tex.; $50,000; to manufacture cement; E. G. Stolley, A. T. Rose, S. Silverman.

Litchfield Machine Co., Litchfield, Ill.; $50,000; to erect a plant for the manufacture of machinery; S. M. Grubbs, George W. Amsden, E. A. Amsden.

Joseph J. Gleason Co., New York, N. Y.; $10.000; to construct buildings upon property under the leases made by the Manhattan Ry. Co.; Joseph J. Gleason, Michael J. Drummond, William H. Huxley, Frederick D. Mason, New York

Seamless Metal Ware Co., New York, N. Y.; $150,000; to manufacture metal ware; E. G. Fabbri and Allessandro Fabbri, Scarborough, N. Y.; Adolphe E. Borie, Benoni Lockwood, Jr., and Edmund L. Zalinski, New York.

A. L. Sweet Iron Works, Medina, N. Y.; $200,000; Albert L. Sweet, L. M. Sweet, Arthur J. Howard, F. Marion Poler, Albert S. Braughton, Medina.

Stanton Mfg. Co., Portland, Me.; $1,000,000, commencing with $70; to manufacture and deal in machinery; Louis C. Stanton, Pres., Newton, Mass.; G. F. Cunningham, Treas., Boston, Mass.

Phoenix Foundry Co., Pittsburg, Pa.; $12,000; John Jackson, Allegheny; Peter Newlands, Harry Newlands, John P. Provost, Daniel Bingham, Pittsburg.

Southern Illinois Construction Co., East St. Louis, Ill.; Charles L. Gray, Frank L. Thrasher, William J. Eddinger.

Star Mfg., Chemical & Commercial Co., Syracuse, N. Y.; $100,000, commencing with $50; G. O. Chilton, Charles W. Smith, D. M. Black, E. H. Carwithen and H. H. White, Charleston, W. Va.

Bushnell Telephone Co., Chicago, Ill.; $5,000; Joel Lightner, E. E. Johnson, H. A. Cleveland.

International Construction & Improvement Co., Fort Smith, Ark.; $1,000,000; to construct railways, bridges, etc.; Jesse French, John L. French, John Dooley, St. Louis; H. D. Mackay, Ponoma, Mo.; J. S. Drake, Fort Smith.

Buffalo Telephone Co., Buffalo, Wyo.; $5,000; to construct and operate a telephone and telegraph line between Buffalo and Sheridan and other points; C. H. Parmelee, Robert Fotec, W. J. Thom and others.

Reserve Construction Co., Cleveland, O.; $10,000; to construct telephone, telegraph and railway lines and electric plants; S. Prentiss Baldwin, B. Mahler, James B. Hogg, Fred S. Barton and Charles W. Mason.

Oklahoma Telephone Co., Oklahoma City, Okla.; $100,000; to build, sell and operate telephones throughout Oklahoma territory; Harry C. Barter and George R. Gorden, Browningtou, Mo.; Wm. E. Moore and McGregor Douglass, Oklahoma City.

Illinois Telephone & Telegraph Co., Chicago, Ill.; $250,000; Ralph N. Bowman, Samuel N. McLaughlin and Thomas J. Holmes.

Mountain Home & West Plains Telephone Co., Mountain Home, Ark.; $5,000; C. W. Brown, Pres.; M. N. Dyer, B. E. Massey, R. C. Paul, W. F. Eatman and R. C. Love.

Monmouth Telephone Co., Monmouth, Me.; $10,000, with $250 paid in; to operate lines in Monmouth, Wayne and Litchfield; Pres., J. H. Gilman; Treas., H. M. Blake, Monmouth.

Atchison Telephone Co., Topeka. Kan.; $20,000; Ed H. Berry, C. D. Walker, George Storch, J. T. Hersey and S. A. Frazier.

Beverly & Marlinton Telephone Co., Huttonsville, W. Va.; $5,000; Perry Bosworth, J. L. Bosworth, of Huttonsville; A. S. Bosworth, of Beverly; T. C. Russell and C. A. Barlow, of Cricord.

Franklin Telephone & Telegraph Co., Philadelphia, Pa.; $40.000; Pres., D. K. Appenzellar; Secy., H. B. McNulty; Treas., Dr. David Maclay; T. M. Mahon, D. L. Grove, Isaac Lesher, W. I. Minick, John C. Gerbig, Dr. J. O. Skinner, Dr. R. W. Ramsey, A. N. Pomeroy, Alexander Stewart, H. E. Holtsizer, T. J. Kennedy, R. S. Smiley, A. S. Stover. W. C. Hull, John Zullinger, C. C. Gelwicks, Christian Brechbill.

Eastern Solar Gas Machine Co., New York; $100,000; to manufacture machinery for the use of acetylene gas; Walter C. Butler, Orange, N. J.; John U. May and Arthur J. Stewart, Cleveland, O.; J. Severin Charlesson, Calvin Tompkins, John De Witt Warner and Charles A. Wimpfheimer, New York.

Chase Carbide & Gas Generator Co., Portland, Me.; $300,000, commencing with $50; to generate and deal in acetylene gas; Pres., Louis C. Stanwood, Newton; Treas., Edward B. Hitchcock, Newton.

New York Kerosene Oil Engine Co., New York; $50,000; to manufacture kerosene oil, gas. steam and electrical engines and motors for marine and industrial uses; Feodor C. Hirsch, 606 East 134th St., and George R. Moran, New York; James W. Eaton, West Islip, (L. I.), N. Y.

Union Bridge Co., Trenton, N. J.; $1,800,000; to construct public works; Joseph Mayer, E. Ludlow Gould, Nathaniel Haven. Charles S. Smith, New York, and George A. Miller, Montclair.

California Dredging Co., San Francisco, Cal.; $25,000, commencing with $18,088; Wm. E. Palmer, Fred S. Mayhew, Fruitvale, Cal.; William M. Klink, Luther J. Holton, Frank B. Peterson and S. W. Cheyney, San Francisco; J. M. Goodman, Alameda, Cal.

Home Telephone Co., Marion, Ia.; $5,000; J. S. Alexander, Pres.; Geo. M. White, Vice-Pres.; F. C. Schminke, Secy.; T. J. Davis, J. S. Ovington, William M. Downie and C. L. Nye.

Eureka & Mound City Telephone Co., Eureka, Minn.; $2,000; F. W. Boettcher, Walter C. Poehler, Eureka; Louis H. Clyborne, Chauncey E. Eckhart, Mound City; Alvin H. Poehler, Minneapolis.

Montour & Columbia Telephone Co., Vanville, Pa.; $25,000; to run lines in Columbia and Montour counties; James H. McDevitt, C. M. Clement, Sunbury; R. K. Polk, F. C. Angle, E. Carman, C. P. Hancock, Danville; H. E. Murty and J. P. Helfenstein, Shamokin.

Missouri & Iowa Telephone Co., Princeton, Mo.; $25,000; J. S. Rogers, H. G. Orton, E. M. Hyde and others.

Winston Telephone Co., Princeton, Mo.; $1,000; G. Orton, J. B. Hyde, C. P. Rogers and others.

Wilson Mfg. Co., New York; $600; E. K. Baber, Keeseville, N. Y.; R. F. Wilson, East Orange, N. J.; R. E. Oatman, John Leighton and W. W. Tucker, of New York.

Huntington Mining Co., New York; $1,000; C. W. Bradley, G. H. Huntington and D. F. Lloyd, of New York; William Berden, Paterson, N. J.; and James H. Brown, Rutherford, N. J.

Hooker Steam Pump Co., St. Louis, Mo.; $30,000; J. E. Gorman, W. D. Hooker, W. C. Farrar and R. L. McLaren.

Overland Dry Concentrating Co., Lincoln, Neb.; $550,000; Ed. Bignell and Jesse S. Waugh, all of Lincoln; Eugene Waugh, Denver, Colo.

National Arc Lamp Co., Berwick, Me.; $10,000, commencing with $300; to manufacture and deal in electrical and other mechanical devices; Pres., C. C. Barton, Framingham, Mass.; Treas., John R. Hosmer, Boston, Mass.

Standard Quarrying & Construction Co., New York; $1,000,000; Walter J. Roberts, Henry E. Parsons and John F. Clark, New York; offices at Phœnix, Ariz., and New York.

Oklahoma Telephone Co., Oklahoma City, Okla.; $100,000; to build, own, buy, sell and operate telephone lines throughout Oklahoma territory; Harry C. Barter and Geo. R. Gorden, Brownington, Mo., Wm. E. Moore and McGregor Douglass, Oklahoma City.

M. S. Friede Co., New York; $20,000; to supply railway equipments; M. Sergery Friede, 18 East 106th St.; Jos. S. Friede and Harry Harris, all of New York.

Manning Signal Light Co., Des Moines, Ia.; $100,000; to manufacture and dispose of the Manning signal light, which Mr. Manning has invented and has patented with special adaptations to railway work; Edward S. Manning, H. J. Mills, Samuel Compton, C. A. Bishop, W. D. Sheehan.

Cuban Development Co., Jersey City, N. J., incorporated in West Virginia; $5,000,000, commencing with $2,500; to cultivate land in Cuba, and to construct railways, electric light plants, water-works, etc.; Carroll Burman, Washington, D. C.; Julian Cendoya, Bethlehem, Pa.; S. J. Dickerson, G. A. Denham and Raymond Moore, of New York.

Ashburnham Mfg. Co., Boston, Mass.; $1,000,000, commencing with $500; to manufacture railway cars and appliances, etc.; H. W. Bates, John D. Huhn and R. L. Stedman, of Boston; E. A. Petit and E. D. Luxton, of New York.

Feliz Sugar Co., New York; $500,000, commencing with $200; to manufacture and deal in sugar; Michael Dillon, Frederick Blasenbrey, Robert Wheelan, Morris Cooper and S. I. Kelton, all of New York.

Avor Brick Co., 76 Montgomery St., Jersey City, N. J.; $100,000, commencing with $2,000; to manufacture and work clay, metals, etc.; David P. Van Deventer, Jr., Alfred C. P. Quimby and Edward A. O'Collaghan, of 76 Montgomery St., Jersey City; August C. Rader, Montclair, N. J.

Hadaway Electric Heating & Engineering Co., New York; $50,000; Harold S. Mackaye, 225 West 106th St.; Harcourt Brigham and Nelson Hiss, all of New York.

PERSONAL.

Mr. J. Foucart has been appointed City Engineer of Guthrie, Okla.

Prof. E. E. Lawson has opened an office in Dayton, Pa., as a civil engineer and surveyor.

Messrs. Benj. G. Ingalls, Chas. S. Haskell and M. V. B. Jones have been appointed Water Commissioners of Swampscott, Mass.

Mr. Albert E. Loomis has been appointed a member of the Board of Sewer Comissioners, of Oneida, N. Y., to succeed Mr. John V. Richardson, resigned.

Mr. Clifford Lewis, Jr., City Surveyor of Utica, N. Y., has resigned to accept the position of Inspector of Bridges on the Middle Division of the New York Central & Hudson River R. R.

Mr. Peter J. Nichols, General Superintendent of the Union Pacific R. R., with headquarters at Omaha, Neb., has been appointed General Superintendent of the Omaha Bridge & Terminal Ry., a newly created position.

Mr. Ernest W. Bowditch, Jun. Am. Soc. C. E., of 60 Devonshire St., Boston, Mass., has resigned his position as Consulting Engineer and Landscape Gardener of the Park Board of Cleveland, O., which he has held for the past five years.

Col. Charles S. Riche, of the First U. S. Volunteer Infantry, until recently First Lieutenant in the Corps of Engineers, U. S. A., stationed at Galveston, Tex., was married July 16 in that city to Miss Susan Horton Gadberry, of Denison, Tex.

Mr. Fingal C. Black, formerly County Engineer of Spartanburg county, South Carolina, has been commissioned a First Lieutenant in the Third Regiment of United States Volunteer Engineers and has been appointed enrolling officer, with headquarters at Spartanburg.

Col. George E. Waring, Jr., M. Inst. C. E., of New York city, has declined the position which it was stated in this column last week had been offered him, of Consulting Engineer and New York representative of the Dunning Engineering & Construction Co., of Scranton, Pa.

Messrs. Charles A. Schieren, Andrew H. Green, Hugh Kelly, Christopher C. Shayne and Alexander R. Smith, all of New York city, have been appointed by Governor Black as a commission to inquire into the decline of the commerce of that city and suggest legislation to foster its increase.

Mr. Walter C. Allen, Superintendent of Lamps, of Washington, D. C., has been appointed by the District Commissioners Chief Electrical Engineer of the District of Columbia, in charge of the fire alarm, telephone and telegraph systems, electrical conduits, electric railways, etc.

Mr. William L. Darling, M. Am. Soc. C. E., Division Engineer of the Northern Pacific Ry., with headquarters at St. Paul, Minn., has been appointed Assistant Chief Engineer of that railway, a new position. He will have jurisdiction over all lines east of Billings, Mont., with headquarters as heretofore.

Mr. Ferdinand W. Peck, of Chicago, Ill., has been appointed Commissioner-General to the Paris Exposition by President McKinley. He is a graduate of the University of Chicago, of which he is a Trustee, and was Chairman of the Finance Committee of the World's Columbian Exposition of 1898. He will establish his offices at once in the Auditorium Bldg., Chicago.

Mr. Harry C. Southworth, civil engineer, of Stoughton, Mass., was married July 11 to Miss Elizabeth Josephine Hill, of Dedham Centre, Mass. Mr. Southworth was a member of the railway commission on the abolition of the grade crossings on the New York, New Haven & Hartford R. R. Miss Hill has been for some time Supervisor of Drawing in the public schools of Lexington and Braintree.

Mr. Gaylord Thompson, M. Am. Soc. C. E., has been appointed by the common council of Rochester, N. Y., as expert engineer to assist the city assessors in the preparation of the assessment for the East Side trunk sewer, which was designed by Mr. Emil Kuichling, M. Am. Soc. C. E., about ten years ago, and was built by a special commission created for that purpose. It cost nearly $1,000,000, which amount, together with accumulated interest, has now to be assessed upon the territory benefited. Mr. Thompson recently completed the construction of the West Side trunk sewer, also built by a special commission, and which cost about $600,000. The first assessment for the latter sewer, made in 1893, was the subject of such bitter controversy that it was set aside by the legislature in 1895; the commission was reorganized, with Mr. Thompson as engineer, and a new assessment was made which has since met with general approval.

Mr. U. S. G. White, Civil Engineer, United States Navy, who has been recently tried by court-martial on the charge of culpable negligence in connection with the failure of the new Dry Dock No. 3 at the New York Navy Yard, Brooklyn, as stated in our issue of June 23, has been sentenced to be placed on furlough pay for three years and to retain his present position on the list of officers of the same rank, until he shall have lost two numbers. Mr. White was in temporary charge of the work during the absence of Mr. A. G. Menocal, M. Am. Soc. C. E., whose trial was referred to in our issue of June 9.

OBITUARY.

Mr. Richard J. Kessler, contractor, of Reading, Pa., died July 16, aged 43.

Mr. Jesse Hubbard, contractor, of Milwaukee, Wis., died July 22, aged 86.

Mr. F. H. Holly, Superintendent of Water-Works, of Paducah, Ky., died July 23.

Mr. Shepard Allen, railway contractor, of Birmingham, Ala., died July 21, aged 47.

Maj. Wilbur D. Fiske, of the Knowles Steam Pump Co. and the George F. Blake Mfg. Co., died at Melrose, Mass., July 20. He was a veteran of the Civil War, and for many years was a member of the Melrose Water Board, most of the time as its Chairman.

Mr. Ezekiel W. Woodward, civil engineer, died at his home in Tatham, Mass., July 19. He was born in Westmoreland, N. H., Dec. 4, 1828, and at the age of 17 began his career on the preliminary survey of the Cheshire R. R. in that state. He was employed as a rodman and assistant engineer until the early 50's, when he went to Cincinnati, O., and assisted in laying the first T-rail on the Little Miami Ry. He next served as Assistant Engineer of the location and construction of the Cincinnati, Hamilton & Dayton Ry. and on the surveys for the Dayton & Michigan R. R. In 1851 he became the Chief Engineer of the Cincinnati, Wilmington & Zanesville Ry., and in 1855, Superintendent of the Steubenvile & Indiana R. R. He made the surveys for the La Crosse & Milwaukee R. R., and on its completion entered the service of the Ohio & Mississippi R. R., later being advanced to the Superintendency of the Eastern Division. In 1860 he was appointed Superintendent of the Little Miami Ry., and in 1867 was elected President of the company. He held this office for a year, and then resigned to take part in the organization of the Cincinnati & Newport Bridge Co., and was Consulting Engineer for the bridge built by that corporation across the Ohio River at Cincinnati. He was elected President of the Indianapolis & St. Louis R. R. in 1871, and held the office until July, 1875. On Dec. 20, 1878, he was appointed Commissioner to sell the St. Louis Bridge & Tunnel Company's property, after which he was elected Vice-President of the reorganized company, and held the office until Oct. 8, 1881, when he retired from active business.

ENGINEERING SOCIETIES.

COMING TECHNICAL MEETINGS.

WESTERN SOCIETY OF ENGINEERS.
Aug. 3. "Establishment of Street Grades," Chas. P. Chase. Secy., N. L. Litten, Monadnock Block, Chicago, Ill.

OHIO INSTITUTE OF MINING ENGINEERS.
Aug. 4. Summer meeting, Toledo, Ohio. Secy., Robert M. Hazeltine, Columbus, O.

TECHNICAL SOCIETY OF THE PACIFIC COAST.
Aug. 5. Secy., O. Von Geldern, 819 Market St., San Francisco, Cal.

CIVIL ENGINEERS' CLUB OF CLEVELAND.
Aug. 9. Secy., Wm. H. Searles, Case Library Bldg., Cleveland, O.

MONTANA SOCIETY OF ENGINEERS.
Aug. 13. Secy., A. S. Hovey, National Bank Bldg., Helena, Mont.

ENGINEERS' CLUB OF MINNEAPOLIS.
Aug. 15. Secy., H. E. Smith, 1620 S. E. 4th St., Minneapolis, Minn.

ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.
Aug. 16. Secy., R. A. Fessenden, 410 Penn Ave., Pittsburg, Pa.

WESTERN FOUNDRYMEN'S ASSOCIATION.
Aug. 17. Secy., B. M. Gardner, 1522 Monadnock Block, Chicago, Ill.

NEW ENGLAND ROAD MASTERS' ASSOCIATION.
Aug. 17. Annual meeting, Boston, Mass. F. C. Stowell, B. & M. R. R., Ware, Mass.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.
Aug. 18 to 20. Annual meeting at Massachusetts Institute of Technology, Boston, Mass. Secy., Albert Kingsbury, Durham, N. H.

AMERICAN MATHEMATICAL SOCIETY.
Aug. 19-20. Annual meeting, Boston, Mass. Secy., F. N. Cole, Columbus University, New York city.

AMERICAN CHEMICAL SOCIETY.
Aug. 22-23. Annual meeting, Boston, Mass. Secy., Albert C. Hale, 551 Putnam Ave., Brooklyn, N. Y.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.
Aug. 22-27. Annual meeting, Boston, Mass. Secy., F. W. Putnam, Salem, Mass.

GEOLOGICAL SOCIETY OF AMERICA.
Aug. 23. Annual meeting Boston, Mass. Secy., H. L. Fairchilds, Rochester, N. Y.

AMERICAN INSTITUTE OF MINING ENGINEERS.
Oct. 18. Annual meeting Buffalo, N. Y. Secy., R. W. Raymond, P. O. Box 223, New York city.

ENGINEERS' CLUB OF MINNEAPOLIS.—A regular meeting of this club was held July 18, at which the report of the committee of the American Society of Civil Engineers on "Standard Specifications for Cement Testing" was considered.

ST. LOUIS RAILWAY CLUB.—The last meeting of this club was held June 25 on board the steam ferryboat "Andrew Christy." Mr. William H. Bryan read a paper entitled "Recent Improvement in St. Louis Ferries." The various improvements were inspected, the "Christy" carrying the party to and from the railway terminals.

THE AMERICAN INSTITUTE OF MINING ENGINEERS will hold its annual meeting at Buffalo, N. Y., commencing Oct. 18, 1898. The local committee of arrangements has been appointed from the Engineers' Society of Western New York, and communications may be addressed to the President of the Society and Chairman of the committee, Mr. W. C. Johnson, Niagara Falls, N. Y. Further particulars will be given in a later circular. An excursion, at reduced rates, to the Omaha Trans-Mississippi and International Exhibition will be organized at the close of the Buffalo meeting, provided that a sufficient number of members notify Secretary R. W. Raymond of their intention to join such an excursion.

AMERICAN STREET RAILWAY ASSOCIATION.—The following preliminary list of papers is announced by Secretary T. C. Pennington for the annual meeting scheduled for Boston, Sept. 6-9:

"Maintenance and Equipment of Electric Cars for Railways," M. S. Hotchkiss; "To What Extent Should Railway Companies Engage in the Amusement Business," W. H. Holmes; "The Carrying of United States Mail Matter on Street Railways," W. S. Dimmock; "The Comparative Earnings and Economy of Operation Between Single and Double Truck Cars for City Use," Richard McCulloch; "Inspection and Testing of Motors and Car Equipment by Street Railway Companies," Frederick B. Perkins; "Cost of Electric Power for Street Railways at Switchboard; Both Steam and Water," R. W. Conant.

NEW ENGLAND ROADMASTERS' ASSOCIATION.—The 16th annual convention of this association will be held at Boston, Mass., Aug. 17-18, with headquarters at the Revere House. It is desired that those wishing to exhibit models or samples of railway apparatus notify the secretary, Mr. F. C. Stowell, on or before Aug. 14.

The following topics will be discussed and later reported upon by committees:

Minimum and maximum opening at ends of rails in their renewal: length of rails: diameter of bolts and holes in rails and joint bars; number and position of bolts and slots used.

Switch targets: Shall they be double or single, i. e.: Shall they show or not show a target for main line? Should not switch targets for main line switches be differently colored than targets for sidetrack switches?

What is the best wood for railroad ties: at what season of the year should it be cut for the best preservation of the timber? What advantages, if any, have metal ties over wood?

Should gage of tracks be widened on curves? If so, what should be rate of increase per degree of curvature and what the maximum limit of increase? What is the best method of preventing rails from creeping?

The use of cast or wrought-iron pipe for replacing box culverts. How large pipe can be used with safety: the greatest as well as the least amount of material advisable top of pipe. Cost compared with first and second-class masonry.

Mr. F. C. Coates, N. Y., N. H. & H. R. R. will read a paper on "Recent Experiments in Tamping Ties by Compressed Air."

F. C. Stowell, Secy.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE: Mechanical Science and Engineering Section.—The following is the preliminary programme of this section as given out by Prof. John J. Flather, Lafayette, Ind., who is acting secretary. The regular secretary, Prof. W. S. Aldrich, is at present on the U. S. repair ship "Vulcan:" "High-speed Influence Machines," Chas. W. Warner, Cambridge, Mass.; "The Development of the Topographic Work of the United States Geological Survey and its Application to the Solution of Economic and Engineering Problems," Charles D. Walcott, Washington, D. C.; "Instruments and Methods of Hydrographic Measurements used by the United States Geological Survey," F. H. Newell, Washington, D. C.; "Proposed Methods of Determining the Frequency of Alternating Currents," Carl Kinsley, Falls Church, Va.; "On the Efficiency of Refrigerating Plants," Prof. Storm Bull, Madison, Wis.; "Some Experiments on a New Form of Impact Testing Machine," Prof. W. K. Hatt, Lafayette, Ind.; "On a Dynamometer Car and Its Equipment," Prof. L. P. Breckenridge, Champaign, Ill.; "An Integrating Dynamometer for Measuring the Work Done in Drawing a Train," Prof. Thomas Gray, Terre Haute, Ind.; "A Combined Absorption and Transmission Dynamometer for Laboratory Purposes," Prof. J. J. Flather, Lafayette, Ind.; "On the Measurement of Train Resistance by Dynamometer," Prof. F. C. Wagner, Terre Haute, Ind.; "On the Use of Platinum Resistance as a Pyrometer in Boiler Tests," Prof. F. C. Wagner, Terre Haute, Ind.; "A Comparison of the Efficiency of the Rheostat and the Series-Parallel Controller for Electric Cars," Prof. Thomas Gray, Terre Haute, Ind.; "Note on a Curious Example of Elastic Eolotropy in Steel," Prof. Thomas Gray, Terre Haute, Ind. Other papers will be presented, the subject of which will be announced later.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.—The program for the 6th annual meeting of this society to be held Aug. 18-20 in Boston, Mass., has just been announced. The meetings will be held at the

Massachusetts Institute of Technology, Room 22 Walker Bldg. During the three days the following papers will be presented:

Aug. 18: Address, President John B. Johnson; "The Mutual Adjustment of Class-room and Laboratory Instruction, Gaetano Lanza; "The Mounting of a Spherical Blackboard," A. E. Haynes; "Notes on the Organization of an Engineering Laboratory," H. B. Smith; "The Correct Theory and Method of Organization and Conduct of Professional Schools," R. H. Thurston; Report of the Committee on Entrance Requirements, H. W. Tyler, Chairman.

Aug. 19: "Some Phases of Engineering Education in the South," J. J. Wilmore; Report of the Committee on Uniformity of Symbols, T. C. Mendenhall (Chn.); "The Study of Electricity in Courses Other than Electrical," J. P. Jackson; "A Course in Industrial Chemistry for Technical Schools," F. L. Dunlap; "A New Laboratory Apparatus for Illustrating Longitudinal Impact," W. K. Hatt; "The Direct Study of Thermodynamics," S. A. Reeve; "Laboratory Instruction in Electrical Engineering," R. B. Owens; "A Course in Highway Engineering for Civil Engineers," W. R. Hoag; 'Notes on Some Methods in Use in an Engineering Laboratory," F. C. Caldwell.

Aug. 20: "Sanitary Science as a Part of Every Science Course," W. T. Sedgwick; "The Conduct of Thesis Work," Edgar Marburg; "The Construction of Models by Students as an Aid in Teaching Descriptive Geometry," H. S. Jacoby; "The Training of Engineers for the Maintenance of Way Department on Railroads," J. C. Nagle.

The sessions will be held mornings and evenings, leaving the afternoons free for excursions or trips of inspection. Election of officers, appointment of committees and other general business will take place at the close of the last session.

PACIFIC COAST ELECTRIC TRANSMISSION ASSOCIATION.—The second annual convention of this association was held June 21 at the Cliff House, San Francisco, Cal. The first session, beginning 2.30 p. m., was executive, during which the various reports were read and acted upon, new members were elected, and the following officers were selected for the ensuing year:

President, W. Frank Pierce, Pres. of the Blue Lakes Water Co.; Vice-President, Carroll N. Beal, Secy. and Treas. of the Power Development Co.; Secretary, Geo. P. Low, editor and proprietor of "The Journal of Electricity;" Treasurer, William Angus, Secy. of the Standard Electric Co., of California; Executive Committee, the officers named, and Dr. C. Van Nordon, Pres. Central California Electric Co.

In opening the convention proper the president briefly stated the objects of the society which bore the same relation to the Pacific Coast electrical interests that the National Electric Association does towards Eastern electric companies.

The first paper, "Random Notes on Extremely High Potentials," by Leon W. Bly, was read by the secretary in the absence of the author. This was a brief review of some of the experiments with practical high tension transmission during the last two years and a statement of the conclusions to be drawn. These dealt mainly with the construction and insulation of the transformers and in a few words are: that manufacturers will guarantee transformers for services up to 60,000 volts, but 35,000 may be selected as a present safe limit. In very high tension work high efficiency is obtained by a sacrifice of insulation or regulation qualities; oil is an indispensable medium for insulation; a very high safety factor must be used in designing; in bringing out terminals the greatest care must be observed, and high tension coils should be subdivided and properly spaced.

In all apparatus, such as switches, instruments, etc., a liberal space allowance must be made to prevent arcing.

In transmission circuits the pin and insulator should be considered an integral part, and while iron pins add strength they are a constant invitation to puncture. Capacity on high potential lines is receiving more attention, and while this could be balanced by reactance such a remedy affected the regulation of the line. The discussion which followed was practically all opposed to the author's recommendation of the use of oil, it being stated that air blast types of transformers were the most satisfactory and easiest repaired.

The fact, not heretofore properly considered, that the insulation materials used in transformer construction are subject to a somewhat rapid deterioration under the continuous strain of actual work was pointed out.

At the evening session a paper "On the Electrical Operation of Centrifugal Pumps," prepared by Mr. John Richards, was read by Mr. Robert McF. Doble. This was a description of a plan submitted to the Drainage Commission of New Orleans, La. In a letter contributed by the author and read in connection with the paper, was given the following table, which he employs in designing centrifugal pumps. This table shows that the common opinion that these pumps can only be designed for a constant head is a mistake. From the table it will be seen that a pump running at a constant speed may operate at any head over a considerable range:

Head to produce the flow, ft.	Flow in ft. per minute.	Discharge, galls. per in. of area.
0.5	240	12
0.6	300	15
0.75	360	20
1.0	480	25
2.0	600	31
2.5	720	37
4.0	900	46
7.0	1,200	62

NEW PUBLICATIONS.

THE RELATION OF WATER TO TYPHOID FEVER.—A Lecture Delivered Before the Faculty and Students of the Ohio State University, Columbus, O., Feb. 7, 1898, and in Part Before the Denver and Arapahoe County Medical Society, Denver, Colo., March 8, 1898. By John W. Hill, C. E., Cincinnati, O. Printed for private circulation. Paper; 6 × 9 ins.; pp. 32; tables.

This pamphlet makes available Mr. Hill's latest ideas and information on this important subject. It contains much interesting and valuable material.

NEW TESTS OF CERTAIN PUMPS AND WATER LIFTS USED IN IRRIGATION.—By Ozni P. Hood, Professor of Mechanics and Engineering at the State Agricultural College, Manhattan, Kan. No. 14, Water Supply and Irrigation Papers of the U. S. Geological Survey, Chas. D. Walcott, Director, Washington, D. C. Address the Director or Members of Congress. Paper; 6 × 9 ins.; pp. 89; one plate and 58 figures in the text; tables.

The first part of this pamphlet consists of descriptions of various types of simple lift pumps. Following this are descriptions and the results of tests of the Mark, Frizell, Van Voorhis and Cook pumps, and a discussion of the resistance to rotation offered by various crank-driven pumps. After this a few bucket and other forms of water lifts are described. The whole is amply illustrated and appears to be clearly written.

SANITARY CONVENTION at Detroit, Mich., Dec. 9 and 10, 1897. Supplement to the Report of the Michigan State Board of Health for the Year 1898. Paper; 6 × 9 ins.: pp. 160. Henry B. Baker, Secretary, Lansing, Mich.

Among the papers in this pamphlet the following may be named: "Streets and Alleys and Their Relation to the Public Health," by John McVicar, Detroit; "Typhoid Fever and the Water Supply of Detroit," by Gardner S. Williams, Detroit; "Bicycling, from Social, Business and Healthful Standpoints," by Theo. R. MacClure, Lansing. The paper by Mr. Williams contains a very interesting account of an abnormal increase in the deaths from typhoid fever in Detroit in 1892, which he believes was connected with dredging near the outlets of the sewers of Port Huron and dumping the material removed in the St. Clair River. Estimates indicate that the time required for the infected river water to flow to Detroit would be from 6 to 12 days. The number of deaths from typhoid fever in Detroit in 1892 was 209, or 19.9 per 10,000 living. In the other eight of the nine years from 1889 to 1897, inclusive, the greatest number of deaths occurred in the year following the outbreak named, being 97, or 3.95 per 10,000. In 1897 only 31 deaths, or 1.1 per 10,000, were reported.

TRADE PUBLICATIONS.

(The standard sizes for pamphlets and trade catalogues recommended by all the principal engineering societies of the United States are: 3 1-2 x 6 ins.; 6 x 9 ins.. and 9 x 12 ins.)

STEAM AND HYDRAULIC PACKING.—La Favorite Rubber Mfg. Co., Paterson, N. J. Pamph.; 4¾ × 7½ ins.; pp. 31.

A descriptive list of rubber compound packings for boilers, pipes, etc., and other rubber specialties.

SMALL ENGINES AND BOILERS.—Sipp Machine Works, Paterson, N. J. Pamph.; 6 × 9 ins.; pp. 40.

Engines and boilers from ¼ to 2 HP. are illustrated in this catalogue; also castings for model engines for amateurs, students, etc. The Weed gas engine, and the Weed water motor are also illustrated.

MOTOR SUSPENSION—THE PATENT SITUATION.—The Walker Co., Cleveland, O.

The circular describes the points of difference between the General Electric method of suspending motors on electric cars and that of the Walker Co., with special reference to the patent litigation between the two companies.

PUMPING ENGINES.—Battle Creek Steam Pump Co., Battle Creek, Mich. Paper; 6½ × 7¼ ins.; pp. 12 and 4.

The larger of these pamphlets contains a description of the Marsh deep-well engine, with lists of sizes and prices, and tables of capacity. The smaller pamphlet describes the Marsh sinking pump for sinking or recovering shafts and for general mining work.

BALDWIN LOCOMOTIVE WORKS.—Burnham, Williams & Co., Philadelphia, Pa.; pamph, 9 × 6 ins.; pp. 32; illustrated.

This pamphlet contains a brief description of the Baldwin Locomotive Works, illustrated by numerous half-tone engravings from photographs taken in and about the offices and shops.

ELECTRIC RAILWAY MOTOR SUSPENSION CASE.—Pamph.; 6 × 9 ins.

This pamphlet gives the full text of Judge Buffington's opinion in the case of the Sprague Electric Railway & Motor Co. vs. The Steel Motor Co., filed in the U. S. Circuit Court, Western District of Pennsylvania, July 12, 1898.

GRAPHITE AS A LUBRICANT.—Joseph Dixon Crucible Co., Jersey City, N. J. Pamph.; 5 × 7 ins.; pp. 32.

The contents of this pamphlet are chiefly the same as those of the 1897 edition, with a few additions. One of them is an account of the use of graphite for lubricating gas engine cylinders, and another describes an oil pump for feeding graphite into cylinders.

CHAPSAL'S PATENT ELECTRO-PNEUMATIC BRAKE.—The Miller, Du Brul & Peters Mfg. Co., 507 East Pearl St., Cincinnati, Ohio.

This pamphlet describes a French invention, consisting of an electric attachment to any ordinary air brake, by means of which the valves are operated by electricity. It is said that this invention is meeting with some favor on French railways, which is another example of the fondness for complicated machinery which is a noticeable feature of French mechanical engineering. We feel entirely safe in saying that no American railway manager could be induced to add the complications of electric attachments of any sort whatever to the air brakes on his rolling stock.

AIR COMPRESSORS.—The Ingersoll-Sergeant Drill Co., 26 Cortlandt St., New York. Catalogue No. 32. Pamph.; 6 × 9 ins.; pp. 96.

This is an illustrated description, with lists of sizes, etc., of the air compressors built by this well-known firm. It contains much useful information on compressed air, which should be in the hands of every engineer who is interested in the subject.

ELECTRIC MINE HAULAGE.—Baldwin Locomotive Works and the Westinghouse Electric Mfg. Co., Philadelphia, Pa., or Pittsburg, Pa. Pamph.; 6 × 9 ins.

This is a neat pamphlet, briefly describing a new form of electric locomotives for mine service in which a number of improvements have been introduced. A table is included giving the general dimensions for sizes from 20-HP. to 150-HP.

HYDRAULIC MACHINERY.—Chambersburg Engineering Co., Chambersburg, Pa. Catalogue No. 23. Pamph.; 6 × 9 ins.; pp. 16.

The machinery illustrated in this catalogue comprises hydraulic cranes, accumulators and riveters, in different styles. The company makes a specialty of designing and building special machines to order, and also builds steam engines of several kinds.

GASOLINE LEAD-MELTING FURNACE.—Wm. E. Virtue, 59 Pennsylvania Ave., Newark, N. J. Paper; 3½ × 6 ins.; pp. 6; illustrated.

This pamphlet describes a lead-melting pot mounted above a gasoline burner. The furnace is made in several sizes. Convenience and economy of time and fuel are claimed for the device, which is said to be in use in Newark, Washington and other cities.

GASOLINE ENGINES.—Waterous Engine Works Co., St. Paul, Minn. Pamph.; 9 × 6 ins.; pp. 19.

The engine described in this catalogue is of the horizontal type. It is built in many sizes. A combined gasoline engine and pump is illustrated, the pump being driven from the engine shaft through spur gearing. A gasoline fire engine is also shown. It appears to be suitable for the fire service of small villages.

CENTRIFUGAL PUMPS.—The Lawrence Machine Co., Lawrence, Mass. Catalogue No. 8. Pamph.; 8 × 5 ins.; pp. 48.

This pamphlet contains lists of centrifugal pumps in a variety of styles, both vertical and horizontal, driven by belt, steam engine or electric motor. Sies up to 60 ins. are listed. On the cover the word pumps is spelled pvmps. This fad of using a V for a U should be left to the architects, and they ought to be ashamed of it.

CONSTRUCTION NEWS.

CONDENSED LIST OF CONTRACTS PENDING WITH DATE OF OPENING BIDS.

Bids to be opened.	Work.	Place.	See Eng. News.

Advertised, Engineering News, July 21.
No date. School building, Fresno, Cal. ....July 28

RAILWAYS.

ABBEVILLE.—Chas. R. Corbett and George Forrest have been awarded the contract for the construction of four miles of railway between Abbeville, La., and the Caffrey sugar refinery, at a cost of about $12,000. Seven miles more are still to be contracted for.

ATLANTIC & DANVILLE.—S. P. Daniel, Virgilina, Va., writes us that he has been placed in charge of a field party for the purpose of making surveys for an extension of the line of this railway to the copper mines in Virginia and North Carolina, near Virgilina, Va.

BALTIMORE & OHIO.—The receivers of this road have decided to improve the grades on that portion of the third division lying between Altamont, the top of the 17-mile grade, and Terra Alta, where the Cranberry grade begins to descend. The line passes through Deer Park and Oakland, and crosses the Allegheny Mountains, where the grades are short and choppy, some being 80 to 85 ft. to the mile. Work is now in progress at No. 58 cut, the grade being reduced from 81 to 42½ ft. per mile. It is expected that the cutting down of this grade will enable the train load to be increased from 1,000 to 1,300 tons on east-bound trains. One mile of the roadway will be lowered and it is expected that the work will be completed by the middle of October. R. M. Sheats, Div. Supt., Grafton, W. Va.

BOOMER COAL & COKE CO.—It is reported that this company will build an extension to its new mines up Boomers' Branch, about 20 miles from Charleston, W. Va. Clifford Buxton, Toledo, O., Ch. Engr., Ohio Central R. R., may be addressed.

CEDAR RIVER.—Saml. Crawford, David E. Crawford and Earl H. Crawford are reported to have bought 53,000 acres of land in Delta and Menominee counties from the Spalding Lumber Co., including the mills and docks at Cedar River, Mich., for $160,000, and will build a railway from the latter place to some point on the Chicago & Northwestern Ry., about 27 miles, in order to market about 300,000,000 ft. of standing timber on these lands.

CINCINNATI NORTHERN.—This road will be extended to Jackson, Mich., according to a press report. Surveys are now being made. R. L. Read, Cincinnati, O., Ch. Engr.

CENTRAL MICHIGAN.—The bonds of this road have been sold and work on the proposed extension from Pioneer, O., to Grand Rapids, Mich., will be commenced at once, according to report. J. W. Boynton, Pres. and Treas., Grand Rapids.

CHICAGO GREAT WESTERN.—It is reported that this road will be extended to Omaha, Neb., via Mason City and Story City, and that surveys are now being made on three divisions of the proposed line. H. Fernstrom, St. Paul, Minn., Ch. Engr.

CLEARFIELD SOUTHERN.—A. W. Lee, Pres., writes us that the surveys for this road, the incorporation of which was noted in our issue of July 14, have been nearly completed, and the right of way and capital have been secured. The road will run from Belsena Mills, where it will connect with the Pennsylvania R. R., to Clearfield Bridge, a station on the Beech Creek R. R., 15 miles. Saml. Brugger, Fleming, Pa., Ch. Engr.

EAST CAROLINA.—The directors of this railway, the incorporation of which was noted in our issue of July 14, have resolved to issue $20,000 in bonds to run for 20 years, at 6%, to be secured by a first mortgage and deed of trust on the entire property. Pres. Henry Clark Bridges, Tarboro, N.C., may be addressed.

FAIRCHILD & NORTH EASTERN.—J. W. Gorman, Greenwood, Wis., has received the contract to build an extension to this road eastward, according to report. Ch. Engr., G. W. Godfroy, Fairchild, Wis.

GALVESTON, LAPORTE & HOUSTON.—This road is reported to have been bought by the Chicago, Rock Island & Texas Ry., through Geo. C. Holt, Woodstock, Ont., and will develop a through line to the Gulf. S. B. Hovey, Vice-Pres. and Gen. Supt., Fort Worth, Tex.

GUADALUPE VALLEY.—The work of grading this new road, which will run from O'Connorsport to Austin, Tex., via Victoria, Yakum, Gonzales and Bastrop, is now going forward rapidly and track laying will soon begin. A branch will be built from Gonzales to San Antonio, via Seguin. Col. Uriah Lott, Victoria, Tex., may be addressed.

HAWTHORNE & BLANCHARD.—F. Weyerbauser, Chippewa Falls, Wis., is President, and E. B. Banks, Superior, Wis., is Chief Engineer of a proposed line of steam railway, which will be built from Hawthorne to Blanchard, 13 miles. Right of way is now being secured and contracts will be let probably this week.

IDAHO.—Grading has been completed for the Idaho R. R., 17 miles long, which will run from Cupun to Ballords. Pres., D. M. White, Lewiston, Idaho; Ch. Engr., C. A. Tush, Huntington, Ore.

LEADVILLE, SOUTH EVANS & MOSQUITO PASS.—Surveys have been completed for this road, which will be 10 miles long, running to a number of important mines. Dan. Vaughn, Leadville, Colo., may be addressed.

LEHIGH VALLEY.—Chas. E. Webster, Ch. Engr., South Bethlehem, Pa., informs us that no extensions to this road are projected at present, but a third track is being constructed from Greens Bridge, near Phillipsburg, N. J., to Muse Tunnel, 9.3 miles, of which about three miles are already completed. A number of new modern steel bridges and replacing old iron bridges. Changes in some of the shops are contemplated, but the plans have not yet been prepared.

LITTLE ROCK & MEMPHIS.—It is reported that the Choctaw, Oklahoma & Gulf R. R. proposes to acquire the Little Rock & Memphis R. R. at the foreclosure sale, Oct. 25, and after reorganizing it as the Choctaw & Memphis, with $3,500,000 capital, will extend the eastern terminus to Little Rock, Ark., 130 miles. R. Fink, Little Rock, Receiver, Gen. Mgr., Ch. Engr., and Pur. Agt.

LOUISIANA & NORTH WEST.—J. D. Beardsley, Lessee and Gen. Mgr., Gibsland, La., writes us that 36 miles of the road have been finished from Bienville, La., to Homer, La., and 36 miles more from Homer to Magnolia, Ark., are under construction. It is expected that the road will begin running next month, at which time 78½ miles of the 200 miles projected, will have been completed. Pres., J. C. Case, St. Louis, Mo.; Ch. Engr., Wm. Washburn, Gibsland, La.

MEXICAN SOUTHERN.—Jas. R. Progue, C. E., Oaxaca, Mex., states that this road will be extended from Oaxaca to Minatlan, Mex. T. A. Corry, Puebla, Mex., is resident engineer.

MISSOURI PACIFIC.—It is reported that this road has acquired the Atchison & Pike's Peak R. R., 100 miles long, comprising the Central Branch of the Union Pacific Ry., extending from Atchison to Waterville, Kan. Ch. Engr., J. W. Way, St. Louis, Mo.

NELSON & BEDLINGTON.—Contracts will be let and construction begun within a short time, according to report, on the Nelson & Bedlington Ry., which is projected from Bonner's Ferry, Idaho, to Kushkonook, B. C., 50 miles. Cyrus R. Bunn, Spokane, Wash., is interested.

NEW CUMBERLAND & PITTSBURG.—This company has been incorporated, with $400,000 capital, by Jas. McCrea, Pres.; Jos. Wood, J. J. Brooks, John W. Renner and E. B. Taylor, all of Pittsburg, Pa., to build a steam railway, 16 miles long, between West Virginia and Phillipsburg, Pa.

NEW YORK, WYOMING & WESTERN.—Four field corps under Edw. L. Jenks are engaged in making surveys for this proposed road, which will carry nothing but coal, and will run from Scranton, Pa., to New York. It is estimated that the road will cost less than $10,000,000, and it is hoped to complete it this year. The officers are: Pres., E. B. Sturges; V.-Pres. and Gen. Mgr., L. A. Watres; Secy., Thos. E. Jones; Treas., Thos. H. Watkins; Ch. Engr., Edw. L. Jenks.

NORFOLK & WESTERN.—J. M. Barr, Roanoke, Va., V.-Pres. and Gen. Mgr., writes us that his company does not contemplate the construction of a line from Winston to Charlotte, N. C.

PITTSBURG & LAKE ERIE.—It is reported that this company has purchased 35 acres of land from the United States Glass Co., Glassport, Pa., and will lay tracks on it for a new yard to hold 500 coal cars. It is also said that the company contemplates an additional purchase of 25 acres, on which it will build a round-house and 24 dwellings for employes. L. H. Turner, Supt. Motive Power and Equipment McKee's Rocks, Pa., may be addressed.

RACQUETTE LAKE.—A new railway is projected from Clearwater, N. Y., to Racquette Lake, N.Y., connecting with the Adirondack Ry., at the former place. The road will be about 19 miles long. Dr. W. Seward Webb, New York, President of the St. Lawrence & Adirondack R. R., is the chief promoter.

RIO GRANDE WESTERN.—It is stated that an extension to this road is projected from Ogden to the Pacific Coast and south through California, possibly into Mexico. D. C. Dodge, V.-Pres. and Gen. Mgr., Denver, Colo.

SAN ANTONIO, LLANO & NORTHERN.—Surveys for this proposed railway from San Antonio to Llano, Strawn and Thurber, have been completed from Strawn to Llano, 140 miles, and construction will begin at once on the northern end of the line. The road will connect with the Texas & Pacific Ry., at Thurber Junction, and will be in all 330 miles long. Geo. W. Angle, Gen. Mgr., San Antonio, Tex.

SAINT JOSEPH & GRAND ISLAND.—An extension to this road will probably be built from Severance to Highland, Kan., seven miles; $200,000 in bonds have been voted by the latter town for this purpose. Gen. Mgr., W. P. Robinson, Jr., St. Joseph, Mo.

SANTANDER.—J. Ed. Buckley, of the La Compania de Ferrocarril de Santander, writes us that this company has been organized under the laws of the United States, for the purpose of building and operating a steam railway from Puerto Wilchess, on the Magdalena River, Colombia, to Bucaramanga, the departmental capital, 90 miles. The route will be from the Magdalena Terminal to Puerto Wilchess, 38 miles east, across the Magdalena Valley, to Puerto Santos, thence easterly up the River Libreja to las Bocas de Oro and Jeron (Pop. 9,000), Piedecuesta (Pop. 12,000), Florida (Pop. 5,000), terminating at Bucaramanga (Pop. 35,000). A branch 10 miles long will be built up the River de Oro, from las Bocas de Oro, to Rionegro (Pop. 12,000), the trading center of the coffee district, in which, it is stated, $12,000,000 in gold has been invested; another branch, 12 or 15 miles long, will be built due north from Bucaramanga to the gold zone, La Baja y Vetas, in which there are about 200 locations and one well developed mine. The line will be narrow gage, with a maximum grade of 2½%. A preliminary survey has been run through the country by Dr. Abelardo Ramos, but American engineers will make the final location. About 90% of the right of way is provided for. The contract price between the Colombian government and the grantee, Mr. Buckley, is $5,000,000 gold for building and equipping the road, and he receives 6% first mortgage 50-yr. gold bonds, secured by the road and its franchises. The government guarantees the interest on the bonds for 20 years, and for that purpose stipulates that 5% of the custom revenues of the nation, about $10.000,000 gold, shall constitute said guarantee fund. The present earning capacity of the road is stated to be $450,000 gold a year from the commerce and general transportation, and with the line completed to Bucaramanga the mines, it is expected, will furnish about $250,000 more. This concession gives the grantee the right to operate, in conjunction with the railway, a line of steamboats on the River Magdalena and steamships, on the ocean, between Cartagena or Puerto Savinella, with an American port on the Gulf or Atlantic coast, thus enabling the company to give through bills of lading from any American city to the interior of Colombia. The company also receives 150,000 acres of hard wood, coffee and rubber lands. J. E. Buckley, 1906 Pacific Ave., Spokane, Wash.; Dr. Ramon Guerra Azuola. Colombia, S. C., Gen. Counsel for Colombia.

SANTIAGO DE CUBA.—D. D. Vanaken & Co. have been awarded the contract to build docks and a short railway line at Santiago de Cuba, for the United States government, to be used in the handling of troops, according to report.

SIOUX CITY, CHICAGO & BALTIMORE.—The surveys for this proposed line have been completed to St. Louis, Mo. Ch. Engr., L. F. Wakefield; Pres., T. P. Gere, both of Sioux City, Ia.

SKAGWAY & LAKE BENNETT.—The narrow-gage locomotives and freight cars for this road have been shipped from Seattle, Wash., to Skagway, Alaska, according to report.

WISCONSIN & MICHIGAN.—It is reported that this road will be extended to Iron Mountain, Wis. Pres. and Treas., S. M. Fischer; Ch. Engr., A. M. Kinsman, both of Chicago.

STREET AND ELECTRIC RAILWAYS.

BERLIN, N. H.—A hearing was to be granted July 27 by the railroad commissioners on the question of the proposed electric railway from this city to Gorham, five miles. The capital stock of the company is $15,000, and the directors are: C. P. Day, L. J. Cote, A. M. Stahl, A. M. Clement, C. C. Gerrish, W. H. Paine and G. O. Holt

LACONIA, N. H.—The Laconia St. Ry. Co. will equip its road with electricity at once, taking the place of horses, and will extend the line over the new road to The Weirs in the spring. Pres., A. G. Folsom; Secy. and Treas., Edmund Little.

PORTSMOUTH, N. H.—Bids are asked until Aug. 2 by the Portsmouth & Dover Electric St. Ry. Co. for the construction of its power house at Noble's Island. Right of way has all been secured and the work of laying the rails will begin this week. Mr. Thompson, of the Boston & Maine R. R., is the engineer.

MONTPELIER, VT.—The directors of the Montpelier St. Ry. Co. have decided to build an addition to the car barn and an office for the superintendent, work on which will be commenced at once. The tracks will be extended on Main St., from College St., making a belt line. Supt. Smith may be addressed.

MONTPELIER, VT.—The local correspondent for the Burlington "Free Press" states that it is quite possible, as such a favorable report has been made on the building of the electric road between this city and Warren, that action will at once be taken by the different towns along the route so that work may be commenced as soon as possible, and it is hoped that it will be begun inside of two months, as much interest is taken in the project and the people are willing to help the matter along. Montpelier will soon be a railway center.

CLINTON, MASS.—The Clinton, Hudson, Maynard & Concord St. Ry. Co. has been granted a franchise to build an electric road in this city which must be completed within a year.

CONCORD, MASS.—The voters of this place, at a meeting July 23, decided not to require electric wires to be placed underground, in order, it is said, not to keep out of the town an overhead system of electric cars for which there has been considerable agitation.

NEW BEDFORD, MASS.—The board of public works has granted a franchise to the New Bedford, Middleboro & Brocton St. Ry. Co. to build an electric railway in this city, application for which was noted in our issue of July 14, which prohibits its doing a local business. Abbott P. Smith is interested.

HARTFORD, CONN.—The Hartford St. Ry. Co. is pushing work on its new auxiliary power house and hopes to have it completed and in running order by the middle of September. Pres., E. S. Goodrich; Secy. and Treas., Danl. R. Howe.

STAMFORD, CONN.—The electric branch line from Stamford to New Canaan, eight miles, of the Consolidated R. R., was opened July 17. The cars of the Stamford St. R. R. are being used until the arrival of the new cars and the route is the same as that of the former steam road, which is thus done away with.

ALBANY, N. Y.—A meeting of citizens was held July 22 to petition the Albany Ry. Co. to construct a trolley line on Second and Delaware Aves. to connect with the Pearl St. and Pine Hills lines. Henry F. Snyder, Robert Scott, Fred. Myer, August Whitman, John J. Lanahan, Ernest Decker, George Krank and Alderman Kapps, ex-officio, were appointed as a committee to report on a plan.

BROOKLYN, N. Y.—The railroad commissioners have granted permission to the Nassau Electric R. R. Co. of this borough to increase its capital stock from $6,000,000 to $15,000,000, for the purpose of canceling its obligations on lines leased to the company.

BUFFALO, N. Y.—The Crosstown St. Ry. Co. has made application to extend its lines.——The board of works has approved the plans reported in our issue of July 14 to have been filed by the Buffalo Ry. Co. for the enlargement of its conduits on Niagara St. Twelve ducts of brick tile will be added to the present six, which will be scraped, at a cost of $12,000, from Porter Ave. to the Square. H. H. Littell, Mgr., may be addressed for particulars.

CLINTON, N. Y.—The Sanquoit Valley Electric R. R. Co. has asked the board of trustees for a franchise to build a street railway in this village. A hearing will be granted on the application Aug. 3. The company has obtained the right of way between here and New Hartford, according to report.

FULTON, N. Y.—O. C. Breed, civil engineer, is making surveys for a proposed line of electric railway to be built from this place to Oswego Falls, according to press reports.

NEW YORK, N. Y.—Permission has been given by the railroad commissioners to the Kingsbridge Ry. Co. the North End St. Ry. Co. and the Fort George & 11th Ave. R. R. Co. to build and operate electric railways on the Boulevard and Kingsbridge Road, between Manhattan St. and Yonkers. Permission is granted on condition that but one set of tracks is laid on the Boulevard, where two routes are coincident.

SYRACUSE, N. Y.—The Syracuse, Skaneattles & Moravia R. R. Co. has asked for a franchise to build an electric railway in this city from the corner of West Fayette and Wyoming Sts. to the city line on the west. The franchise asked for by this company in Solvay, as noted in our issue of July 7, has not yet been granted, but probably will be as soon as the company has consented to the insertion of a clause requiring the road to be finished within a year. Pres., Wing T. Parker; Treas., T. W. Downing.

TROY, N. Y.—It is proposed to build an electric railway five miles long, to connect the Troy & New England R. R. with the Albany Ry. at its 3d St. terminus in Rensselaer. Surveys have been completed and work will soon begin, according to report.

ATLANTIC CITY, N. J.—The New Jersey Electric Ry. Co. has been incorporated to build an electric railway from Camden to this city. The road will be elevated in the terminal cities and the power stations will be at Port Republic and Gibbsboro. Pres., John J. Patterson, Altoona, Pa.

PATERSON, N. J.—The receivers of the Paterson Central Electric Ry. have concluded to dispose of the road as quickly as possible, according to press reports. Wm. Barbour and Charles Curie, Receivers.

PLAINFIELD, N. J.—Bids are asked until Aug. 4 by the board of chosen freeholders of Union county to construct and operate a street railway in North Ave., from Orchard St., Elizabeth, N. J., to Richmond St., in this city. S. Rusling Ryno, Clk., Elizabeth.

PITTSBURG, PA.—The car barn of the Consolidated Traction Co., located at Frankstown and Penn Aves., was completely destroyed by fire July 24, entailing a loss of about $175,000, well covered, it is stated, by insurance. Thirty-six cars were also destroyed. Pres., C. L. Magee; Secy., Jas. A. McDevitt; Treas., Geo. I. Whitney.

READING, PA.—It is stated that surveys for the proposed Boyertown & Reading Electric Ry. have reached Pleasantville, about midway of the line. Branch lines from Friedensburg to Limekiln, two and a-half miles, and from Griesemersville to Amityville, four miles, are also projected.——An electric railway is projected from this city to Bernville, 13 miles, according to report. Harrison Kalbach, Reading, may be addressed for particulars.

WILMINGTON, DEL.—The Chester Traction Co. is pushing work on the extension of its line from Chester to this city. The grading has been completed to Eagle St. and the rail laying to Flower St. on Seventh St. Supt. MacFayden may be addressed.——Edwin P. Williamson and Nicholas Spieles have been denied an injunction to restrain the Front & Union St. Ry. Co. from entering upon their land, according to report.

FREDERICK, MD.—The Frederick, Thurmont & Northern Electric Ry. has been organized to build an electric railway from this city to Gettysburg, Pa., via Lewistown, Thurmont and Emmitsburg. The road will be built as far as the latter place, 29 miles, and later will be extended to Gettysburg. Pres., L. V. Baughman; Engr., L. M. Lemley, Baltimore.

WASHINGTON, D. C.—It is reported that the City & Suburban R. R. Co., the new name of the allied lines of this city, has decided to issue $1,750,000 in bonds for the purchase of the Maryland & Washington R. R., at $700,000, and the Columbia & Maryland, at $698,000, the balance being used to retire bonds of the Eckington & Soldiers' Home R. R., absorbed by the City & Suburban. Pres., O. T. Crosby; Secy., Dana Stevens; Treas., S. C. Cooper.

WASHINGTON, D. C.—A street railway company to be known as the Washington & University Railroad Company has been authorized by Congress to build a railway from the Tenleytown road to the American University, and from there to the District line. D. D. Stone may be addressed.

FAIRMONT, W. VA.—A survey is reported to be in progress, under the charge of C. W. Fawcett for an electric street railway from Fairview to this place.

NEW ORLEANS, LA.—The New Orleans City & Lake R. R. Co. has finished and begun operating its electric line to West End, according to report.

CANTON, O.—Dr. J. B. Shank, of this city, is circulating a petition, according to report, requesting the Canton-Massillon Electric Ry. Co. to extend its line out Navarre St., from Market St. to Dueber Ave., and thence north and south to connect with the south and west lines of the road. Pres. and Treas., Wm. A. Lynch.

DAYTON, O.—The franchise of the Dayton & Troy Electric Ry. Co. has been revoked, according to report, as the company failed to begin construction within the specified time. The Dayton Northern Ry. Co. has made application for the franchise.——A press report states that the Dayton Rapid Transit Co. has been organized to construct an electric railway from this city to Xenia. J. W. Neff, Xenia, Vice-Pres.

DAYTON, O.—The Dayton & Northern Ohio R. R. Co. has been incorporated, with $10,000 capital, by Jas. Christy, Jr., H. E. Randall, W. C. Shepherd, F. J. J. Stout and C. E. Hoover, to build an electric railway from this city to Troy, via Chambersburg, Vandalia and Tippecanoe, according to report.

EATON, O.—It is stated that an electric railway is projected by Joel Steward and Dr. Satin, both of Gratis, and others, from this place to Middletown, via Gratis.

ANDERSON, IND.—The Union Traction Co., known as the Indiana Gas Belt Electric Ry., is reported to have purchased the Anderson Electric St. Ry. for $150,000 and an equal amount in notes. It is also stated that the plant of the Marion Electric Ry. will be purchased, including the line as far south as Summitville, as will be connected to the Anderson St. Ry., making a line 32 miles long, passing through Linwood, Alexandria, Jonesboro and Fairmount in addition to the other places mentioned. Pres., Treas. and Gen. Mgr., C. L. Henry.

BENTON HARBOR, MICH.—The right of way for the new electric railway from South Bend, Ind., to this place has been secured, according to report, and a water power will be developed and repair shop built at Berrien Springs. A dam 20 ft. high and 1,200 ft. long, capable of developing 8,000 to 9,000 HP. is proposed. John A. Russell, Detroit, is interested.

KALAMAZOO, MICH.—An electric railway is projected from this city to Battle Creek, according to report. It is said that Norton & Tunstall, 34 Wall St., New York, are the financial agents. Ch. Engr., Geo. S. Shafter, Philadelphia, Pa.

ALTON, ILL.—The Alton Ry. & Illuminating Co. intends extending its line from 6th and Alby Sts. to East Alton, according to report, and will also equip its Middletown line this fall with 70-lb. rails. Pres., Treas. and Gen. Mgr., J. F. Porter.

CHICAGO, ILL.—The Northern Electric Ry. Co. has asked the county board for a 50-year franchise to build an extension to its electric railway system from the western city limits to River Grove, 10 miles.——The Chicago & Fox Lake Electrical R. R. Co. has been incorporated by John W. Greene, Chas. E. Soule, Jr., Wm. A. Kawson, Stewart Spalding, Frank N. Willis and F. W. Pringle, all of Chicago, with $20,000 capital, to build an electric railway from Lake county, through McHenry county to the Wisconsin state line.

ROCKFORD, ILL.—The final survey for the Rock River Electric Ry., which will be built from this place to Oregon, Ill., via Byron, has been begun, according to report. It is hoped to have the road ready for operation this year; it will be 25 miles long. A water power will be secured at Oregon, where car barns and other buildings will be erected. Nagle, Holcomb &Co., Chicago, are said to have submitted a bid for the construction of the road, which is under consideration.

CENTERVILLE, IA.—A company is now being organized to build an electric railway between Iconium and Moravia, with extensions from the former place to Griffinsville and Confidence, and from Moravia to this place, making a system 22 miles long. It is said that the road will be operated by a storage battery system, and freight will also be carried.

KANSAS CITY, MO.—A resolution has been passed by the city council requesting the street railway companies to equip their cars with the latest and best forms of fenders. Alderman J. E. Jewell introduced the resolution. ——Permission has been granted the Metropolitan St. Ry. Co. to widen the gage of its tracks to 4 ft. 8½ ins., the standard of all the other lines in the city. The franchise of this company called for a gage under four feet. C. F. Morse, Pres. and Treas.

ST. LOUIS, MO.—An electric railway is projected from Bobringville to connect with the Southern Electric Ry., over a new 60-ft. road, which will be constructed from McGinnis Ave. to Union Road, one mile. The Southern Electric Ry. Co. is making extensive improvements to its power plant, costing about $130,000. A new 1,500-HP. engine, a 1,500-HP. dynamo and new Heine boilers will be installed, according to report. Pres., C. H. Spencer.

DALLAS, TEX.—The Dallas Consolidated Electric St. Ry. Co. has filed a mortgage for $800,000 to secure bonds which it will issue for the purpose of making extensions to its system.——J. P. Holland and Wm. H. McGrath, Vice-Pres. and Gen. Mgr., of the Dallas Electric Co., are reported to be interested in a system of electric railways which it is proposed to build in this state.

SPOKANE, WASH.—The United States Marble Co., owning quarries nine miles from Valley on the Spokane Falls & Northern Ry., has decided to build an electric railway to transport the material to the latter road. The officers of the company are: Pres., C. S. Edwards; Vice-Pres., John King; Secy., C. E. Mitchell; Treas., H. B. Allen.

REDLANDS, CAL.—Steps are being taken toward the transforming of the Redlands St. Ry., now operated by horses, into an electric road, and $50,000 in bonds will be issued for the purpose. J. H. Fisher, Gen. Mgr.

BRANTFORD, ONT.—R. L. Middleton, Ch. Engr., writes us that the construction of the Brantford & Woodstock Ry. will begin Sept. 15 and it is hoped to complete it by Nov. 30. There are 26 miles of single track connecting with the Canadian Pacific Ry., north of the town of Woodstock, and with the Toronto, Hamilton & Buffalo Ry., near the Brantford depot. The road will be equipped for both electricity and steam, and will be laid with 90-lb. steel T-rails. The only work to be let will be two miles of pile-driving along the river, a 500-ft. span steel cantilever bridge and three small steel bridges, all near the Brantford end of the line. The work in the Grand River at Brantford will be of an interesting character, owing to the treacherous nature of the river and its banks and the protection against the spring floods which devastate this part of the country. Mr. Middleton will be pleased to hear from any one who desires to furnish supplies.

PARIS, ONT.—G. H. Carroll, of this place, is reported to be projecting an electric railway from Paris to Ayr, connecting with the Canadian Pacific Ry., at the latter place. It will be operated by water power, for which purpose a dam will be built near here.

NELSON, B. C.—C. S. Drummond, representing the British Electric Traction Co., London, England, is said to have applied to the city council for a 30-year franchise to build an electric street railway in this city.

PARIS, FRANCE.—The Walker Co., Cleveland, O., is said to have received an order from this city for the equipment for 500 electric street railway cars. This includes 1,000 motors, 1,000 controllers, 500 trolleys and other details. The order will amount to over $500,000.

MILAN, ITALY.—La Societa Nazionale per Industrie ed Imprese Elettriche has been organized with $1,000,000 capital, in this city, to undertake the construction of electric railways and other electrical projects, according to report.

ROME, ITALY.—An electric street railway is reported to be projected in this city to run to Como and Lecco, 30 kilos. Prices will be asked for about Sept 15 for the necessary materials.

HONOLULU, HAWAII.—The Buffalo Ry. Co., Buffalo, N. Y., is reported to be interested in obtaining a franchise for an electric railway in this city.

ELECTRIC LIGHT AND POWER.

SANFORD, ME.—Press reports state that the Sanford Mills Co. is erecting a stone dam at the old falls of the Mousam River. The dam will be 450 ft. long, and in places 32 ft. deep. Its entire length rests on a solid ledge foundation. It is expected that the work will be completed Sept. 1. Work on the power station was begun this week. When completed, 2,500 HP. will be generated, part of which will be transmitted to the Sanford Mills, 8 miles distant, and part utilized by the Sanford & Cape Porpoise R. R. This electric road will pass within a half mile of the falls, with which it will be connected by a spur track.

WESTBROOK, ME.—Press reports state that the Westbrook Electric Light & Power Co. has made final arrangements for enlarging its power station at Lower Falls. Four 48-in. turbine water wheels and a 300-HP. two-phase Westinghouse generator have already been ordered. Supt. and Mgr., E. B. Newcomb; Engr., A. E. Winchester, South Norwalk, Conn.

SOMERSWORTH, N. H.—Mark A. Keains, Cy. Clk., writes us that this city will not establish a plant this year.

BRATTLEBORO, VT.—No information can yet be given with regard to the power plant at this place. Engrs., Butts & Crosby, 49 Pearl St., Hartford, Conn.

CONCORD, MASS.—Bids are asked until Aug. 5 for furnishing and installing two 125-HP. high-speed compound condensing engines, as stated in our advertising columns. The bids for boilers, heaters, etc., will be opened Aug. 1, as noted in these columns July 14. Stone & Webster, Engrs., 4 Post Office Square, Boston; Richard F. Barrett, Chn. Light Board.

DANVERS, MASS.—This place has voted to appropriate $5,500 for increasing the facilities of the electric light plant. Supt., T. J. Lynch.

BINGHAMTON, N. Y.—We are informed that the following bids were received July 19 for furnishing lighting fixtures. B. W. Mosher, Cy. Clk.:

D. J. Malone, Binghamton (accepted)	$2,850
Binghamton Electric Construction Co., Binghamton	2,186
Babcock Hardware Co., Binghamton	2,694
Gaylord & Gitapence, Binghamton	2,300
Cassidy & Son Mfg. Co., New York	1,865
Thos. P. Nightingale, Utica, N. Y	1,550

EAST SYRACUSE, N. Y.—M. C. Mulford is reported to have purchased the plant recently owned by Mrs. Knapp of Syracuse. Mr. Mulford has asked for a franchise to extend the lines and for permission to enlarge the plant.

SYRACUSE, N. Y.—Bids are asked until July 28 for furnishing and constructing plants for three school buildings. P. D. Cooney, Clk. Bd. Education.

CLINTON, N. J.—The electric light and steam power plant of the Clinton Electric Co. is to be sold at public auction Aug. 5. The advertisement describing this plant and announcing the sale is published on page xviii. of this paper.

WOODSTOWN, N. J.—It is reported that residents of this place are considering the question of organizing an electric light company.

DUQUESNE, PA.—Estimates, etc., for a municipal plant have been prepared by W. S. Taylor, Pittsburg. It is proposed to operate the plant in connection with the water-works.

LANSDALE, PA.—Bids are asked until Aug. 2 for furnishing and constructing a plant, to cost about $20,000. Clk., D. S. Schultz. Pres., L. M. Landis.

PHILADELPHIA, PA.—The Germantown Electric Light Co. has been granted permission to erect poles, wires, etc., for its lines in the 22d Ward.

COLUMBUS, GA.—G. Gunby Jordan, Treas. Columbus Power Co., writes us that bids will soon be asked for constructing the proposed plant; estimated cost, $200,000. The contract has already been let to the Holyoke Machine Co., Worcester, Mass., for furnishing the water-wheels and iron work. The plant will develop 10,000 HP. Des. Engr., W. C. Whitner, Columbus.

CULLMAN, ALA.—Jas. E. Clark, owner of the franchise of the Cullman Water & Lighting Co., writes us that the company is being organized. Bids for furnishing and constructing the plant will be asked about Sept. 1. The plant will have a capacity for 21 1,200 to 2,000-c. p. arc and 1,000 16-c. p. incandescent lights; estimated cost, $15,000.

NEW ORLEANS, LA.—Councilman Story has introduced an ordinance authorizing the council to receive bids for constructing a plant with a capacity of 2,000 arc, 2,000 c. p. and 5,000 16-c. p. incandescent lights. The plant is to be in operation Dec. 21, 1902, the date of the expiration of the contract with the Edison Lighting Co.

CANAL DOVER, O.—Leiser & Bowers are reported to have decided to build a light and power plant at their mills. It is said that if a sufficient number of subscribers can be secured light will be supplied to the houses and stores of the town.

McARTHUR, O.—Paris Horton, Pres. Bd. Trustees, writes us that bids will be wanted in about 30 days for furnishing and constructing a plant, to cost about $55,000. It will have a capacity for 20 2,000-c. p. arc and a large number of incandescent lights. The money has been appropriated, and is now in the hands of the trustees. Bids will be asked for furnishing machinery for a complete modern plant. Engrs., E. P. Roberts & Co., Cleveland, O.

MINERAL POINT, O.—Bids are asked until Aug. 22 for constructing an electric light and water-works plant, as stated in our advertising columns. Paul Voorhees, Engr., 1210 Guaranty Bldg., Buffalo; T. H. Edwards, Village Clk.

MINSTER, O.—Bids are asked until Aug. 16 for furnishing the materials and for constructing a plant. There will be required an 80-HP. engine, two 54-in. × 14-ft. boilers, a feed pump, three 40-K-W. dynamos, etc. Consult Engr., G. L. McKibben, Van Wert, O.; Clk., August Schunck.

BROWNSTOWN, IND.—G. B. Epperson, Anderson, Ind., has asked for a 20-year electric light franchise; estimated cost, $25,000.

EVANSVILLE, IND.—The committee has recommended that steps be taken at once to consider the advisability of building a city plant, to cost about $70,000. Mayor Akin may be addressed.

INDIANAPOLIS, IND.—Bids are asked by the board of trustees of the Indiana Institution for the Education of the Blind until Aug. 2 for furnishing and constructing a plant.

EATON RAPIDS, MICH.—A. R. Welch, Chelsea, Mich., has been granted a 5-year light franchise. It is said that 30 arc lights will be put in at once.

GRAND RAPIDS, MICH.—Nagle & Ball, New York Mutual Life Bldg., Chicago, Ill., have been directed by the council to prepare new plans for the proposed plant, after which new bids will be asked.

KALAMAZOO, MICH.—It is stated that W. A. Foote has purchased a three-fourths interest in the Kalamazoo Electric Co. from J. K. Wagner, Bush & Tate and B. A. Bush. The capital stock is $100,000. The plant will be increased and the service improved. Pres., W. A. Foote, Jackson, Mich.; Secy., S. S. Hulburt, Battle Creek; Treas., James B. Foote, Jackson. W. A. Foote is now interested in the Battle Creek, Jackson and Albion electric lighting plants. J. B. Foote writes us that no new work is contemplated.

YALE, MICH.—Bids are asked until Aug. 2 for furnishing and constructing a plant, as advertised in Engineering News, July 7. (Postponement from July 26.) E. F. Fead, Village Clk.

JOLIET, ILL.—The drainage board, Chicago, has let the contract for the power dam at Joliet, section No. 18, to Gahan & Byrne, Chicago, at $161,791. This contract includes the replacing of dam No. 1 at the present site for $17,751. The proposition of the canal commissioners is to have the dam removed 250 ft. further down the stream, in order to create more power.

DES MOINES, IA.—Local papers state as follows: A new plant will be erected at the dam, foot of Center St., at once by the Des Moines Edison Electric Light Co., which owns the water-power plant by purchase from the Fort Wayne Co. The Edison company will put up a structure 70 × 52 ft., costing about $6,500. It will be equipped with machinery made by the General Electric Co., Schenectady. N. Y. The entire plant will cost from $40,000 to $50,000. The plant is designed for water power. Three wheels which have been in the river since the mill burned six years ago will be utilized, but two new wheels, larger and better, will be put in also. The contract for building has been let to Chas. Weitz & Sons, of this city. One section of the building, 40 × 52 ft., will be erected first and equipped, then the other section. The present steam plant will be moved to the building at First and Chestnut Sts. Mgr., R. H. Fraser.

FOSSTON, MINN.—Fairbanks, Morse & Co., St. Paul, have been awarded the contract for constructing a plant and water-works, at $15,500.

AUBURN, NEB.—C. S. Hull, Cy. Clk., writes us that O. H. Kilburne will put in the proposed plant. It is probable that he has already bought the machinery.

ABILENE, KAN.—Jacob Brown is reported to have applied for permission to operate a plant for lighting the town, the power to be secured from his mills, two miles south of the town.

TISHOMINGO, IND. TER.—Press reports state that the company that has proposed to dam Pennington Creek two miles above Tishomingo has the estimates made on putting in a dam to furnish about 3,000 HP. It is likely that work will be begun soon. The dam proposed will furnish enough power for all kinds of milling machinery, a small electric light plant in the future if the town needs it, and a small system of water-works.

IDAHO FALLS, IDAHO.—Geo. Chapin, Chn., writes us that the question of issuing bonds for the purchase of the plant and water-works will be voted upon Aug. 9. Nothing further will be done until the bonds are sold.

LOS ANGELES, CAL.—The contract for street lighting has been awarded to the Los Angeles Lighting Co., at $6.50 a lamp a month. This is the bid which contemplates the maintenance of the tall mast system with 640 lamps lighting the city, each lamp to be of 2,000 c. p. This will cost the city $4,160 a month—an increase over last year's monthly payments of $16. For this price the city will get 180 more lamps than it has at present. Under the new contract, which goes into effect Jan. 1, the city will have lights all night and every night, where now it has but a half night service and no lights on moonlight nights.

BARRIE, ONT.—The question of issuing $35,000 in bonds for a plant of 65 arc lights will be voted upon Aug. 15.

LONDON, ONT.—Bids are asked until Aug. 3 for furnishing and constructing a plant, as stated in our advertising columns July 21. Samuel Stevely, Acting Chn.; Ormsby Graydon, Cy. Engr.

NIAGARA FALLS, ONT.—It is reported that J. G. White & Co., 29 Broadway, New York, and Baltimore, Md., have been awarded the contract to build the proposed power plant and station on the Canadian side of the Falls.

SEBASTOPOL, RUSSIA.—Press reports state that a company was recently formed at Ougree, Belgium, to be known as La Societe de Traction et d'Electricite de Sebastopol. The new company has a capital of $400,000, and will acquire and work the central electric lighting station and the system of electric tramway in Sebastopol, South Russia. The company is to spend $300,000 in about three months, making purchases of machinery, track material and equipment. The parties sending the advices add that there is plenty of time for American manufacturers to put in their bids.

SHANGHAI, CHINA.—Bids are asked by F. S. Blackall, of Blackall & Baldwin, 39 and 41 Cortlandt St., New York, until Aug. 10 for furnishing and constructing a plant for this municipality, to cost about $40,000. There will be required two 100-K-W. alternators, switchboard, water-tube boilers, etc.

NEW COMPANIES.—Clear Creek Power Co., Denver, Colo.; $1,000,000; to generate power for lighting and other purposes in Clear Creek county; A. R. Specht, Boston; F. Rockefeller, M. A. Bradley, J. M. Henderson, D. R. Taylor, H. P. Malone and E. K. Tilloson, Cleveland.

Union Electric Co., 106 Market St., Camden, N. J.; $6,000, with full amount paid in; H. Geo. Lewis, Oak Lane, Pa.; Chas. J. Hart, Sharon Hill, Pa.; H. G. Kepler, Philadelphia; S. H. Richards, Bridgeport, N. J.

Kinderhook Power & Light Co., Kinderhook, N. Y.; $50,000; to furnish light, heat and power by electricity to Rensselaer, Troy, North Greenbush, East Greenbush, Schodack, Nassau, Bath, Castleton and Nassau; James Purcell, Valatie, N. Y.; James R. Hughes, James Hogan, John Ritz, Stuyvesant Falls, N. Y.; William D. Barnes, Brainard, Rensselaer county, N. Y.

BRIDGES.

BRATTLEBORO, VT.—Bids are asked until Aug. 6 for the purchase of $15,000 of 4% bridge bonds. Wm. H. Vinton, Chn. Bd. Selectmen.

NORTHFIELD, MASS.—Bids are asked until July 30 for constructing a bridge over the Connecticut River. Engrs., Edward S. Shaw, 12 Pearl St., Boston, and Clapp & Abercrombie, Ponds Block, Greenfield; Lyman A. Crafts, Chn. Comrs., Greenfield.

SALEM, MASS.—Bids are asked until Aug. 8 for reconstructing and widening the Forest River bridge. Engrs., Putnam & Riker, 251 Essex St.; E. B. Bishop, Chn. County Comrs.

BROOKLYN, N. Y.—Bids are asked until Aug. 4 for furnishing material and constructing the substructure for the bridge across Newtown Creek, from Grand St. to Grand Ave. John L. Shea, Comr., Stewart Bldg., New York.

JERSEY CITY, N. J.—Bids are asked until Aug. 4 for the purchase of $26,000 of 4% bridge bonds. E. W. Wooley, Clk. Bd. Freeholders.

NEW BRUNSWICK, N. J.—Bids are asked until Aug. 3 for the repair of two bridges. R. J. Dougherty, County Engr., 113 Albany St.

PATERSON, N. J.—Bids are asked until Aug. 2 for constructing two iron bridges and abutments in Pompton township and for an iron beam bridge in West Milford township. Geo. W. Botbyle, Clk. Bd. Freeholders.

JERSEY CITY, N. J.—The Jersey City Electric Light Co. has petitioned the street and water commissioners for permission to construct a trestle from the Pennsylvania Ry. to the Railroad Ave. plant.——The following local bids were received July 7 for constructing a steel viaduct over the Erie Ry. and the West Shore Ry. tracks. N. W. Wooley, Clk. Bd. Freeholders:

	With 146-ft. through span.	Without through span.
McGuire & Hall, 26 Cortlandt St., N. Y.*	$62,025	$49,755
Michael J. Curley	54,398	16,600
M. T. Connely	64,000	52,000
Sandford & Stillman	67,552	54,681
Fagin Iron Works	69,000	57,000
Palisade Construction Co.	64,030	55,900

*Accepted.

BUTLER, PA.—Bids are asked until Aug. 2 for masonry work on one bridge. H. E. Colter, Secy.

CHAMBERSBURG, PA.—A committee consisting of Messrs. Hoffeditz, Henderson and Gilbert have been appointed to arrange with the county commissioners for the construction of a bridge over Falling Spring at Kennedy Ave.

COCALICO, PA.—The county commissioners have decided to build a bridge over the Cocalico Creek at this place. The structure is to be of steel, 75 ft. in length and 16 ft. wide.

CONNELLSVILLE, PA.—The Pittsburg Bridge Co., Pittsburg, has been awarded a contract at $60,000 for constructing a new bridge over the Youghiogheny River, for the Youghiogheny Bridge Co.

MOSGROVE, PA.—A contract has been awarded to the Keystone Bridge Co., Pittsburg, for the construction of a $150,000 bridge over the Allegheny River, for the Buffalo, Rochester & Pittsburg R. R. Co. and the Allegheny & Western R. R. Co. The structure will be 1,600 ft. long, 25 ft. wide and contain 2,000 tons of steel. E. K. Morse, Engr., Pittsburg.

PITTSBURG, PA.—John Brunner, Cy. Engr., writes us that plans are nearly ready for the reconstruction of the South 10th St. bridge, to be 40 ft. wide, having two spans of 520 ft. and 375 ft., with two new piers. As no money has yet been appropriated the work will probably not be done this year. E. M. Bigelow, Dir. Dept. Pub. Wks.

WILKES-BARRE, PA.—Reports state that the county commissioners are in favor of a proposition to purchase the eight toll bridges, crossing the Susquehanna River, at a cost of about $400,000.

JACKSON, MISS.—Bids are asked until Aug. 9 for certain bridge construction, as described in our issue of July 14. (Postponement from Aug. 2.) Walter G. Kirkpatrick, Cy. Engr.

SPRINGFIELD, TENN.—Bids are asked until Aug. 5 for constructing a stone arch bridge across Black Branch. J. W. Bell, Chn. Com.

CANTON, O.—Reports state that a 100-ft. truss bridge will be constructed on South Cherry St. Wm. A. Reed, County Audr.

CLEVELAND, O.—Bids are asked until Aug. 19 for constructing the Willet St. viaduct substructure and masonry abutments. Geo. R. Warden, Dir. Pub. Wks.

CINCINNATI, O.—Bids are asked until Aug. 20 for constructing a bridge on the Riddle Road, in Springfield township. E. L. Lewis, County Audr.

HAMILTON, O.—L. A. Dillon, Engr., has submitted plans to the county commissioners for the proposed 400-ft. bridge over the Miami River at Wood St; estimated cost, $79,000.

HAMILTON, O.—The Toledo Bridge Co., Toledo, O., has been awarded a contract by the county commissioners at $8,450 for constructing a hoist bridge.

LEBANON, O.—Bids are asked until Aug. 22 for constructing a steel substructure on Caesar's Creek, according to reports. P. O. Monfort, Engr.

NORWALK, O.—Jno. Laylin, County Surv., informs us that the following bids were received July 16 for constructing a steel bridge; length, 105 ft.; width, 16 ft.; capacity, 200 lbs. per sq. ft.:

Iron Substructure Co., Columbus, O.	$1,500
Variety Iron Works, Cleveland	1,575
King Bridge Co., Cleveland	1,498
Canton Bridge Co., Canton	1,694
Toledo Bridge Co., Toledo	*1,710
W. H. Smith, Norwalk	**1,706
Penn Bridge Co., Beaver Falls, Pa.	1,780
Wrought Iron Bridge Co., Canton, O.	$1,197 to 1,597
Brackett Bridge Co., Cincinnati	1,289
Massillon Bridge Co., Massillon, O.	1,500
Virginia Bridge Co., Roanoke, Va.	1,506
Mt. Vernon Bridge Works, Mt. Vernon	$1,250 and 1,550
Milwaukee Bridge & Iron Works, Milwaukee, Wis.	2,020

*Low truss, $1,595; awarded contract for an eight-panel bridge. **Low truss, $1,570.

SHELBY, O.—The county commissioners have decided to construct a new stone or iron bridge to cost about $5,000. Mayor Green or Engineer Weddell may be addressed.

WOODSFIELD, O.—Bids are asked until July 29 for constructing a superstructure, 130 ft. long and 16 ft. wide, having a capacity of 125 lbs. per sq. ft. W. T. Wood, County Audr.

YOUNGSTOWN, O.—The question of constructing a viaduct to connect with Steelton, at an estimated cost of $75,000, is being considered.

HART, MICH.—It has been voted to construct a new bridge at a cost of $6,000.

GRAND DETOUR, ILL.—It is reported that the county commissioners have voted to appropriate $20,000 toward the construction of a bridge over Rock River; estimated cost, $40,000.

URBANA, ILL.—Bids are asked until Aug. 4 for constructing a highway bridge on masonry. Ira O. Baker, Engr., Champaign.

ALMA, NEB.—Bids are asked until Aug. 9 for constructing nine iron bridges. S. L. Roberts, County Clk.

ATCHISON, KAN.—Geo. S. Morison, Engr., Chicago, Ill., has prepared plans for the reconstruction of the bridge over the Missouri River, to cost about $60,000, for the Chicago & Eastern Bridge Co., according to reports. W. F. Guthrie, W. W. Guthrie and N. D. Todd, Atchison, may be addressed.

OREGON, MO.—Bids are asked until Aug. 2 for the construction and repair of certain bridges. C. G. Landon, County Comr.

ST. JOSEPH, MO.—The Chicago & Great Western Ry. Co. has offered to construct a $20,000 viaduct over the tracks at Grand Ave., in North St. Joseph.

DALLAS, TEX.—We are informed that the following local bids were received by the county commissioners July 19 for constructing a 150-ft. iron bridge on the Oak Cliff

pike road. C. E. Brown, Engr.: C. R. Lane, $1,647; J. T. Carter, $1,650; Topscott, $1,800; C. W. Olcott, 182 First Ave. (accepted), $1,900; Bryant & Marshall, $1,975; Brown & Dobney, $2,000; J. W. Fuller, $2,100; Geo. E. King Bridge Co., Des Moines, Ia., $2,490.

HEARNE, TEX.—An effort has been made by the citizens to have a new bridge built across the Brazos River at Port Sullivan, but the officials do not feel able to do more than have the old bridge repaired.

GOLDENDALE, WASH.—Bids are asked by the county commissioners until Aug. 4 for constructing a bridge across the creek.

ARBUCKLE, CAL.—Bids are asked by the county supervisors until Aug. 3 for constructing four bridges.

AUBURN, CAL.—Bids are asked until Aug. 2 for constructing a cable bridge across a fork of the American River. Wm. I. May, County Clk.

MARTINEZ, CAL.—Bids are asked until Aug. 1 for constructing an 85-ft. bridge over San Pablo Creek. F. L. Glass, County Clk.

UKIAH, CAL.—Bids are asked until July 30 for repairing two bridges. C. P. Smith, Chn. Bd. Supervisors.

BRANTFORD, ONT.—Several bridges will be required on the line of the new Brantford & Woodstock Ry., on which work will be commenced in September. The work will include a 500-ft. cantilever and three smaller structures. R. L. Middleton, Cy. Engr., Brantford.

BUILDINGS.

BOSTON, MASS.—Reports state that the following local bids were received July 14 for constructing a high school building. Thos. S. Stranger, Chn. Com.:

W. H. Keyes & Co., 17 Otis St., Boston	$259,943
Kerreno Driscoll, 17 Otis St.	253,952
Connery & Wentworth, 22 Pemberton Square	237,500
John L. Jacobs & Son, Herald Bldg.	237,400
Norcross Bros., 1143 Tremont Bldg.	237,263
James Fagan, 27 School St.	229,389
Meade, Mason & Co., 13 Exchange St.	226,950
James A. Colson, 90 Monumental St.	207,905

SPRINGFIELD, MASS.—Bids are asked until Aug. 1 for erecting and plumbing the Alden St. school building. Arch., F. R. Richmond, Masonic Bldg., Springfield; Chas. E. Brown, Chn. Com.

LOCKPORT, N. Y.—Bids are asked until Aug. 4 for erecting a hospital at the Niagara County Farm. Fred H. Krull, Clk. Bd. Supervisors.

MECHANICSVILLE, N. Y.—An extension of 40 × 70 ft. will be built on to the Methodist Episcopal Church.

NEW YORK, N. Y.—Reports state that J. D. Rockefeller will give $10,000 toward the construction of a Barnard College building, to cost $100,000.——Plans have been prepared by F. R. Comstock, Arch., for the erection of a church, on Fifth Ave. and 68th St., to cost about $100,000. Mrs. Laura Lathrop and Rev. Dr. Geo. Tompkins are interested.——Plans have been filed by Linton B. Matthews, 59 West 125th St., for two 5-story brick flat buildings on 3d Ave., near 173d St.; cost $50,000. Archs., Neville & Bagge, 217 West 125th St.; by Hubert S. S. Harde, 648 Madison Ave., for a 6-story brick flat building, on 80th St., near West End Ave., to cost $75,000. Townsend & Harde, Archs.; by Francis J. Schnugg, 1 East 94th St., for a 6-story dwelling on 158th St. and Boulevard Lafayette, to cost $90,000. Louis Entzer, Arch., 78 East 96th St.; by John Westervelt, 43 East 19th St., for an 8-story brick and stone flat building on 80th St., near West End Ave., to cost $300,000. Arch., Henry Anderson, 1180 Broadway; by William Hall and T. M. Hall, 31 East 74th St., for three 5-story dwellings on Riverside Drive, near 87th St., to cost $99,000. A. M. Welch, Arch., 503 5th Ave.; by the Harrison Realty Co., Harrison, N. Y., for an 8-story brick office building at 90 Prince St., to cost $90,000. Neville & Bagge, Archs., 217 West 125th St.; by Lowen Harde and S. Harde, 307 West 85th St., for a 7-story brick flat building, 102 × 51 ft., on 80th St. and West End Ave., to cost $175,000. Archs., Townsend & Harde, 29 East 19th St.

NEW YORK, N. Y.—Plans have been filed by Patrick H. Lynch, Arch., 642 West 128th St., for six 4-story brick dwellings, 16 × 47 ft., to cost $72,000, on 141st St. and Hamilton Place; S. Guidera, 26 East 118th St., for three 5-story brick tenements, on 168th St. and Audubon Ave., to cost $54,000. Arch., J. West Wagner, 407 Nostrand Ave., Brooklyn; by J. C. Lyon, 67 East 127th St., for eight 5-story brick and stone dwellings, on 74th St., near Park Ave., to cost $178,000. Archs., Buckman & Deisler.

NORWICH, N. Y.—An offer has been made to construct a jail building, at a cost of $14,000.

SYRACUSE, N. Y.—C. T. Snavlin will erect a $65,000 dwelling on South Crouse Ave.

ROCHESTER, N. Y.—Plans have been filed by John D. Lynn and J. J. Schubert for a theater building, 70 × 165 ft., to cost $80,000. Arch., J. Foster Warner.

TROY, N. Y.—The following bids have been received for masonry work in the construction of a school building at Third and Adams Sts.: William Ellis, $29,300; Charles Crowley, $28,965; James Dollard, $29,700; Timothy Casey, $27,995; William Behan, $31,042; James H. Morrissey, $29,500; Charles P. Boland, $28,154.

PATERSON, N. J.—Bids are asked until Aug. 1 for the purchase of $100,000 of 4% court house bonds. E. G. Edwards, Chn. Com., Paterson Savings Institution Bldg.

PITTSBURG, PA.—Plans have been accepted for the erection of a Roman Catholic church, at First Ave. and Kennedy St., to cost $150,000.

WILMINGTON, DEL.—Bids are asked until Aug. 8 for furnishing plans and specifications for the erection of a high school building on Delaware Ave. Wm. Turner, Chn. Com.

BALTIMORE, MD.—Bids are asked until Aug. 25 for the construction of the Wade Point lighthouse, N. C., as stated in our advertising columns. Lt.-Col. W. A. Jones, U. S. Lighthouse Engr., Baltimore.

DANVILLE, VA.—Bids will be asked about Sept. 1 for erecting the new Masonic Temple, to cost about $50,000. Arch., Frank P. Milburn, Charlotte, N. C.

WALHALLA, N. C.—Reports state that plans have been prepared by C. M. Guest, Arch., Anderson, for a bank building, to be erected for J. D. Verner.

ATLANTA, GA.—Bids are asked until July 29 for erecting a hospital building and stewards' quarters, at Fort Morgan, Ala. John Simpson, Chief Q. M., Atlanta.

JACKSON, MISS.—Bids are asked by the board of aldermen until Aug. 2 for constructing a 2-story brick addition to the school building at Oakley and Bloom Sts.

MEMPHIS, TENN.—A. J. Welch and J. H. Sullivan, Memphis, will present a petition to the railway companies for a new station, to cost about $170,000.

NASHVILLE, TENN.—Bids were opened at the office of the Louisville & Nashville Ry. Co., at this place, on July 25, for the erection of a new union station, to cost about $1,600,000.

NEWPORT, KY.—A fire in this place July 20 destroyed a saw mill and 17 dwellings, at a reported loss of about $100,000.

BELLEFONTAINE, O.—The fire committee has recommended an issue of $10,000 in bonds to erect a new 2-story brick building, at Columbus and Mad River Sts.

COLUMBUS, O.—Plans have been prepared by Yost & Packard, Y. M. C. A. Bldg., for a new Methodist Episcopal Church, to cost $30,000.

COLUMBUS, O.—Bids are asked until Aug. 23 for furnishing the material and for erecting a school building for the Ohio Institute for the Education of the Deaf and Dumb. Archs., Richards & McCarty, Columbus; J. W. Jones, Secy.

TOLEDO, O.—Bids are asked until Aug. 3 for furnishing the material and constructing a jail building. Arch., David L. Stive; Wm. M. Godfrey, County Audr.

LOGANSPORT, IND.—Bids are asked until Aug. 1 for constructing an 8-room school building. Arch., J. F. Alexander & Son, Lafayette; James D. McNitt, Trustee.

CHICAGO, ILL.—Contracts have been let by Richard E. Schmidt for the 10-story business block which Montgomery, Ward & Co. will erect at Michigan Ave. and Madison St., at a cost of $200,000; by D. H. Burnham & Co., for the fireproof office building for the Union Trust Co., at Pittsburg, to cost $150,000, and by Frost & Granger for a passenger station at Green Bay, Wis., for the Chicago & Northwestern R. R., to cost $15,000.

DANVILLE, ILL.—Bids are asked until Aug. 1 for furnishing the material and for installing a steam heating system at the National Home for Disabled Volunteer Soldiers. J. B. Birmingham, Treas., Danville; W. B. Franklin, Pres. Bd. Mgrs., Hartford, Conn.

HEYWORTH, ILL.—Bids are asked until Aug. 1 for building a brick school house. Arch., P. O. Moratz, 103 East Front St., Bloomington, Ill.; Secy., W. Delano.

OSHKOSH, WIS.—The Chicago & Northwestern Ry. Co. will construct a freight station, 400 ft. long, according to reports.

ST. PAUL, MINN.—Plans are being prepared by Bruchner & Jacobsen, Archs., St. Paul, for the Norwegian Lutheran Seminary building, to be erected at Hamline, to cost $50,000.

ST. PAUL, MINN.—M. J. O'Neil and August Wolentine have applied for permission to erect a 4-story apartment building, to cost about $60,000.

ST. JAMES, MINN.—J. B. Nelson & Co., Mankato, Minn., are reported to have been awarded the contract, at $25,468, for constructing the Park Hotel for M. K. Armstrong. Arch., Frank Thayer, Mankato.

ZUMBROTA, MINN.—Bids are asked until Aug. 5 for constructing a 3-story hospital building for the Lutheran Hospital Association. Arch., C. L. Grover; Chn. Com., R. V. Lund.

CRESTON, IA.—The Chicago, Burlington & Quincy Ry. Co. is about to commence the construction of a new station which will cost $50,000. W. C. Brown, Gen. Mgr., Chicago.

DES MOINES, IA.—Lafayette Higgins, Engr., 352 and 353 Good Block, Des Moines, is preparing plans for a low-pressure steam heating plant to be placed in University Place Church, Des Moines; work to be let soon.

AUBURN, NEB.—Nemaha county, it is reported, will again vote on the question of issuing $40,000 in bonds for a county court house.

DEADWOOD, S. DAK.—This city voted July 14 to issue $10,000 in bonds for a new school house, according to reports.

LISBON, N. DAK.—Bids are asked until Sept. 15 for remodeling and enlarging the court house, according to reports. T. J. Harris, County Audr.

JEFFERSON CITY, MO.—Surveys have been made by the Missouri Pacific R. R. Co. for a new passenger and freight station, to be 243 ft. long and 36 ft. wide. The contract will be let soon. E. Fisher, Engr. Bridges and Buildings.

HELENA, MONT.—Bids are asked until Sept. 13 for erecting a 3-story brick, stone and iron capitol building, to cost about $300,000. Archs., Bell & Kent, Merchants' Bank Bldg., Helena; Chn. Com., Robt. B. Smith; Secy., E. B. Kennedy.

ANACONDA, MONT.—Bids are asked until Aug. 8 for the purchase of $30,000 of 6% school bonds. E. J. Nadeau, Clk. School Trustees of District No. 10.

BUTTE, MONT.—It is stated that the school board will ask for new bids for building the new school house for East Butte, to cost about $28,600. The bids were given in our last issue.

COLORADO SPRINGS, COLO.—Steps are being taken for building a new First Methodist Episcopal Church, to cost about $50,000. Dr. Allen, Pastor; Messrs. Hallett and Simmons are on the committee.

DENVER, COLO.—It is reported that a 5-story brick and stone theater building, 100 × 200 ft., to seat 3,000 persons, is to be erected on 15th and Arapahoe Sts., to cost about $300,000. The Denver Tramway Co. is interested.

SPOKANE, WASH.—Bids are asked by the board of directors of school district No. 81 until Aug. 1 for constructing a 2-room brick school building. E. A. Thomas, Secy.

PORTLAND, ORE.—Bids are asked until Aug. 5 for furnishing plans and specifications for the erection of a court house. E. Hayter, County Clk.

FRESNO, CAL.—Bids are asked for the erection of a new school building. D. C. McDougall, Trustee.

OAKLAND, CAL.—The plans of Percy & Hamilton, Archs., for the new library building for the Sanford University have been accepted; cost, $150,000.

PALO ALTO, CAL.—Bids for construction of a library building and an assembly hall to be erected on the campus have been opened, and work will be begun at once. Estimated cost of the two structures is $280,000.

STOCKTON, CAL.—Bids are asked until Aug. 19 for erecting an administration building and two cottages on the grounds of the Preston School of Industry. Secy., B. T. K. Preston. Address J. W. Oates, Salz Bldg., Stockton.

LONDON, ONT.—Bids are asked until Aug. 1 for erecting a public school building. Herbert Matthews, Arch.

WATER-WORKS.

BREWER, ME.—Plans have been prepared by H. T. Sparks, Supt. Water-Works, Public Works Co., for a filter 50 ft. long to have a capacity of about 2,000,000 gallons of water a day. Other improvements to the works are also proposed.

BOSTON, MASS.—Bids are asked by the Metropolitan Water Board until Aug. 9 for making excavations for the North Dike of the Wachusett reservoir at Clinton (290,000 cu. yds. earth excavation), and also for laying 3,060 ft. of 48-in. pipe in the Brighton district, as stated in our advertising columns. F. P. Stearns, Ch. Engr.; W. N. Davenport, Secy., 3 Mount Vernon St.

NEWBURYPORT, MASS.—Bids are asked until July 30 for building a masonry foundation for a stand-pipe to be erected on the lot occupied by the present stand-pipe. C. C. Dame, Chn. Com.

NORTH ANDOVER, MASS.—Geo. M. Cole & Co., Lawrence, Mass., have been awarded the contract for building the new pumping station at $5,312.

SEYMOUR, CONN.—C. W. Blakeslee & Sons, New Haven, Conn., have been awarded the contract for building a reservoir and dam for the Seymour Water-Works Co. The stream selected as a supply is the Pine Bridge Brook. The water company has purchased 12 acres of land and the pond will contain about 10,000,000 gallons of water. The plans contemplate the erection of a larger dam for storage reservoir later on. Total cost is estimated at $50,000.

ALBANY, N. Y.—Bids are asked until Aug. 2 for laying 6 to 12-in. water mains in several streets. Supt., Geo. I. Bailey.——It is proposed to clean and improve the Bleecker reservoir.

HORSEHEADS, N. Y.—H. N. Sciple and others, of Philadelphia, Pa., have applied for permission to build works.

FORESTPORT, N. Y.—The Forestport Water Co. has been incorporated by Howard M. Fordham, of Buffalo, and James Gallagher, Jr., Albert Herrig, Richard J. Monahan, Charles O'Connor, Francis X. Salzman, William E. Syphert, of Forestport; capital stock, $10,000.

LANSINGBURG, N. Y.—Chas. A. Roemer, Village Engr., writes us that the proposed extension to the works will consist of a storage reservoir with a pipe line about 4½ miles long, connecting with the present works.

MILLBROOK, N. Y.—Estimates, etc., for gravity works have been submitted to the board of trustees; estimated cost, $15,000. F. H. Scrip, Village Clk., writes us that there is no prospect of the works at present. Population, 850.

MOUNT VERNON, N. Y.—The question of placing water meters in the buildings and houses supplied with water from the works of the New York Suburban Water Co. is being considered.

NORWOOD, N. Y.—The Norwood Water Co. has been incorporated with a capital stock of $15,000 by Philip J. Barry and H. E. Mandeville, of Hazleton, Pa.; Dix W. Smith, of Elmira, N. Y.; W. B. Berry, Henry H. Warren, William H. Cushman and Leon C. Ball, of Massena, N. Y. Further information in regard to this improvement may be found in our issue of last week.

OGDENSBURG, N. Y.—Local papers state that a contract has been let to the Stilwell-Bierce & Smith-Vaile Co., Dayton, O., through their representative in this city, A. H. Dalzell, for two 48-in. Victor waterwheels and other apparatus for the power pumps of the water-works.

PORT JERVIS, N. Y.—The Port Jervis Water-Works Co., it is stated, is about to make extensions to its works and also to increase the water supply.

TICONDEROGA, N. Y.—The water board is making surveys for a water main to Worcester Pond, a distance of 1½ miles, for an increased water supply. Engr., D. M. Arnold.

BRIDGETON, N. J.—It is reported that the council has voted to spend about $15,000 for building a new reservoir.

HAMMONTON, N. J.—A. H. Sutton, Pres. Bd. Water Comrs., writes us that nothing has yet been done by the council with regard to works. The next council will be held July 30.

JERSEY CITY, N. J.—Bids are asked until Aug. 1 for furnishing 90 dozen ⅝-in. stop cocks; 50 dozen ¾-in. stop cocks; 25 dozen 1-in. stop cocks; 6 dozen 1½-in. stop cocks; 10,000 lbs. of lead; 500 lbs. of solder. Geo. T. Bouton, Clk. St. and Water Bd.

MONTCLAIR, N. J.—A. W. Simpson, Secy. Montclair Heights Water & Land Co., writes us that the company was incorporated to supply water to the Acquackanonk township, particularly for the development of Montclair Heights. Arrangements have been made for a reservoir. Wells and water-works are not wanted yet as the company has a hot-air system which will be used at present. Engr., W. S. Bacot, 1 Broadway, New York.

SALEM, N. J.—Bids are asked until Aug. 12 for constructing a filter plant of 500,000 gallons capacity, and also for a steam pump of 1,000,000 gallons capacity, as stated in our advertising columns. C. Hungerford, Engr., 116 West 69th St., New York; C. W. Casper, Supt. W.-W.

BARNESBORO, PA.—Bids are asked until Aug. 15 for the purchase of $9,500 of 30-year bonds for the proposed new works, according to reports.

BRADDOCK, PA.—Bids are asked until Aug. 1 for furnishing and laying 10,300 ft. of 16-in. cast-iron water pipe and 3,370 ft. of 12-in. sewer pipe. Wm. Howat, Supt.

EVANS CITY, PA.—It is reported that this place has voted to issue $40,000 in bonds for works.

LANCASTER, PA.—The council is reported to have engaged Edmund Mather, Pres. Water Comrs., Harrisburg, Pa., to submit a report for a settling basin for a better water supply for this city. Mr. Mather writes us that he is not aware of any action having been taken.

LATROBE, PA.—W. A. Johnston, Supt. Latrobe Water Co., writes us that the company will issue $100,000 in bonds for the improvements to be made to the works, the contracts for which were let recently, as noted in our last issue. The total cost will be $125,000.

NAZARETH, PA.—Frank Kunkel, Secy. Nazareth Water Co., writes us that no appropriation has been made and no steps taken for the proposed increased water supply. It is probable that steps will be taken soon.

SHENANDOAH, PA.—The committee has decided to build a 30,000,000-gallon reservoir at a cost of about $16,000. The question is being considered of either securing an increased water supply or of purchasing for $200,000 the plant of the Citizens' Water & Gas Co. and consolidating it with the city works. Councilmen Bell and Straughn may be addressed.

WILKES-BARRE, PA.—The Commings Lake Water Supply Co. has been incorporated with a capital stock of $10,000, by C. Drymond, Frederick Cross, E. E. Hoyt, Kingston, Pa.; T. F. Ryman, Wilkesbarre; Thomas Wingert, Luzerne, Pa.

GEORGETOWN, DEL.—W. T. Tunnell writes us that there is no probability of the proposed works being built this year.

CUMBERLAND, MD.—Geo. A. Kean, Mayor, writes us that nothing has been done as yet in regard to securing a better water supply. It is hoped, however, that the matter will soon be disposed of by the council. It is stated that E. A. Wilder, New York, has submitted a proposition for a new method of water filtration to cost $38,000.

HARPER'S FERRY, W. VA.—This place is reported about to engage an engineer to look over the ground and report on the proposed works.

DAVIDSON, N. C.—The trustees of Davidson College have decided to build works to supply the town and college buildings. Pres., Rev. J. B. Shearer; Chn., Rev. W. J. McKay, Maysville, S. C.

COLUMBIA, S. C.—C. C. Wilson, Cy. Engr., has submitted plans, etc., for new works and a sewerage system to cost about $450,000. The reservoir and pumping plant will cost $250,000, and the distribution system $175,000. A. R. Stewart, Chn. St. Com., writes us that definite plans have not yet been decided upon.

MILLEDGEVILLE, GA.—It is reported that the American Pipe Mfg. Co., 112 North Broad St., Philadelphia, Pa., owner of the works at this place, has purchased the Moran spring for an increased supply. Secy., H. Bayard Hodge, Philadelphia.

ROME, GA.—The question of a filtration plant at the works is reported as being considered.

BRISTOL, TENN.—It is reported that the committee will soon ask for bids for furnishing deep-well and duplex pumps, two steel tanks, one of 20,000 and one of about 500,000 gallons capacity, etc. The deep-well pump will have a capacity of 250,000 gallons. The well for the supply has been drilled 1,200 ft., at which depth a flow of 180 gallons a minute was secured. Contractor, S. B. Geiger, Chicago; Chn. Com., J. D. Mitchell.

CINCINNATI, O.—Bids are asked until Aug. 2 for the purchase of $500,000 of 3½% water-works bonds. C. G. Roth, Clk. Bd. Trustees.——Louis Drach submitted the lowest bid at $91,902 July 22 for the masonry work, grading and excavating of the property where the new works will be located at California, O.

CRIDERSVILLE, O.—The question of building works is being considered, according to reports.

MARIETTA, O.—Bids are asked until Aug. 29 for furnishing and installing a 3,000,000-gallon pumping engine for the works. Pres., J. H. McConnell.

MINERAL POINT, O.—Bids are asked until Aug. 22 for constructing works, as stated in our advertising columns. Paul Voorhees, Engr., Buffalo, N. Y.; T. H. Edwards, Village Clk.

NEWARK, O.—Press reports state that Judge Jones on July 18 confirmed the appraisement of the Newark Water-Works Co. in the case instituted against the company by the Farmers' Loan & Trust Co., and ordered the water-works sold for not less than $9,000, plus the first mortgage of $225,000.

POMEROY, O.—Bids are asked until Aug. 10 for furnishing and constructing works for the Pomeroy & Middleport Water Co., 800 Broad St., Newark, N. J., as described in our advertising columns of July 14. Pres., Geo. MacDonald, Newark, N. J.; Engr., J. W. Ledoux, 112 North Broad St., Philadelphia.

BROWNSTOWN, IND.—G. B. Epperson, Anderson, Ind., has applied for a 20-year franchise to supply this place with water.

EVANSVILLE, IND.—Bailey, Koerner & Co., Evansville, submitted the lowest bid July 19 for constructing the new building, etc., for the water-works, at $61,676. The lowest bid for constructing a steel plate smokestack on a concrete and stone foundation was submitted by the same firm, at $6,386. Engr., Chas. Hermany, Louisville.

EATON RAPIDS, MICH.—The council has been petitioned to call an election to vote again on the question of building works.

LAKE CITY, MICH.—It is reported that the plant at this place owned by D. Reeder & Co. was destroyed by fire July 15.

LAWTON, MICH.—An election was held July 26 to vote on the question of issuing $9,500 in 5% bonds for works. H. C. Lammond, Village Clk.

CHICAGO, ILL.—Bids are asked until Aug. 3 for furnishing special castings for hydrants, valves and water pipe. L. E. McGann, Comr. Pub. Wks.

McLEANSBORO, ILL.—The council of this place is reported to have voted to issue $32,000 in bonds for the proposed works.

BLAIR, WIS.—Bids are asked until Aug. 1 for furnishing and installing works, to cost about $4,000. E. L. Immell, Village Pres.

TREMPEALEAU, WIS.—The question of building works to cost about $5,000 is being considered, according to reports.

FOSSTON, MINN.—Fairbanks, Morse & Co., St. Paul, have been awarded the contract for building the works and electric plant, at $15,500.

LAKEVILLE, MINN.—It is reported that this place will vote to issue $3,500 in bonds for works.

BALDWIN, IA.—Bids are asked until Aug. 2 for furnishing a steel water-tower, tank, pipe, 4-HP. gasoline engine, pump, etc., for the proposed works, to cost $5,000. Engr., Iowa Engineering Co., Weston Block, Clinton; Clk., J. H. Summers.

OGDEN, IA.—Fairbanks, Morse & Co., St. Paul., Minn., have been awarded the contract for building the works, at $4,367.

McPHERSON, KAN.—A. Bass, Cy. Engr., writes us that the city is in litigation with the Western Water & Light Co., and if a compromise can be effected nothing towards building works will be done. If no settlement can be arranged a new company will be organized and new water-works and a gas plant will be put in.

TOPEKA, KAN.—The council has been petitioned to call an election to vote on the question of purchasing the works of the Topeka Water Co.

OSCEOLA, MO.—The Osceola Water Supply Co. has been incorporated to supply Osceola with water; capital stock, $8,000. Incorporators, Robert Craig, T. J. Alexander, E. D. Miles and others.

ST. LOUIS, MO.—The following are the lowest bids received by the board of public improvements July 15 for furnishing several miles of cast-iron water pipe, etc.: Pipe—American Pipe & Foundry Co., $14.08 a ton, total $47,168. Laying, two contracts—George P. Prendergast, $11,400 and $8,520. Valves—Michigan Brass & Iron Works, $7,965. Special Castings—Magnetite Foundry Co., $6,200. Fire Plugs, 375—Pleuger & Enger, $7,450.

BLACK HAWK, COLO.—F. A. Randolph, Cy. Clk., writes us that D. Mitchell, Denver, Colo., has been awarded the contract for furnishing and constructing the works, at $26,804, excepting the pipe. The contract for furnishing the pipe has been let to E. E. Clark, Black Hawk, at $12,500, he being the only bidder on pipe. The bids received July 18 were as follows:

[1]D. Mitchell, Denver	$26,800
[2]Holmes & Allen, Denver	36,554
[1]James H. Tierney, Central City	41,800
[3]P. E. Anderson, Central City	12,500
[4]D. J. Tirsway, Denver	37,818
[4]Quigley & Co., Central City	53,750
[5]E. E. Clark, Black Hawk	12,500
[4]R. B. MacDonald Bldg. Co., Denver	39,322

[1]Complete without pipe. [2]Complete with pipe. [3]For reservoir only. [4]Complete. [5]Pipe only.

FLORENCE, COLO.—Hiram Phillips, 306 Oriel Bldg., St. Louis, Mo., is reported to have been engaged to report on a water supply for this city. Plans and estimates will be prepared, after which the question will be voted upon by the citizens. Mayor McGuire may be addressed.

BERKELEY, CAL.—The town trustees have appropriated $2,500 for hiring experts to look over the ground and report on the feasibility of a water supply. The committee consists of Dr. Thos. Addison, J. J. Le Conte, and E. F. Niehaus. Clk., M. L. Hanscom.

PASADENA, CAL.—The question of securing a new city charter, with a view to the municipal ownership of the water-works, is being considered. P. M. Green and H. G. Reynolds may be addressed.

VISALIA, CAL.—A new committee is reported to have been appointed to investigate the advisability of building works. Councilmen Roth and Stewart may be addressed.

FLAGSTAFF, ARIZ.—The council has let the contract for constructing the works to George W. Sturtevant, Chicago, at $85,000. The springs which will furnish the water supply are 17 miles from town, and have an average flow of 500,000 gallons daily. A force of men will be put to work immediately, the terms of the contract requiring that the system be completed within five months.

MOSCOW, RUSSIA.—Nicholas Simin, Ch. Engr. Moscow Water-Works, writes us that the councils have appropriated $32,800 to make experiments with different systems of mechanical filters. The future water supply of 40,000,000 gallons for this city will be secured from the Moscow River. The tests will continue for about a year.

SEWERAGE.

BELFAST, ME.—Bids are asked until Aug. 1 for constructing 3,500 ft. of pipe sewers. C. O. Poor, Chn. Com.

CLINTON, MASS.—Local papers state that bids will soon be asked by the Metropolitan Water Board, Boston, for constructing a sewage disposal plant for this city. Ch. Engr., F. P. Stearns, Boston.

SPRINGFIELD, MASS.—Bids are asked until Aug. 2 for constructing about 2,900 ft. of eliptical brick sewer, etc. C. M. Slocum, Cy. Engr.; W. L. Dickinson, Supt. Sts.

WINTHROP, MASS.—Bids are asked until July 30 for constructing a portion of the system in Winthrop Heights; check, $500; Engrs., Whitman & Howard, 85 Devonshire St., Boston; Chn. Com., H. A. Root.

NORFOLK, CONN.—Bids are asked until Aug. 10 for constructing about six miles of the system, as described in our advertising columns. Edmund Brown, Clk.

COHOES, N. Y.—The public improvement commission has engaged Prof. Palmer C. Ricketts, Rensselaer Polytechnic Institute, Troy, N. Y., to prepare plans for a system for this city.

LANCASTER, N. Y.—The board of sewer commissioners has approved the plans prepared by O. N. Gardner, of Jamestown, N. Y., for a system and for disposal works for the village. Fifteen plans were received July 7. The board of village trustees has decided to call a special election Aug. 1 to vote on the question of raising $1,200 by special tax.

PLATTSBURG, N. Y.—Bids are asked until Aug. 2 for constructing pipe sewers in a number of streets. H. E. Barnard, Acting Clk.; S. L. Wheeler, Chn. Com.

BAYONNE, N. J.—Bids are asked until Aug. 2 for building sewers in five streets. W. C. Hamilton, Cy. Clk.

JERSEY CITY, N. J.—Bids are asked until Aug. 1 for constructing 1,300 ft. of 42 to 18-in. sewers, etc. Geo. T. Bouton, Clk. St. and Water Bd.

MONTCLAIR, N. J.—Bids are asked until Aug. 8 for constructing an 8-in. pipe sewer in Portland Place. H. Tippett, Town Clk.

WOODSTOWN, N. J.—The question of building a system is being considered, according to reports.

KANE, PA.—Bids are asked until Aug. 1 for sewers in six streets. P. B. Anderson, Secy.

LATROBE, PA.—Bids are asked until Aug. 8 for constructing a 12-in. pipe sewer in Thompson St. Engr., L. W. Fogg; Secy., H. M. Fink; Burgess, C. H. Eiseman.

READING, PA.—Bids are asked until July 28 for furnishing and laying about 38,000 ft. of pipe sewers. S. S. Hoff, Cy. Engr.

READING, PA.—Bids are asked until July 28 for constructing a by-pass or overflow at the sewage pumping station; bond, $2,500; S. S. Hoff, Cy. Engr.

WILLIAMSPORT, PA.—John Welteroth has been awarded the contract for building the West End main sewer. Mayor Mansel may be addressed.

WILMINGTON, DEL.—Bids are asked until Aug. 5 for constructing storm water drains and grading and macadamizing in the Wilmington and Brandywine Cemetery. M. M. Cleaver, Secy., 602 Market St.

CHESTERTOWN, MD.—Wm. T. Sutton, Chestertown, has been awarded the contract for constructing a sewer in Washington and Maple Aves., at $1,625.

WASHINGTON, D. C.—The district commissioners have ordered the construction of the extension of the Burleith main sewer along 37th St. to Y, and in Y St., from 37th to 38th St. Estimated cost, $7,656.

ELKINS, W. VA.—W. W. Mills, Recdr., writes us that the contract for building 2,100 ft. of 20-in. pipe sewer has been let to K. G. Lyons. Engr., I. W. Galbreath, Elkins.

COLUMBIA, S. C.—C. C. Wilson, Cy. Engr., has submitted plans and estimates for a system and water-works, to cost about $450,000; the system itself to cost about $125,000. We are informed that the matter is not in shape for any definite information.

ASHTABULA, O.—Bids are asked until Aug. 13 for constructing 1,284 lin. ft. of 8-in. pipe sewers, etc., as stated in our advertising columns. H. E. Mann, Cy. Engr.; Frank W. Wagner, Cy. Clk.

LIMA, O.—Bids are asked until July 28 for constructing sewers in several streets. C. E. Lynch, Cy. Clk.

OBERLIN, O.—Bids are asked until Aug. 15 for the purchase of $1,900 of sewer bonds and until Aug. 16 for constructing 2,500 ft. of 6-in. pipe sewer. W. B. Gerrish, Cy. Engr.

PAW PAW, MICH.—This place voted July 12 against issuing $5,000 in bonds for a system, although it voted to issue $18,000 in bonds for water-works.

WAVERLY, IA.—Bids are asked until Aug. 2 for constructing 8-in. pipe sewers in several streets. D. A. Long, Cy. Clk.

TOPEKA, KAN.—The question of building sewers in North Topeka is being considered; population, 4,000.

EMERYVILLE, CAL.—We are informed that Thos. N. Badger, Town Engr., is preparing plans and specifications for a system. There will probably be about 20,000 ft. of 14 to 6-in. pipe; average cut, 7.7 ft. It will be several weeks before bids for the work are asked. W. H. Christie, Pres. Bd. Trustees.

OAKLAND, CAL.—The Lake Merritt Sanitary Improvement Club has been organized to advocate the building of more sewers in the city around Merritt Lake, and also the cleansing of that lake. Edwin Goodall, A. Schilling and H. F. Gordon may be addressed.

POMONA, CAL.—Stoddard Jess, W. H. Sanders and J. H. Graber have been appointed a committee to gather data for an outfall sewer and a sewerage system. City Clerk Lee is to communicate with Redlands, Riverside, Santa Ana, Santa Monica, and Pasadena, with regard to a joint sewer.

SANTA ANA, CAL.—E. H. Rollins & Son, Boston, Mass., are reported to have been awarded the bonds amounting to $65,000 for the proposed system. It is stated that the trustees will soon ask for bids for building the system.

JUNEAU, ALASKA.—The "Miner" is again urging the construction of a sewerage system.

GARBAGE DISPOSAL—STREET CLEANING

UTICA, N. Y.—The council has awarded the contract to Henry Stappenbeck, at $6,500 a year, for collecting and destroying the garbage for a term of 10 years.

WHITE PLAINS, N. Y.—The following bids were received July 11 by the board of trustees for collecting and disposing of the garbage: John Jackman, dumping ground his own, $2,850; Jay F. Crawford, dumping ground, Shampnois Swamp (accepted), $1,576; Antonio Martinello, no dumping ground stated, $1,300; Thos. O'Rourke, dumping ground not stated, $1,105; P. J. Mannix, no dumping ground stated, $936.

ATLANTIC CITY, N. J.—Mayor Jos. Thompson, Councilman Leeds, Prof. Wm. P. Landenslager and H. S. Scoll have visited Reading to inspect the garbage disposal plant, with a view to putting in one soon.

PERTH AMBOY, N. J.—Press reports state as follows: The board of health on July 25 considered the question of disposing of the garbage of the city. The first year under the contract system is about to expire, and a new contract will be made at the next session of the board of aldermen. Although there is an ordinance directing that the garbage and ashes be separated, it is seldom done, and the dumping of the mixture causes a nuisance, which the board has been endeavoring all the year to abate. At a recent meeting of the board a resolution was adopted prohibiting the dumping of garbage or ashes within the city limits. It is contended that the board cannot legally do this.

MILWAUKEE, WIS.—Comptroller John R. Wolf has countersigned a resolution drafted by Chairman Graebner of the committee on health, with the approval of the committee, instructing the board of public works to advertise for bids for a municipal garbage plant, to be erected on Jones Island; the plant capable of disposing of 100 tons of garbage a day. The ordinance to issue bonds for the plant will doubtless be repealed, the amount needed for the plant to be taken from the other funds. Estimated cost, $60,000.

ST. LOUIS, MO.—The following bids were received by the board of health July 14 for collecting and disposing of the garbage for 10 years:

Edward Butler, 13 South 10th St.—$245,031, $250,160, $264,489, $275,112, $286,302, $296,682, $302,710 $321,411, $340,190, $359,875 a year; total for 10 years, $2,941,982.

Hill-O'Meara Construction Co.—$261,000, $266,000, $266,000, $266,000, $271,000, $271,000, $271,000, $271,000, $277,000, $277,000; total, $2,697,000.

Rich & Sale, Rowe Bldg.—$196,000 for each of the 10 years; total, $1,960,000.

Wade & Miller.—$200,000, $175,000, $175,000, $185,000, $190,000, $195,000, $200,000, $200,000, $205,000, $210,000; total, $1,935,000.

J. W. Thompson & Co., Wainwright Bldg.—$120,000, $123,000, $126,000, $129,000, $132,000, $135,000, $138,000, $141,000, $144,000, $147,000; total, $1,335,000.

Excelsior Hauling & Transfer Co.—$80,000, $127,200, $127,200, $127,200, $127,200, $127,200, $127,200, $127,200, $127,200, $127,400; total, $1,225,000. Awarded contract.

SANTA BARBARA, CAL.—Bids are being asked by the council for the construction of a pumping plant to supply salt water for sprinkling the first district, the cost not to exceed $3,000, according to reports.

STREETS AND ROADS.

LEWISTON, ME.—Bids are asked by the council until July 28 for furnishing and laying about 3,000 sq. yds. of granite pavement.

LACONIA, N. H.—S. C. Frye, Cy. Clk., informs us that the following bids were received July 18 for constructing the Weirs Road, as advertised in Engineering News:

	For 16-ft. roadway.	For 26-ft. roadway.
Frederic R. Page & Co., Boston, Mass.	$5,117	*$6,584
Edwin D. Bell, Roxbury, Mass.	5,520	8,013
Joseph D. Gennaro, Boston, Mass.	9,078	12,283
A. R. Smith, Plymouth, N. H.	8,355	13,200
John Walker, Newmarket, N. H.	10,049	14,437
Fred. T. Ley & Co., Springfield, Mass.	9,134	13,461
Chas. A. Bailey, Suncook, N. H.	12,887	18,234
Stone & Thurston, 220 Broadway, N. Y.	20,375	29,257

---

*Awarded contract.

SALEM, MASS.—Bids are asked until Aug. 8 for widening and grading a portion of Lafayette St., in Salem, and Pleasant St., in Marblehead. Putnam & Ricker, Engrs., 251 Essex St., Salem.

SOUTH NORWALK, CONN.—The council has voted to pave South Main St. with brick, from Monroe St. to Woodward Ave.; estimated cost, $10,935. Joseph R. Taylor, Clk.

EAST AURORA, N. Y.—G. W. Partridge submitted the lowest bid July 11 for paving in Main St., at $8,000 for macadam, and at $11,000 for brick. C. H. Addington, Clk.

JAMESTOWN, N. Y.—Bids are asked until July 30 for brick paving. W. O. Benedict, Bd. Pub. Wks.

OLEAN, N. Y.—Bids are asked until Aug. 12 for constructing about 2,000 sq. yds. of brick pavement on concrete foundation, as stated in our advertising columns. E. E. Allen, Supt. of Streets.

ROCHESTER, N. Y.—Bids are asked until Aug. 5 for paving East Main St. with brick, estimated cost $74,700; Clarissa St., asphalt, $12,000; Clarissa St., retaining walls; Pierpont Ave., asphalt, $26,000; Austin St., cement walks, $2,025; Minerva Place, brick, $1,800. Edwin A. Fisher, Cy. Engr.; Chas. M. Beattie, Clk.

SCHENECTADY, N. Y.—Bids are asked by the council until Aug. 9 for brick paving in Dock St.

WHITE PLAINS, N. Y.—Bids are asked until Aug. 1 for macadamizing, etc., in Lexington Ave., between Martine and Fisher Aves., and grading East Barker Ave. and Warren St.; also until Aug. 2 for furnishing and constructing 4-ft. sidewalks, etc., on Fisher Ave. S. C. Miller, Pres.; E. G. Sutherland, Clk.

ATLANTIC CITY, N. J.—Portions of South Carolina, Tennessee and Arkansas Aves. will be paved with brick. President Southwick may be addressed.

CARLSTADT, N. J.—Bids are asked until Aug. 4 for the purchase of $30,000 of grading and macadamizing bonds. Frank Erdle, Borough Clk.

JERSEY CITY, N. J.—Bids are asked until Aug. 1 for about 689 sq. yds. of Belgian paving, 2,850 sq. yds. of asphalt paving, 3,372 lin. ft. of curbing, etc., on portions of Duncan and Highland Aves. Geo. T. Bouton, Clk. Bd. St. Comrs.

PATERSON, N. J.—Bids are asked until Aug. 1 for the purchase of $30,000 of 5% road bonds. E. G. Edwards, Chn. Bd. Freeholders.

PATERSON, N. J.—The aldermen have voted to pave portions of Colt, Hamilton, Market and other streets with asphalt block and Broadway with brick. About $97,000 has been appropriated.

RIVERTON, N. J.—Bids are asked until July 28 for about 2,100 lin. ft. of asphalt tile sidewalk and foundation 5 ft. wide. Henry S. Haines, Engr., Temple Bldg., Camden; Chas. S. Walnut, Borough Clk.

WOODBURY, N. J.—The board of freeholders has granted a petition for the construction of a stone road from Woodbury to Knight Run, a distance of 5¼ miles; estimated cost, $7,560. Messrs. [illegible]arpley, Knight, Pierson, Hendrickson and Starr have been appointed a committee to carry on this and other road improvements. Wm. M. Carter, Engr.

McKEES ROCKS, PA.—It has been voted to issue $40,000 in bonds for street improvements.

READING, PA.—The board of public works has rejected the bids received July 18 for 30,000 lin. ft. of granite curbing and 52,000 sq. yds. of sheet asphalt paving, for which $100,000 has been appropriated. The bids were too high. S. S. Hoff, Cy. Engr.

RIDGWAY, PA.—Bids are asked until Aug. 5 for paving about 2,000 lin. ft. of roadway, constructing drains, etc., as stated in our advertising columns. A. B. Little, Engr.; W. W. Barbour, Chn. St. Com.

SHARPSBURG, PA.—An ordinance will be presented to the council for issuing $60,000 in bonds for the improvement of highways. Geo. H. Ayres, Chn.; Wm. C. Tibby, Geo. D. McMarran, Geo. L. Keil, Councilmen.

WILKINSBURG, PA.—Bids are asked until Aug. 3 for grading, curbing and brick paving in portions of Clark St. and three other streets. Frease & Sperling, Engrs.

BALTIMORE, MD.—The board of public works has awarded a contract to the Southern Asphalt Paving Co., Baltimore, at $29,951, for paving Fulton Ave., and at $35,814, for paving Mount Roval Ave.

ROCKVILLE, MD.—Bids are asked until Aug. 10 for grading and macadamizing about nine miles of county roads, as stated in our advertising columns. W. W. Welsh, Clk. County Comrs.

ALEXANDRIA, VA.—Bids are asked until Aug. 11 for furnishing and constructing 500 lin. ft. of curb and 1,060 sq. yds. of brick pavement, as stated in our advertising columns. E. B. Dunn, Cy. Engr.

CHARLESTON, S. C.—Bids are asked until Aug. 3 for paving the county roadway with granite blocks. Wm. P. Cantwell, County Supv.

ROME, GA.—Broad St. will be paved with brick between the Etowah River and Second Ave. Address Chairman Denny or City Engineer Smith.

NEW ORLEANS, LA.—Bids are asked until Aug. 8 for paving, etc., in Camp St., Claiborne Ave. and Canal St., as follows: 65,250 sq. yds. of sheet or rock asphalt on 4 to 6-in. concrete foundation; 135,000 brick, 289,200 lbs. of cast iron, 6,550 lin. ft. of curb, 9,500 lin. ft. of curb to reset, 38,500 ft. B. M. of cypress lumber, 650 sq. yds. of gutter buttons, etc. A. C. Bell, Cy. Engr.; P. A. Rabouin, Comptroller.

CHILLICOTHE, O.—Bids are asked until Aug. 13 for paving certain streets with brick, as stated in our advertising columns. H. M. Redd, Cy. Engr.; W. J. Eyth, Cy. Clk.

CLEVELAND, O.—Bids are asked until Aug. 19 for grading, draining and asphalt paving on the Superior St. viaduct. Geo. R. Warden, Dir.

DEFIANCE, O.—Bids are asked until Aug. 18 for excavating and grading in North Clinton St. and Ralston Ave. J. J. Malley, Cy. Clk.

LANCASTER, O.—Bids are asked until Aug. 13 for brick paving on Main St., from Broad to Maple St. H. T. Mechling, Cy. Clk.

LORAIN, O.—A committee consisting of D. C. Fisher and others have been appointed to consider the question of paving in Second St.

MANSFIELD, O.—Bids are asked by the clerk until Aug. 20 for the purchase of $10,000 of 6% street bonds.

OBERLIN, O.—Bids are asked until Aug. 15 for the purchase of $4,000 of paving bonds and until Aug. 16 for constructing 2,000 sq. yds. of brick pavement. W. B. Gerrish, Cy. Engr.

ST. BERNARD, O.—Bids are asked until Aug. 17 for constructing sidewalks on the bridge over the canal on the Carthage pike road. E. L. Lewis, County Audr., Cincinnati.

SWANTON, O.—Thos. McKinney was awarded a contract July 11 at $6,524 for about 4,500 sq. yds. of brick paving. F. H. Aldrich, Clk.

LAPORTE, IND.—Bids are asked until July 29 for about 9,000 sq. yds. of brick paving, according to reports. Geo. Koenig, Clk.

VERNON, IND.—Walter S. Downs and Peter Van Cleve, Viewers, and W. B. Prather, Engr., have submitted a report to the county commissioners on 17 miles of proposed macadamizing, at an estimated cost of $40,342.

DETROIT, MICH.—Bids are asked until July 30 for furnishing the material and for constructing about 22,000 sq. yds. of cedar block pavement on concrete, etc., in portions of Seward Ave., Orleans St. and seven other streets. D. W. H. Moreland, Pres. Bd. Pub. Wks.

CHICAGO, ILL.—Bids are asked until Aug. 1 for grading, curbing and cedar block paving in Franklin Ave., at River Forest. Robt. E. Williams, Engr., 84 State St., Chicago; T. M. Jackson, Pres.

PEORIA, ILL.—Bids are asked until July 28 for 5,255 sq. yds. of asphalt paving, 3,208 cu. yds. of excavation, 3,346 lin. ft. of curb and gutter. M. W. Manning, Chn. Bd. Local Improvements; A. D. Thompson, Cy. Engr.

ROCKFORD, ILL.—Bids are asked until Aug. 1 for furnishing and constructing about 7,580 sq. yds. of asphalt and 2,885 sq. yds. of brick pavement in East State St. E. W. Brown, Pres. Bd. Local Improvements; Edwin Main, Cy. Engr.

JANESVILLE, WIS.—Bids are asked until Aug. 1 for grading, curbing and macadamizing South Main St., between Racine St. and Carrington St. A. E. Badger, Cy. Clk.

SHEBOYGAN, WIS.—Bids will soon be asked by the board of public works for the purchase of a road roller, to weigh about 28,000 lbs.

MINNEAPOLIS, MINN.—Bids are asked until July 29 for furnishing artificial combined curb and gutter. L. A. Lydiard, Cy. Clk.

BURLINGTON, IA.—Bids are asked until Aug. 1 for brick paving, etc., in Arch St., from Third to Fourth St. Emmet Steece, Cy. Engr.

COUNCIL BLUFFS, IA.—A resolution has been passed for the paving of portions of Ave. F, Pierce St. and five other streets, with brick.

SEDALIA, MO.—An ordinance will be presented to the council by A. P. Morey and others, for brick paving on Ohio St.

ST. LOUIS, MO.—Mayor Ziegenhein has recommended an ordinance appropriating $100,000 for paving, to be presented in the general appropriation bill.

SPOKANE, WASH.—Bids are asked until Aug. 10 for grading, curbing and guttering in Chestnut St. and Mission Ave. H. B. Fowle, Secy. Bd. Pub. Wks.

OGDEN, UTAH.—The county commissioners will spend about $2,500 for road improvements this year.

MANUFACTURING PLANTS.

BUFFALO, N. Y.—The People's Brewing Co., recently incorporated, is reported to have purchased a building on Broadway, near the Belt line. This building will be remodeled and machinery for a brewery will be put in. M. Hilburger, Buffalo, is preparing the plans and specifications. The plans for the machinery will be prepared by Emil Krampitz, of Buffalo. The brewery will have a capacity of 30,000 barrels of beer a year. Capital stock, $120,000. Jos. E. Barnard, Geo. Baltz and C. R. Rossler, of the Rossler Carriage & Buggy Co., are interested.

DUNKIRK, N. Y.—The Buffalo Bridge & Iron Works has been awarded the contract for erecting a 220 × 80 × 36-ft. addition to the plant of the Brooks Locomotive Works. It will be of steel and have two heavy overhead cranes.

TROY, N. Y.—The Troy Laundry Machinery Co., Thomas S. Wiles, Pres., is negotiating for the purchase of a portion of the plant of the Gilbert Car Works property on Green Island, and it is probable that the transfer will be made in a few days. The plant of the company on Fulton St. has become inadequate, and it was found necessary to enlarge. The present establishment will be continued in conjunction with the new one.——Additions and alterations are to be made to the Troy Paint Works, Wm. Connors, Pres.; estimated cost, $22,000. Archs., M. F. Cummings & Son, Troy.

CONNELLSVILLE, PA.—Press reports state that the plant of the Slaymaker-Barry Co., which was destroyed by fire about five weeks ago, is to be rebuilt. Plans have been prepared and the contract let for the padlock factory. The buildings will be of iron and steel, and will cost $20,000. The main building will be 70 × 400 ft. Besides this there will be a boiler room 35 × 42 ft., an engine room 36 × 40 ft., and a stock house 20 × 40 ft. The contract for the entire building, machinery included, has been let to Edward Erickson, contracting engineer, Pittsburg, Pa. Mr. Erickson has also secured the contract for putting in two new mills at the plant of the Humbert Tin Plate Co., Connellsville. An addition to the building will be made, the contract for this part of the work having been secured by W. B. Scaife & Sons, Pittsburg, while all the other work will be furnished by Mr. Erickson.

ROCKINGHAM, N. C.—Press reports state that the Pee Dee Mfg. Co. will begin at once the building of Mill No. 2. The structure will be two stories high, 317 × 100 ft., and its equipment of machinery will include 6,000 spindles, 300 looms, dyehouse equipment and the necessary engine and boilers to furnish the power. This machinery has not yet been purchased.

SALISBURY, N. C.—Geo. R. Collins has purchased the plant of the Artificial Ice Co., and, it is stated, will put in new machinery at once.

ROCK HILL, S. C.—Wm. O. Webber, Consulting Engr., 53 State St., Boston, Mass., writes us that the contracts have not yet been let by the Rock Hill Cotton Factory Co. for furnishing the machinery and for constructing its plant. There will be a 1½-story building, 100 × 230 ft., a 2-story building, 30 × 80 ft., etc., supplied with steam heating, electric lights, spindles, etc.; estimated cost, $20,000. The equipment will include a 600-HP. engine, etc.; estimated cost of equipment, $120,000.

JACKSONVILLE FLA.—It is reported that the Duval & Clay Sugar Co. will increase its capital stock, which is now $300,000, for constructing and equipping a new mill. Treas., J. F. Eldridge.

MISCELLANEOUS CONTRACTS.

FIRE HOSE.—Troy, N. Y.—Bids are asked until Aug. 1 for furnishing fire hose. C. W. Peoble, Clk. Fire Bd.

DITCH.—Lafayette, Ind.—Bids are asked until July 29 for constructing a drainage ditch. M. W. Miller, Chn. Com.

BONDS.—Poplarville, Miss.—Bids are asked until Aug. 15 for the purchase of $2,500 of bonds. R. H. Reeves, Town Clk.

LADDER TRUCK.—Cincinnati, O.—Bids are asked until Aug. 2 for furnishing one ladder truck. C. F. Lakeman, Secy. Bd. Fire Trustees, 66th St.

BONDS.—Newark, N. J.—Bids are asked until Aug. 10 for the purchase of $500,000 of 4% park improvement bonds. D. H. Johnson, Chn. Finance Com.

DITCH.—Kenton, O.—Bids are asked until Aug. 6 for constructing the Scioto River ditch improvement. W. E. Myers, Engr.; James Bastable, County Audr.

DREDGING.—Norfolk, Va.—Bids are asked until Aug. 3 for dredging the Elizabeth River from Hampton Roads to Norfolk. Capt. Thos. L. Casey, U. S. Engrs., Norfolk.

LEVEE WORK.—Desha County, Ark.—Bids are asked until Aug. 5 for levee work. Address Board of State Engineers, Cotton Exchange Bldg., New Orleans, La.

DRAINAGE DITCH.—Arthur, Ill.—Bids are asked until Aug. 6 for constructing a drainage ditch, etc., about 23,936 cu. yds. of excavation. W. M. Fleming, Town Clk.

DREDGING.—Montgomery, Ala.—Bids are asked until Aug. 20 for dredging at entrance to Pensacola Bay, Fla., as stated in our advertising columns. Maj. F. A. Mahan, U. S. Engrs.

RIVER WORK.—Buffalo, N. Y.—Bids will soon be asked by the harbor commissioners for work on section A in the Buffalo River, including a channel 230 ft. wide and 20 ft. deep.

HOSE WAGON.—Leavenworth, Kan.—Bids are asked until Aug. 3 for furnishing a combination chemical and hose wagon, to cost about $1,000. Geo. W. Kaufmann, Chn. Com.

HIRE OF DREDGING PLANT.—Mobile, Ala.—Bids are asked until Aug. 24 for the hire of dredging plant for Mobile River and Bay, as stated in our advertising columns. Maj. Wm. T. Rossell, U. S. Engrs.

LEVEE WORK.—Columbus, O.—Reports state that Julian Griggs, Cy. Engr., has submitted an estimate of $752,618 for the necessary strengthening of the west side levee.

DRY DOCKS.—New Orleans, La.—Reports state that the New Orleans & Western Ry. Co. will construct four new docks, 150, 300, 350 and 1,500 ft. long, to cost about $200,000, at Port Chalmette.

TELEPHONE SYSTEM.—Clarence, Mo.—Bids were received July 23 for the purchase of a franchise to construct and operate a telephone system. H. J. Simmons, Mayor; A. B. Irwin, Cy. Clk.

FIRE ENGINES AND BOILERS.—Chicago, Ill.—Bids are asked until Aug. 3 for furnishing one first-size and two second-size Metropolitan steam fire engines, and two extra boilers, 31 × 64 ins. D. J. Sweenie, Fire Marshal.

SUBMARINE PIPELAYING.—Philadelphia, Pa.—Lewis F. Shoemaker & Co., 417 Fidelity Building, advised us last week that they wished to engage a man for two or three months to lay pipe in about 7 ft. of water.

SUPPLIES.—Memphis, Tenn.—Bids are asked until Aug. 18 for furnishing brush, poles, riprap stone, wire, rope and other supplies, as stated in our advertising columns. Capt. Mason M. Patrick, U. S. Engr., 36 Equitable Bldg.

TILE AND EXCAVATING.—Champaign, Ill.—Bids are asked until Aug. 6 for excavating about 13,566 cu. yds. of earth and for furnishing, hauling and laying about 6,300 lin. ft. of 8 to 18-in. tile. Chas. Witt, Chn. Drainage Comn.

DRAINAGE DITCH.—Ottawa, Ill.—Bids are asked until Aug. 15 for constructing about 8 miles of drainage ditch in Wallace and Waltham. About 100,000 cu. yds. of excavation will be required. Chas. F. Wilson, Engr.; Samuel Bonnefoy, Clk., Ottawa.

FIRE ALARM SYSTEM, ETC.—Oakland, Cal.—A petition has been presented to the council by Edward J. Wolfe, David Bibber and Frederick Kahn, for permission to construct and maintain a burglar, police, fire alarm and a district telegraph messenger system. Bids will be asked for the purchase of a franchise.

HYDRAULIC DREDGE.—St. Louis, Mo.—The following bids were received July 22 for furnishing a hydraulic dredge, as advertised in Engineering News. Capt. H. E. Waterman, U. S. Engrs., Secy., Mississippi River Comn.:

	Dredge.	Refrigerating plant.
Springfield Boiler & Mfg. Co., Springfield, Ill.	$94,970	$2,981
Edw. Flad, St. Louis, Mo.	98,981	2,300
The Bucyrus Co., South Milwaukee, Wis.	129,760	2,448

INDUSTRIAL NOTES.

THE FISHER GOVERNOR CO., Marshalltown, Ia., writes us that it has recently sold 20 governors to one firm and 11 to another firm in Cleveland, O.

THE BIRMINGHAM PIPE WORKS, Birmingham, Ala., was sold July 16, at public auction by R. C. White, assignee, according to report, to the Ahrens & Ott Mfg. Co., Louisville, Ky., for $1,000 cash, and $5,000 in liens, which were assumed by the latter company.

THE PITTSBURG LOCOMOTIVE & CAR WORKS, Pittsburg, has an order from the Wheeling Bridge & Terminal Co., Wheeling, W. Va., for six 100,000-lb. switching locomotives, with Westinghouse air-brakes, to cost about $75,000 each, according to report.

THE STILWELL-BIERCE & SMITH-VAILE CO., Dayton, O., is said to have received an order, through its representative, Mr. A. H. Dalzell, Ogdensburg, N. Y., for two 48-in. Victor water wheels and other apparatus for the power pumps of the Ogdensburg city water-works.

THE FRONTIER IRON WORKS, Detroit, Mich., is adding new brass furnaces to its plant and increasing the size of its brass foundry, in order to take care of the increase in its valve business. The company states that the demand for its Frontier hot water radiator valves is beyond precedent.

THE WEBER RAILWAY JOINT MFG. CO., Cotton Exchange Bldg., New York, has elected the following officers: Emil Greeff, Pres.; Edward Y. Weber, Vice-Pres. and Treas.; George A. Weber, Secy., and Percy Holbrook, Gen. Mgr.

THE BERLIN IRON BRIDGE CO., East Berlin, Conn., has a contract from the New Haven Gas Light Co., New Haven, Conn., for its new fireproof coal shed, 60 × 500 ft., with a steel frame arranged so that the coal cars are brought into the building on a track supported by the roof trusses, thus providing the maximum storage at the least expenditure of power and room.

THE SEMI-STEEL CO., King & Andrews Co., proprietors, Chicago, reports that it has just completed its large new foundry at Chicago Heights, Ill. The following roads have tracks into the yards: Chicago & Eastern Illinois R. R., Michigan Central Ry., and Elgin, Joliet & Eastern Ry., giving the factory excellent shipping facilities to all points. The factory was recently described in our columns.

THE KEYSTONE BRIDGE CO., Pittsburg, is reported to have the contract to build the Buffalo, Rochester & Pittsburg R. R. bridge, 1,600 ft. long, 125 ft. high, and 25 ft. wide, over the Allegheny River, at Moss Grove, near Pittsburg, at a cost of $150,000. The Jutte & Foley Co., Pittsburg, has the contract for the substructure. E. K. Morse, Pittsburg, is the engineer in charge of the work.

THE PITTSBURG BRIDGE CO., Pittsburg, Pa., has received through Collins & Norton, New England agents, a contract from the Dwight Mfg. Co., Chicopee, Mass., to build a steel roof over its boiler house which was recently destroyed by fire. This will do away with all wood work in the building. The town of Brookfield, Mass., has also placed a contract with the company for a new bridge on the state highway in the town of East Brookfield, Mass.

THE AMERICAN IMPULSE WHEEL CO., 120 Liberty St., New York, states that it is making steady headway with its improved water wheel in this and foreign countries. The company has wheels installed in Japan, France, Sweden and Scotland, which are reported as giving favorable results, and among contemplated large power and transmission plants in Utah, Canada, Montana and Minnesota the wheels are also being given serious consideration. Mr. Thorburn Reid is Consulting Engineer of the company.

THE STOREY MOTOR & TOOL CO. has moved its main office and factory from Philadelphia to 464 South Broad St., Trenton, N. J., in the plant with the Trenton Iron Co. The change has been made necessary by the increased demand for its electrical machinery, particularly the multipolar, enclosed, dust and moisture-proof motors, the first of this style, it is claimed, to be placed on the market. The company, with its increased facilities, will also push the sale of its open-type machines for all classes of standard work, together with several lines of specialties which up to the present it has been unable to put upon the market.

PERSONAL.

Mr. Val. Morrison has been appointed Manager of the water-works at Ennis, Tex.

Mr. James W. G. Walker has been appointed a Civil Engineer in the United States Navy, with rank of Lieutenant, junior grade.

Mr. Jacob L. Kuehn, for over 40 years Superintendent of the York Water Co. and of the York Gas Co., York, Pa., has resigned the former position.

Dr. David Gill, the British astronomer at the Cape of Good Hope, South Africa, has been elected a Foreign Member of the National Academy of Sciences, Washington, D. C.

Mr. James Donnelly, for many years Division Superintendent of the Easton & Amboy and the Lehigh Divisions of the Lehigh Valley R. R., with headquarters at Easton, Pa., has resigned; to take effect Sept. 1.

Mr. Alexander Rice McKim, M. Am. Soc. C. E., consulting engineer, of New York city, has accepted the position of Resident Engineer of the Pittsburg Testing Laboratory, Ltd., Pittsburg, Pa., with headquarters at 106 East 23d St.

Mr. George Schley, consulting civil and mining engineer, leaves for British Honduras Aug. 8, to be gone about eight weeks. During his absence he will be represented by Mr. George R. Olney, 27 Thames St., New York city, or 16 Willow Ave., Stamford, Conn.

Rear-Admiral John G. Walker, retired, U. S. Navy, has been appointed a member of the commission to examine the plans for a bridge across the Niagara River, at Grand Island. The plans must be approved by both the United States and the Dominion of Canada.

Mr. Theodore Belzner, Jun. Am. Soc. C. E., 111 Broadway, New York, has resigned his position as Assistant Engineer to the expert in charge of buildings of that city, which he has held for the past two years. He has also been an assistant expert on the valuation of buildings for three years.

Mr. A. J. Churchyard, formerly connected with the Excelsior Co. as Electrical Engineer, has been appointed to a position in the engineering department of the Fort Wayne Electric Corporation, Fort Wayne, Ind. He is best known for his work with single-phase alternating motors and rotary transformers.

Mr. Robert L. Gifford, civil engineer, of Chicago, Ill., has associated himself with Mr. Robert G. Dwen, architect, of the same city, in the joint practice of architecture and engineering, with offices at 187 Dearborn St. Mr. Dwen was formerly associated with Mr. Murray A. White under the firm name of Dwen & White, architects.

Mr. Charles E. Billin, Western Representative of Bement, Miles & Co., Philadelphia, has resigned and will in the future devote all his attention to the business of Chas. E. Billin & Co., Chicago, Ill., which firm is acting as engineers and purchasing agents for a number of mining properties in the western states and in Mexico.

Herr Max Buhle, Assistant Professor in the Royal Technical High School of Berlin, and a Member of the German Society of Engineers, is visiting the United States to study American practice in hoisting and conveying machinery, coal, ore and grain handling machinery, street railways and other fields of engineering work. Prof. Buhle will visit Boston, Schenectady, Niagara Falls, Buffalo, Cleveland, Chicago, Milwaukee, Minneapolis and St. Paul, Duluth and Superior, St. Louis, Washington, Philadelphia, and may possibly extend his trip to San Francisco. Prof. Buhle will be glad to receive the catalogues of American manufacturers of engineering materials, which may be sent to him in care of Thos. Prosser & Sons, 15 Gold St., New York city.

OBITUARY.

Mr. J. M. Byers, contractor, of Oskaloosa, Ia., died there July 24, aged 85.

Mr. William H. Bates, contractor, of St. Charles, Mo., died July 24, aged 75.

Mr. W. H. Holly, Superintendent of the Paducah Water Co., Paducah, Ky., died July 23, aged 48.

Mr. William P. Merrill, who built the first water-works of Milwaukee, Wis., died at Battle Creek, Mich., July 25, aged 82.

Mr. Claude W. Matson, civil engineer, of Brookville, Pa., was killed July 28 while attempting to board a train at Pittsburg. He was 27 years of age.

Mr. George Josselyn, mechanical engineer, of Cedar Rapids, Ia., died July 22, aged 77. He was born in Kingston, Jamaica, W. I. I., and was educated in Neuwiede, Germany. In 1839 he came to the United States and settled at Dayton, O. He was the Superintendent of Construction for the Josselyn & Taylor Co., Cedar Rapids, at the time of his death.

Dr. E. Lewis Sturtevant, formerly President of the Society for the Promotion of Agricultural Science, died at his home in Framingham, Mass., July 30. He was born in Boston, Jan. 23, 1842, and graduated from Bowdoin College, Brunswick, Me., in 1863. In 1866 he graduated from the medical department of Howard University and devoted himself to agricultural science. He was a Fellow of the American Association for the Advancement of Science.

Mr. Joseph Banigan, rubber manufacturer and formerly President of the United States Rubber Co., of Providence, R. I., died July 29. He was born in Carickadoncey, Ireland, June 5, 1839, and came to this country when eight years of age. He learned the jeweler's trade and then made a study of rubber, later engaging in the manufacture of rubber bottle stoppers. He soon afterwards discovered, it is said, a process for vulcanizing rubber and established the Goodyear India Rubber Bottle-Stopper Co. in Boston, Mass., and was its Manager until 1866. At that time he organized the Woonsocket Rubber Co., Woonsocket, R. I., and was its Superintendent and Manager. Three years ago he was made the President of the United States Rubber Co. at a salary of $50,000 a year. He was also President of a number of other companies and was interested in various manufacturing enterprises.

Mr. Edward Appleton, civil engineer, of Reading, Mass., died there July 31. He was born in Boston, Jan. 25, 1816, and graduated from Harvard University in 1835. After two years spent in tutoring he began the study of civil engineering in the office of James Hayward, being employed on the construction of the Boston & Maine R. R. in Haverhill, Dover and Exeter. In 1842 and 1843 he was Principal of the Beverly Academy and in 1844 returned to the Boston & Maine, in charge of the construction of the line from Wilmington to Greenwood. In 1846 he located in Reading, and spent the remainder of his life on railway work in the New England States, and also in New York, Pennsylvania, Ohio and Wisconsin. For several years he was Chief Engineer of the Boston, Hartford & Erie R. R., now the New England R. R. He was a railroad commissioner of Massachusetts in 1869 and 1870, and was also President of the Troy & Greenfield R. R. for several years. In 1890 he retired from professional work.

ENGINEERING SOCIETIES.

COMING TECHNICAL MEETINGS.

THE LOUISIANA ENGINEERING SOCIETY.
Aug. 8. "Deep Bridge Foundations at the Atchafalya River, T. & P. Crossing," C. H. Chamberlin. Secy., J. F. Coleman, 712 Union St., New Orleans, La.
CIVIL ENGINEERS' CLUB OF CLEVELAND.
Aug. 9. Secy., Wm. H. Searles, Case Library Bldg., Cleveland, O.
MONTANA SOCIETY OF ENGINEERS.
Aug. 13. Secy., A. S. Hovey, National Bank Bldg., Helena, Mont.
ENGINEERS' CLUB OF MINNEAPOLIS.
Aug. 15. Secy., H. E. Smith, 1620 S. E. 4th St., Minneapolis, Minn.
ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.
Aug. 16. Secy., R. A. Fessenden, 410 Penn Ave., Pittsburg, Pa.
WESTERN FOUNDRYMEN'S ASSOCIATION.
Aug. 17. Secy., B. M. Gardner, 1522 Monadnock Block, Chicago, Ill.
NEW ENGLAND ROAD MASTERS' ASSOCIATION.
Aug. 17. Annual meeting, Boston, Mass. F. C. Stowell, B. & M. R. R., Ware, Mass.
SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.
Aug. 18 to 20. Annual meeting at Massachusetts Institute of Technology, Boston, Mass. Secy., Albert Kingsbury, Durham, N. H.
AMERICAN MATHEMATICAL SOCIETY.
Aug. 19-20. Annual meeting, Boston, Mass. Secy., F. N. Cole, Columbus University, New York city.
AMERICAN CHEMICAL SOCIETY.
Aug. 22-23. Annual meeting, Boston, Mass. Secy., Albert C. Hale, 551 Putnam Ave., Brooklyn, N. Y.
AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.
Aug. 22-27. Annual meeting, Boston, Mass. Secy., F. W. Putnam, Salem, Mass.
GEOLOGICAL SOCIETY OF AMERICA.
Aug. 23. Annual meeting Boston, Mass. Secy., H. L. Fairchilds, Rochester, N. Y.
AMERICAN FORESTRY ASSOCIATION.
Aug. 23-24. Annual meeting, Boston, Mass. Pres., Francis H. Appleton, 101 Tremont St., Boston, Mass.
TECHNICAL SOCIETY OF THE PACIFIC COAST.
Sept. 2. Secy., O. Von Geldern, 819 Market St., San Francisco, Cal.
ENGINEERS' SOCIETY OF WESTERN NEW YORK.
Sept. 5. Secy., H. J. March, Library Bldg., Buffalo, N. Y.
ROADMASTERS' ASSOCIATION OF AMERICA.
Sept. 13. Annual meeting, Denver, Colo. Secy., J. B. Dickson, Sterling, Ill.
CENTRAL STATES WATER-WORKS ASSOCIATION.
Sept. 27-29. Annual meeting, Springfield, O. Secy., John Fisher, 11 Riley St., Hamilton, O.
AMERICAN INSTITUTE OF MINING ENGINEERS.
Oct. 18. Annual meeting Buffalo, N. Y. Secy., R. W. Raymond, P. O. Box 223, New York city.

CENTRAL STATES WATER-WORKS ASSOCIATION.—The annual convention of this association will be held at Springfield, O., Sept. 27-29. It is expected that fully 200 delegates will attend.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES.—The anuual convention of this association will be held at Sault Ste. Marie, Sept. 12-13. Arrangements are being made for a lake trip previous to the meeting, the Eastern members taking the boat, either the Northwest or North Land, at Buffalo and the Western members at Detroit.

THE WESTERN FOUNDRYMEN'S ASSOCIATION.—The regular monthly meeting of this association, held July 20, was devoted to discussing the papers read at the Cincinnati convention held June 23.

The first paper, "Trolley Systems in the Foundry," by Mr. Herbert M. Ramp was read by the secretary preparatory to its discussion. Mr. E. H. Putnam's paper, "Inspection of Castings," was then read and discussed.

NEW PUBLICATIONS.

LITERARY MAGAZINES.—Two of the great English reviews for July, the "Fortnightly" and "Nineteenth Century," give prominent place to articles discussing the new "era of good feeling" between Great Britain and America and its possible influence in International politics. Mr. Frederick Greenwood, in the last named magazine, is inclined to think that America will be glad to have England's help in her own complications, but if England wants aid in return she will get the cold shoulder. At the same time he thinks that if the United States is really setting out to become one of the great world powers, the day will come when she will need and welcome an alliance in which she can both give and get; and he esteems the fact that both nations happened to be looking for a friend at the same time and found one in each other, highly fortunate for both.

The following extract is interesting as showing how our attack of Spain is regarded by European nations:

> . . . . when the American Republic assaults a European State upon extra-legal grounds the door is opened for similar attack by Europe on the American Republic. A spell of immunity surrounded her; she reads the charm backwards and the spell is broken. For the people of the United States should remember that their justification of moral impulse is by no means unchallengeable. Its existence is openly denied by some of their own most learned and lofty minds. And if Europe were to say that here is a case where one country nurses insurrection in another, and then founds a moral right of invasion on the consequences, it could make out a very strong argument, which many commercial Americans are aware of.

An anonymous writer in the "Fortnightly" takes even stronger ground in urging that the United States will never repay the moral support which England has given in the present struggle; and thinks that England wants either an out and out alliance with this country or else no connection whatever.

In the same magazine Hon. T. A. Brassey discusses the question: "Can England Hold Her Own at Sea," and expresses the opinion that England's Navy is at present superior to that of any two powers combined, and this superiority can be maintained. He questions, however, whether the nation is strong enough to keep the fleet equal in strength to the fleets of three powers combined, and looks to the federation of England's colonies and a possible future alliance with the United States as the best means of securing the nation's safety. "The Nineteenth Century" also has a valuable statistical paper on the "Coal Supplies of the World."

In the "Pall Mall Magazine" for July the series of articles on "The Evolution of Comfort in Railway Travel" is concluded with a finely illustrated description of modern American passenger travel by Mr. Angus Sinclair, in which especial reference is made to the great improvement in the lighting of passenger cars, which has resulted from the general introduction of the Pintsch gas system. H. W. Wilson writes on current naval problems, and says that in the present war the navies opposed to each other at the outset were not unlike in their relative strength what the navies of England and France would be if brought to battle at the present time. In the August number of the same magazine Admiral Colomb writes on the lessons of the present war and makes a very readable paper, though he makes such slips as calling our own Sampson, "Admiral Hampton." Although the article was written before the battle of July 3, Admiral Colomb did not hesitate to express his wonder at Cervera's tactics and prophesied that he would not escape from Santiago.

The August "Home Magazine" has a long paper entitled "Harnessing the Earth," in which a large number of the water power and electric transmission plants erected during the last few years in this country are described. The article had better have been called "Harnessing the Rivers."

In "McClure's" for August Lieut.-Col. A. S. Rowan tells of his adventurous ride across Cuba to Gen. Garcia's headquarters in May last, and Gen. Miles describes the field manueuvers of the Russian, German and French troops last autumn.

The more popular literary magazines are giving so much of their space usually devoted to "solid matter," to articles upon the war and the new territories into which the United States arms have been carried, that they have little to spare for articles on scientific or engineering topics. "The August Century," however, has two very brief articles deserving note here, one describing the system of forest preservation which has worked such wonders in India, the other by Mark Twain, entitled "The Austrian Edison Keeping School Again." It appears that Jau Szczepanik, the inventor of the new "telectroscope," and the application of photography to pattern designing, was a poor country schoolmaster. He could not get leave of absence to go to Vienna to market his invention, so he deserted. This lost him his position but gained him a fortune. Now, however, he is obliged to do compulsory military service for three years, according to the law, to which, naturally, he is much opposed at a time when he is just setting out on an inventive career, and the government is also loath to take the young man, who has done so much for the nation's fame, away from his work. This dilemma has been solved, not by an amendment of the law, or the passage of a special act; that is not the continental way; but by allowing the inventor to nominally turn schoolmaster again. As schoolmasters are exempt from military service, once in every two months Szezepanik must return to his native village and teach school half a day.

In the "Atlantic" Prof. Simon Newcomb begins a most interesting series of articles on "The Reminiscences of an Astronomer," describing a visit to England three decades ago, and many famous scientists of that day. "Harper's" for August has an article on the "Grand Canon of the Colorado," by T. M. Prudden, the well-known bacteriologist, which will interest any of our readers who have ever had occasion to explore this wild region of the Southwest.

In the "Popular Science Monthly" for August, Prof. Israel C. Russell, of the U. S. Geological Survey, writes on "Topographical Features Due to Landslides." He explains the occurrence of many foothills and of small lakes without outlets in the lava covered region of Oregon, Washington and Idaho, on the theory that they are due to landslides from the adjacent cliffs and mountain ranges.

CONSTRUCTION NEWS.

CONDENSED LIST OF CONTRACTS PENDING WITH DATE OF OPENING BIDS.

Bids to be opened.	Work. Place.	See Eng. News.
Aug. 4.	Electric railway franchise, Plainfield, N. J.	July 28
Aug. 4.	Bridge, Urbana, Ill.	July 28
Aug. 4.	Paving bonds, Carlsbadt, N. J.	July 28
Aug. 4.	Hospital building, Lockport, N. Y.	July 28
Aug. 4.	Bridge bonds, Jersey City, N. J.	July 28
Aug. 4.	Substructure, Brooklyn, N. Y.	July 28
Aug. 4.	Dam, tunnel, etc., Ogden, Utah. Advertised, Engineering News, July 21.	July 21
Aug. 4.	Addition to court house, York, Pa.	July 21
Aug. 4.	Water pipe, Cattaraugus, N. Y.	July 21
Aug. 4.	Macadamizing, Boston, Mass.	Aug. 4
Aug. 4.	Road work, Plymouth, Mass.	Aug. 4
Aug. 4.	Iron bridge, Easton, Pa.	Aug. 4
Aug. 4.	Dredging, Boston, Mass.	Aug. 4
Aug. 4.	Pipe sewers, Erie, Pa.	Aug. 4
Aug. 5.	Pier, Cleveland, O.	July 14
Aug. 5.	Engines (2), Concord, Mass. Advertised, Engineering News, July 28.	July 28
Aug. 5.	Sewers, grading, etc., Wilmington, Del.	July 28
Aug. 5.	Court house, Portland, Ore.	July 28
Aug. 5.	Arch bridge, Springfield, Tenn.	July 28
Aug. 5.	Hospital building, Zumbrota, Minn.	July 28
Aug. 5.	Levee work, Desha county, Ark.	July 28
Aug. 5.	Roadway (2,000 ft.), Ridgway, Pa. Advertised, Engineering News, July 28.	July 28
Aug. 5.	Brick paving, Sedalia, Mo.	Aug. 4
Aug. 5.	Gravel road, Peoria, Ill.	Aug. 4
Aug. 5.	Asphalt paving, Louisville, Ky.	Aug. 4
Aug. 5.	Altering steam dump, New York, N. Y.	Aug. 4
Aug. 5.	Dredging, New York, N. Y.	Aug. 4
Aug. 6.	Asphalt paving, Louisville, Ky.	Aug. 4
Aug. 6.	School building, Watertown, Mass.	Aug. 4
Aug. 6.	Bridge bonds, Brattleboro, Vt.	July 28
Aug. 6.	Ditch, Kenton, O.	July 28
Aug. 6.	Drainage ditch, Arthur, Ill.	July 28
Aug. 6.	Tile and excavating, Champlaign, Ill.	July 28
Aug. 6.	Street work, Mansfield, O.	July 14
Aug. 6.	**Dike, York River, Va.** Advertised, Eng. News, July 7 to 28.	**July 7**
Aug. 6.	Bridge work, Olympia, Wash.	July 21
Aug. 6.	Dredging, etc., Virginia. Advertised, Eng. News, July 7 and 14.	July 7
Aug. 8.	Sewers, Toledo, O.	July 21
Aug. 8.	School building, Peterson, Utah.	July 21
Aug. 8.	Street bonds, Lima, O.	July 21
Aug. 8.	Street work, Lafayette, Ind.	July 21
Aug. 8.	**Water pipe, etc., Winnipeg, Man.** Advertised, Eng. News, June 16 to 30.	**June 16**
Aug. 8.	Brick paving, Anderson, Ind.	July 14
Aug. 8.	Repairing asphalt, Cincinnati, O.	July 14
Aug. 8.	Bridge, Salem, Mass.	July 28

RAILWAYS.

ALABAMA.—Reports state that the Pioneer Mining & Mfg. Co. has completed the purchase of coal lands near North Birmingham, Ala., and that it will award contracts in about two weeks for the grading of a railway from its furnace plant at Thomas, Ala., to the new mines, about 3½ miles. Surveys have already been made; and it is proposed to build a standard gage line with heavy rail. Messrs. Thomas, of Catasaqua, Pa., are the managers of the company.

ALLEGHENY & WESTERN.—J. M. Floesch, Ch. Engr., Kittanning, Pa., writes us that this company has recently awarded contracts for bridge work along its line to the Pencoyd Bridge Co., of Philadelphia, Pa.; Jutte & Foley, of Pittsburg, Pa.; and the Keystone Bridge Co., of Pittsburg, as more fully described under Bridges.

ATLANTIC COAST LINE.—Surveys are now being made for an extension of this line from Denmark, S. C., to a connection with the Charleston & Western Carolina Ry. It is said that contracts will probably be awarded in September. F. Gardner, Ch. Engr., Wilmington, N. C.

BRANDON & SOUTHWEST.—The contract for the construction of this railway from Brandon to Turtle Mountain, and from Deloraine to Wakida, Manitoba, a distance of about 90 miles, is said to have been awarded to Robert Waddell, Trenton, Ont. The work is to be completed by Nov. 1, 1904.

CALIFORNIA.—Press reports state that work will be resumed next month on the proposed railway to be built from San Diego to the sulphur mines, about 70 miles south of Yuma, Ariz., via Tia Juana, Cal., and Yuma. An entrance will be made into San Diego over the National City & Otay Ry. at Tia Juana. A. J. Booth, of Pittsburg, Pa., is said to be one of the directors. J. A. Dubbs, Gen. Mgr. Mexican Sulphur Co., Pittsburg, Pa., informs us that nothing has yet been done towards building this line except to survey the route from mines to Southern Pacific Ry., near Yuma, 67 miles, and a route from mines to San Diego, 168 miles. It is impossible to tell when construction will begin; nothing further may be done. W. A. Hartt, Ch. Engr., Los Angeles, Cal.

CAPE FEAR & NORTHERN.—J. M. Bandy, Ch. Engr., Greensboro, N. C., informs us that Gibson & Carpenter, Holly Springs, N. C., were awarded the contract July 25 for grading 20 miles of this proposed line from Apex to Blanchards, via Holly Springs, a total distance of 60 miles. Work was to have begun July 27. The right of way has been secured for this first section of 20 miles, and the profile and longitudinal maps completed for the same. Pres., Benjamin Duke, Durham, N. C.

CHICAGO, PEORIA & WESTERN.—This company has been incorporated in Illinois, with a capital stock of $50,000, to build and operate a railway from Chicago through Cook, Will, Grundy, Livingston, Woodford, Tazewell and Peoria counties to Peoria, Ill., thence to Rock Island through the counties of Peoria, Knox, Henry and Rock Island and from Peoria to Rockford through the counties of of Peoria, Marshall, Bureau, Lee, Ogle and Winnebago. The incorporators and first board of directors are, C. H. Matthiesen, S. T. Butler, W. J. German, William Dickinson and C. L. Glass, all of Chicago.

CHINA.—Press reports state that Yung Wing, the Chinese-American, has obtained an extension of time for his concession for the Tien-Tsin-Chin-Kiang Ry., alleging that he has received the support of an English syndicate to supply the necessary capital, £5,000,000. It is also said that Hou Yu Fen, one of the directors general of the Chinese railways, in the face of Russian opposition to the loan, has broken off negotiations with the Hong Kong Bank, which proposed to supply the capital for building an extension of the Tien-Tsin-Shan-Haikwan Ry. to New-Chwang. The latter is distinct from Yung Wing's concession.

CHOCTAW, OKLAHOMA & GULF.—F. A. Molitor, Ch. Engr., South McAlester, Ind. Ter., informs us that this company has completed the location of its line from Shawnee to Stillwater, Okla., a distance of 64 miles. On the eastern extension, from Wister Junction to Howe, on the Kansas City, Pittsburg & Gulf R. R. track has been laid and the road has just been placed in operation. On the western extension track was laid to Geary and the road placed in operation on July 6; this is at a distance of 18 miles from Fort Reno, Okla. Since that time the track has been extended to the South Canadian River at Bridgeport and grading is in progress as far as Weatherford, a distance of 47 miles from Fort Reno, and it is expected that the line will be completed to Weatherford and ready for business on or about Sept. 15.

COLORADO & NORTHWESTERN.—J. S. Frankeberger, Ch. Engr., Boulder, Colo., informs us that this line will not be extended from Ward to Eldorado, Colo., this year. Pres., C. E. Thompson, Boulder, Colo.

DENVER & RIO GRANDE.—Press reports state that Orman, Crook & Co., of Pueblo, Colo., are at work on the proposed extension of this line from Leadville to Ibex, Colo. It is expected to complete the work in 90 days.

EAGLE VALLEY & BAKER CITY.—S. R. Reeves, Pres., La Grande, Ore., informs us that the preliminary survey has been made and the right of way obtained for this proposed line of railway from Baker City to the Seven Devils mining camp, via Sparta and Pine, Ore., a distance of 70 miles. The capital for construction has not yet been secured, and if it be not obtained soon, it is not likely that the road will be built. Mr. Howe, of Baker City, is chief engineer.

ELLAVILLE, WESTLAKE & JENNINGS.—This company is said to be extending its line for a distance of 13 miles. It is now in operation between Ellaville and Johnson, Fla., 20 miles, and the extension is towards Jennings. E. E. West, Pres. and Gen. Mgr., Westlake, Fla.

EMMITSBURG.—It is announced that the directors of the Emmitsburg R. R. Co., which bought the seven miles of road running from Rocky Ridge, where it connects with the Western Maryland R. R., have reorganized and elected the following officers: Pres., James A. Elder; Vice-Pres., William A. Hines, New Oxford, Pa.; Treas., William G. Blair; Secy., Dr. J. B. Brawner; Counsel, Vincent Sebold. In the near future the company contemplates extending the road on to Woodsboro, where it will connect with the Pennsylvania system and give direct communication with Frederick City, Md.

FLAT RIVER VALLEY.—This company was incorporated in Missouri, July 28, with a capital stock of $600,000, to build and operate a standard gage railway from the Mississippi River, in Perry county, opposite Chester, Ill., and through the county of Ste. Genevieve to Farmington, in St. Francis county, and thence to Irondale, on the Iron Mountain R. R., in Washington county, a distance of 60 miles. The incorporators are: C. B. Cole, C. H. Shannon, Edward Whitaker, H. J. Cantwell and Charles Hamilton.

GULF & BRAZOS VALLEY.—Reports state that tracklaying will begin on this proposed line, from Henrietta to Velasco, Tex., 400 miles, in about two months. About 20 miles have been graded and the bridges are being erected. Pres., W. A. Squires, Lakota, Tex.

INDIANOLA COAL & RY.—This company was incorporated in Texas, July 21, with a capital stock of $250,000, by C. H. Alexander, Emmett A. Ellis and R. C. Hawley. The principal place of business will be at Dallas, Tex.

KANSAS, OKLAHOMA CENTRAL & SOUTH WESTERN.—The citizens of Cherryvale and Caney, Kan., voted to issue $20,000 and $10,000 in bonds respectively at a special election July 19, to aid in the construction of this railway, which is being built from Cherryvale, Kan., to Vernon, Tex., a distance of 350 miles. Independence, Kan., was to have a special election Aug. 2 to vote $13,000 in bonds for the same road. Pres., J. H. Bartles, Bartlesville, Ind. Ter.

LEHIGH VALLEY.—This company is said to have made a contract with A. G. Morris & Co., of Tyrone, Pa., for reballasting the entire double-track roadbed from Buffalo to New York with crushed stone; the stone will be quarried at Le Roy, N. Y. C. E. Webster, Ch. Engr., South Bethlehem, Pa.

MINNESOTA, IOWA & GULF.—This company was incorporated in Iowa, June 27, with a capital of $10,000. It is proposed to construct a railway from New Ulm, Minn., to Conception, Mo. The incorporators are, J. J. Bell, A. C. Titus, J. H. Dixon, Frank T. Campbell and Samuel Compton, of Des Moines, Ia.

MORRISTOWN & CUMBERLAND GAP.—We are informed that the survey will soon be started for the proposed extension of this line, from Bristol towards Knoxville, Tenn. This line is a branch of the Knoxville & Bristol Ry., of which B. J. Woodward, of Philadelphia, is president.

MUSCATINE, NORTH & SOUTH.—E. A. Tennis, of Philadelphia, Pa., according to press reports, has been awarded a contract for the construction of 30 miles of railway for this company, from Muscatine to Elrick, via Grandview and Wapello, Ia. The work is expected to cost about $450,000, and is to be completed by Jan. 1, 1899.

NORFOLK & WESTERN.—Reports state that two corps of engineers are now at work surveying a line of railway from the Elkhorn division of the Norfolk & Western, up Dry Fork or Sandy, towards Tazewell, Va., which will develop a large area of the finest coal in all this section, and it is stated that there is no question now of its construction. It is also said that the road will run to within about twelve miles of Tazewell, which will make it an easy matter to connect with the Clinch Valley division of the Norfolk & Western. J. M. Barr, Gen. Mgr., Roanoke, Va.

NORTHERN PACIFIC.—The directors of this company have authorized the construction of an extension of its Rocky Fork branch through Carbon county, from Rockvale, Mont., in a southerly direction up the valley of Clarke's Fork River, 20 miles to the Bridger coal fields, which is to be the other terminus of the road.——Press reports state that a large force of men and teams and the work train of this company are now at the Cedar Creek side track, three miles south of Garfield, Wash., and will begin at once on the work of filling the big trestle across Cedar Creek. This is the largest and highest trestle on the Spokane & Palouse branch, and the contract of filling this with rock and earth will be a large one. It is said the estimated cost of this work is $28,000. Two large stone arches are to be erected, one for the wagon road and the other for the creek, and when this is completed the Spokane & Palouse branch will have nearly a solid roadbed the entire length of the road. Another large trestle south of Cedar Creek was filled last year, but this has settled some and more work will be done on this soon. It is hoped to have the fill at Cedar creek completed before next winter. E. H. McHenry, Ch. Engr., St. Paul, Minn.

PHILADELPHIA & EASTERN.—The charter granted to this company on January 31 was accepted by the incorporators on August 1; capital stock, $250,000. It is proposed to construct a steam railway through Philadelphia and Bucks counties, Pa., to connect with the Philadelphia, Newtown & New York R. R. below Foxchase, a suburb of Philadelphia, to a point on the Delaware River opposite Trenton, N. J., a distance of 20 miles. The incorporators are: Pres., Lamar J. Ridge; John S. Hoffman, J. T. Ridge, M. D.; Albert W. Margerum and Clarence Hampton, all of Philadelphia, Pa.

ST. FRANCOIS VALLEY.—We are informed that this line was to be open for business on Aug. 1, or as soon as the crossing over the St. Louis Southwestern Ry. was put in. The route is from Campbell to Caligoa, Mo., 10 miles. Pres., E. F. Blomeyer; Ch. Engr., Jas. F. Brooks, both of Cape Girardeau, Mo.

SAN FRANCISCO & SAN JOAQUIN VALLEY.—W. B. Storey, Jr., Ch. Engr., 321 Market St., San Francisco, Cal., informs us that this line was opened for operation to Bakerfield, Cal., 235 miles from Stockton, on June 1. The road has been graded from Visalia to Junction, with a line south from Hanford, a distance of 24 miles. Tracklaying has just begun on this piece. Work on the Franklin tunnel is progressing satisfactorily, and grading has been well advanced for six miles on each side of the tunnel. It is also reported from San Francisco that Frank S. Boggs has been awarded a contract for grading two miles of the road on the extension west of Stockton, and that additional grading contracts will soon be let.

ST. LOUIS & OKLAHOMA.—We are informed that 95% of the grading has been completed on this new line from Sapulpa, Ind. Ter., to Oklahoma City, Okla., via Stroud, Chadler and Wellston, 103½ miles. Track has been laid on the 20 miles west of Sapulpa. J. F. Hinckley, Ch. Engr., Sapulpa.
